ENGINEERING NEWS

AND

AMERICAN RAILWAY JOURNAL

VOLUME XL.

JULY-DECEMBER, 1898.

THE ENGINEERING NEWS PUBLISHING COMPANY

NEW YORK.

SUPPLEMENT TO ENGINEERING NEWS, DECEMBER 29, 1898.

REMOTE STORAGE

3

INDEX

TO VOLUME XL, JULY-DECEMBER, 1898.

Subdivided into ILLUSTRATIONS: GENERAL (including *Editorials, Technical Articles, Current News* and *Correspondence*): AUTHOR: BOOK REVIEWS and TABLE OF ERRATA. (Also CONTRACT PRICES of Supplement.)

INDEX TO ILLUSTRATIONS.

A.

Abutment, N. Y. C. & H. R. Ry., Buffalo. 34
Aerating and overflow chamber 325
Air blast transformer 12
Air compressor, Duplex Corliss.......... 160
Air locks:
  Hughes 362
  Wooden caissons. 364, 365
Anchor, Concrete, for jetties and buoys. 15
Angle connections of structural beams... 43
Angle straightening roll *194
Anti-creeper for rails 244
Aqueduct, Steel, Briare Canal.......... 283
Arches:
  Hennebicque steel and concrete....302, 315
  Melan concrete 290, 291
  Merrick circular 221
Asphalt lining of reservoir 325
Asphalt plants:
  Cincinnati, Portable 217
  Hetherington portable 162

B.

Battery, Jacques carbon, Testing apparatus 198
Battleship "Maine" *315, 316
Beams:
  Angle connections 43
  Tests 203, 204
Bilge keel fitted to battleship 309
Billet shears, Hydraulic 195
Blowing engine, Hungary *302
Boiler, Belpaire, for locomotive 142
Bolster and truck, American............ 166
Breakwater construction on American coast 122
Bridge floors, Wood block, France....... 84
Bridges:
  Buffalo, Concrete abutments 34
  Concrete, Hyde-Park-on-Hudson 290
  Concrete and metal foot bridge 45
  Cornwall, Ont. 419
  Davis Ave., Allegheny City, Pa........ 134
  East River, New bridge 66
  Fairmount Park, Philadelphia.......... *67
  Interlocking machinery for operating draw 6
  Kan. City, Pitts. & Gulf. Ry......*114, 347
  Milwaukee Lake Park 98, 99
  Muengsten steel arch *139
  N. Y. & Ottawa Ry., Failure 174
  Niagara stone arches 410
  North Ry., Paris 30
Buildings:
  Omaha exposition 2, 5
  Veeder Mfg. Co.. 15
Bulkhead doors, Cowles hydraulic system. 101
Bulkheads, Tests of 311
Bushed pin connection for steel arch 103

C.

Caissons:
  Cincinnati water-works *354
  Wooden pneumatic 363, 365
Canal aqueduct, Steel 283
Canal entrance, Duluth harbor........... *50
Canals:
  Bruges, Belgium 402, 403
  Erie, Earth slips 338
  Nicaragua 211, 212
  Panama 210, 212
  St. Lawrence Power Co...............*373
Car and engine replacer 87
Cars:
  Dump:
    Goodwin 306
    Page sectional 389
  Dynamometer 335
  Furniture *259
  Meat distribution, Buenos Ayres 206
  Poling, Penn. Ry 229
Charging machinery,. Electric............*194
Chimney, Highest in America 140
Clamp connection for staging construction. 103
Clutch, Magnetic, in Arnold System 28
Coal breaker, Hazleton, Pa..............*392
Coal storage plant of Lehigh Coal Co.... *99
Columns, Appraisers' warehouse, N. Y.. 279
Concrete mixer, Albany, N. Y...........*254
Coupler for air brake and signal pipe .. 266
Coupling shoes for wood stave pipe..... 261
Cowles system of watertight bulkhead doors 101
Cribs:
  Bridge pier crib and apron 117
  Intake, Cleveland, O................ *82
  Retaining, Lake Superior Power Co ... 68
Crusher, Preston double-acting 395

D.

Dams:
  Brick and concrete, New South Wales. 148
  Council Grove highway 372
  Croton, N. Y........................*243
  Hobbs Brook reservoir 324
  Hudson River Power Co 130
  Hydraulic method of building 242
  Poiree needle, Louisa, Ky............. *2
  Rock-fill, California 63
  Snake River, Cal. 242
Diagrams:
  Bazin hydraulic formula 27
  Calorific value of coals in relation to proximate analyses 382
  Capacity and loading of power station, Scott Haven, Pa.................. 109
  Cost of operation of street railway power stations 182, 183
  Diesel motor 422
  Engine indicators 53
  Frog angles 58
  Johnson's straight line formula for determining the strength of columns.*178
  Load curve of power station of a city street railway 170
  Logarithmic diagrams in calculating flow in conduits under pressure... 179
  Losses of heat in steam plant 249
  Paving brick tests 85
  Soil temperatures, Effect of irrigation on 383
  Stony Brook conduit 11
  Thermal stress curve of boiler plate steel 155
  Transverse strength of railway rails...*180
Discharge regulator on redwood water main. 159
Domes:
  Steel dome and spire, Chicago......... 231
  Yerkes observatory *18
Draft rigging, Freight car 149
Dredge, Hydraulic suction 374
Dry docks, Cleveland Ship Building Co. 150, 151
Dump cars:
  Goodwin 306
  Page sectional 389
Dumping wagon with automatic tailboard 206
Dynamometer car 335
Dynamos:
  Hudson River Power Co 132
  Walker, Lake Superior Power Co...... 70

E.

Earth slips on Erie Canal 338
Electric donkey for operating turntable. 119
Electric motor for narrow gage railway. 93
Electric railways:
  Central Lincoln Ry. tunnel 411
  Chic. & Mil., Maps 125, 126
  Jungfrau 370
  Walker conduit system 71
Electric welding of street railway rails.78, 79
Electrolysis of rails 293
Elevator counterweights, Manice building, New York 379
Elevators, Electric, London Underground Ry.........................*274, 277
Engine indicator 52
Engines:
  Gas, Double-cylinder 178
  Hoisting 45, 62
  (See also Steam engines.)
Excavator, "Orange-peel" *373
Eye-bar upsetting machine, Hydraulic... 197

F.

Feed pump, Blake "Simplex"........... 334
Feed-water filter, Ross 406
Filter beds:
  Sewage, Central Falls, R. I............ 133
  Water purification:
    Albany, N. Y. 254
    Covered, Somersworth, N. H. 358
Fireproof construction, Appraisers' warehouse, New York 279
Fireproof screen 279
Fireproofing plant, Wood 308
Floors:
  Appraisers' warehouse 279
  Filter beds, Albany, N. Y............. 254
  Fireproof systems in London 390, 391
  Hennebicque arch system 302, 315
  Merrick fireproof 221
  Wood block, on bridge 84
Fly-wheel rims 350
Forge, Portable........................ 349
Forming machine, Hydraulic, Eye-bar plant *194
Freight car draft rigging 149
Frog angles, Diagram of................ 58
Frogs, Spring-rail 357
Furnace, Rotary roasting 310

G.

Gantry carrying eight radial drills......*194
Gas engine, Double-cylinder 178
Gas holder wreck, New York........... 407
Gasoline engine and hoisting plant...... 62
Gate-house, Payson Park reservoir...... 325
Girders:
  Model, Effect of weights 90
  Vierendeel. 378
Grade crossings, Chicago, Plans and cross sections 22, 23
Guard rails, Angle iron 357
Guns, Sims-Dudley pneumatic.......... 86

H.

Harbor at Heyst, Belgium 402
Head frame for mine shaft 292
Hoist, Ten-ton electric traveling 195
Hoisting and distributing plant, Sherman 254
Hoisting engines:
  Gasoline 62
  Safety appliances 45
Hoisting machines for electric elevators. 275

I.

Indicators:
  Atwood 245
  Engine, Continuous recording 52
  Testing apparatus 380
Insets:
  Battleship "Maine" *315, 316
  Blowing engine, Hungary *302
  Bridges:
    Fairmount Park, Philadelphia *67
    Kansas City, Pitts. & Gulf Ry. *114
    Muengsten, Ger. *139
  Budapest power house. *339
  Canal entrance, Duluth *50
  Cars, Furniture *259
  Coal breaker, Hazleton, Pa. *392
  Coal storage plant of Lehigh Coal Co.. *99
  Dams:
    Croton, New York *243
    Louisa, Ky......................... *2
  Diagrams:
    Finding transverse strength of rails..*180
    Johnson's formulas *178
  Dome of Yerkes' Observatory.......... *18
  Elevators, London Underground Ry. ..*274
  Intake tunnel, Cleveland, O.......... *82
  Locomotives, European and American.*298
  Marine wood borers *34
  Pencoyd Iron Works *194, 197
  Pumping engine *322
  Railways:
    Berlin, Metropolitan and belt lines...*213
    Cripple Creek mining district *156
  St. Lawrence Power Co.'s canal *373
  Santiago de Cuba maps *227
  Triangulation of United States *340
  Trucks, Metal *164
  Water purification plant, Albany, N. Y.*254
  Water-works, Cincinnati *354
Insulators:
  Boch high potential 51
  Osgood 339

J.

Jacques' carbon battery, Testing apparatus 198
Joints:
  Pipe, Coolgardie line 233, 423
  Rail:
    Bonzano 224
    Heath improved 333
Jungfrau Mountains 370

K.

Keely, J. W., Portrait 336

L.

Lever latch for hoisting drum of derrick engine 45
Lever lock for foot brake, derrick engine. 45
Locomotives:
  Consolidation freight, B. & M. R. Ry. 141, 142
  Consolidation pusher engine 332
  Electric:
    Erie Ry. 158
    Heilmann. 326
    Jungfrau railway 371
  European and American *298
  Largest ever built 258
  Switching, Harlem Transfer Co. 401
  Ten-wheel passenger 50
Losses of heat in steam plant 249
Lumber yards 307

M.

Maps:
  Chic. & Mil. Electric Ry. 125
  Cripple Creek mining district......... 157
  Panama and Nicaragua canals 212
  Santiago de Cuba and vicinity *227
  Water power plant, Lake Superior Co. 68
Marine wood borers *34, 37
Meat distribution by electric cars 206
Merritton tornado. 226
Meter recording blank 179
Mining machine, Calhoun placer........ 55
Mortar-mixer, Steinbruck 14
Motor, Electric, Narrow-gage railway... 93
Motor vehicles:
  Jeantaud cab 386
  Jeantaud landaulet 387
  Jenatzy coupe 386
  Krieger victoria 387
  Peugeot coupe 386

N.

North Pole, Positions of, 1890-97........ 95

O.

Omaha exhibition buildings 2, 5

P.

Pack, Making and carrying of........... 418
Paving brick tests 85
Pencoyd Iron Works *194, 197
Penstock construction, Lake Superior Power Co. 70
Piers, Concrete, Arkansas River bridge. *114, 117
Pin connection, Bushed, for steel arch... 103
Pipe covering, Air cell 342
Pipe joints, Coolgardie line 233, 423
Placer mining machine 55
Planer, Double-head rotary.............*194
Plate girders:
  Method of testing, to determine nature of web stresses 155
  Tests of stress in stiffeners........... 186
  Web stresses 400
Poling car, Penn. Ry. 229
Power gage, Atwood 245
Power houses:
  Chic. & Mil. Electric Ry. 127
  Hudson River Power Co. 130
  Lake Superior Power Co. 69
Pumping by compressel air 267
Pumping engines, Ogdensburg, N. Y.*322, 323
Pumps:
  Blake boiler feed 334
  Centrifugal, on hydraulic dredges 236, 239
  Conoidal centrifugal 340, 341
  Electrical equipment 93
Punching machines:
  Multiple beam 196
  Spacing punch *194
Pyrometer for measuring temperature of molten iron 268, 269

R.

Rail bond, Protected, C. & M. Electric Ry. 126
Rail brace chair, Renson's 118
Rail fastening, Post's improved......... 119
Rail joints:
  Bonzano's new device............... 244
  Heath improved 333
Rail welder, Thomson electric 78, 79
Rails:
  Anti-creeper 244
  Electrolytic corrosion 293
  Rack, Jungfrau Railway. 371
Railway station, Pittsburg, Penn. Ry.... 316
Railway surveying party 412, 413
Railways:
  Berlin, Metropolitan and Belt lines....*213
  Cripple Creek mining district *156
Replacer, Car and engine 87
Reservoirs:
  Asphalt lining, Placing 325
  Cambridge, Mass.. ....324, 325
Revetment for canal prism in earth 69
River, Chicago, Obstructive works 44
Rivet steel, Apparatus for testing shearing strength 100
Riveter, Hydraulic, with electric traveling gantry. 195
Roadbed, C. & M. Electric Ry.......... 126
Roasting furnace, Rotary 310
Rock crusher, Hot air 388
Ropes, Wire, for hoisting 382

S.

Safety appliances for derrick engines.... 45
Santiago de Cuba, Maps................*227
Scale, Universal circular 359
Scraper, Vivian power *373
Screen, Fireproof 279
Sedimentation basin, Albany, N. Y......*254
Settling basins and connections, Ft. Smith, Ark.......................... 107
Settling tanks, Central Falls, R. I....... 133
Sewage purification, Central Falls, R. I. 133
Sewers:
  Steel pipe, Thames River bridge....... 21
  Wooden lining, Melbourne, Aus........ 410
Shipyard, Cleveland Shipbuilding Co.,150, 151
Signals:
  Lake Shore & Mich. So. Ry. 67
  Locomotive cab 263
Spacing punch, Automatic *194
Staging, Traveling inspection, Muengsten bridge 139
Staple, Drop-forged hitching staple for mine cars 393
Steam engines:
  Atwood power gage 245
  Berlin Electric Works 114, 115
  Budapest power house *339
  Compound blowing engine *302
  Oscillating piston 29
Steam shovel work *373
Steamers:
  "Berkeley," So. Pa. Co...........414, 415
  "Pathfinder" 333
  Sinking of "Tal Hoku" 18
Stone crusher, Preston double-acting... 395
Storage room, Youngstown Bridge Co.... 82
Stresses:
  Plate-girder web 400
  Railway rails under moving trains.... 214
Subway, Boston, Ventilation 333
Switches, 100-lb. rail 356
Sewers, Steel pipe, Thames River bridge 21

607171

T.

- Tail-race pit, Lake Superior Power Co. 69
- Teredo navalis *34, 35
- Terminal yards of Harlem Transfer Co. 401
- Tie-plate, Q. & W. 381
- Ties, Steel, Netherlands, State Rys. 118
- Tornado at Merritton, Ont. 226
- Track elevation, Erie Ry., Jersey City. 110
- Track gages 190
- Train order annunciator 263
- Transformer, Air blast 12
- Trucks, Metal, for freight cars *164
- Truss, Waddell's "A" type 116, 346, 347
- Tunnels:
  - Central London Ry. 411
  - Intake, Cleveland, O. *82
- Tunnels. (Continued.)
  - Wood lining, Melbourne, Aus. 410
- Turntables, Electric donkey for operating 119

V.

- Valves:
  - Pumping engine 322, 323
  - Reducing valves, New 78
  - Rotary, 48-in. 149
  - 60-in. hydraulic 420
- Veeder Mfg. Co., Building 15
- Ventilating fan, Boston subway 333
- Viaduct wreck, St. Paul, Minn. 398

W.

- Walker conduit system 7
- Waring, Geo. E., Jr., Portrait 284
- Warships:
  - "Infanta Maria Teresa" 332
  - "Maine," New *315, 316
- Water pipes:
  - Coupling shoes 261
  - Expansion joint, Coolgardie line 233
- Water power plants, Lake Superior Co. 68
- Water purification:
  - Albany, N. Y., plant *254
  - Wilmington, Del., plant 146
- Water softening plant 404, 405
- Water-tight bunker door operated by Cowles' hydraulic system 101
- Water-wheels:
  - Hug impulse 327
  - Impulse, 30-ft. diameter 253
  - Theory of 37, 38
- Water-works:
  - Cambridge, Mass. 324, 325
  - Cincinnati, O. *354
- Welding, Electric, of street railway rails. 78, 79
- Wharf construction, Lake Superior Power Co. 68
- Wire ropes for hoisting 382
- Wood borers, Marine *34, 37
- Wood fireproofing plant 309

Y.

- Yards, Terminal, Harlem Transfer Co. 401
- Youngstown Bridge Co., Storage room 82

GENERAL INDEX.

A.

- Abrading material, New 267
- Abutments, Concrete, Buffalo bridge 34
- Accidents:
  - Boiler explosions:
    - Locomotive boilers 113, 257
    - National Starch Mfg. Co. 46
    - River steamer, Stockton, Cal. 337
    - Torpedo boat "Davis" 257
  - Bridges:
    - Cornwall, Ont., Failure 145, 174, 202, 289, 419
    - Shelby, O., Failure 1
  - Cloud-burst, Rogersville, Tenn. 97
  - Electric railway, Wash., D.C., Collision 17
  - Elevator, New York city 353, 379
  - Explosions:
    - Ammunition, Havana 337
    - Boilers, 46, 113, 257, 337
    - Celluloid, Newark, N. J. 145
    - Gas, United States Capitol 289
    - Grain dust 177, 193, 207
    - Gunpowder 17, 353
    - Harbor mines 145, 353
    - Mine, Brownsville, Pa. 207
  - Fires:
    - Hazen, Allen, Office at Albany, N. Y. 385
    - Home Life Insurance Co., New York 366, 396
    - Jerome, Ariz., destroyed 177
    - San Francisco, Cal., hotel 348
    - Steamer "Delaware" 17
  - Floods in Japan 257
  - Gas tanks:
    - Baltimore, Md. 369
    - New York city 369, 406
  - Grade-crossing, Cohoes, N. Y. 145
  - Hospital ship "Bay State" 353
  - Hurricane at Barbadoes 177
  - Locomotove boiler explosions:
    - Santa Fe, Prescott & Phoenix Ry. 113
    - Wilmington & Northern Ry. 257
  - Mines:
    - Explosion at Brownsville, Pa. 207
    - Fall of cage, Wilkesbarre, Pa. 289
  - Railways:
    - Balt. & Ohio, Foley's, Pa. 17
    - Bost. & Maine, South Berwick, Me. 337
    - Central of Georgia, Ft. McPherson, Ga. 65
    - Clarion River, Portland Mills, Pa. 369
    - Den. & Rio Grande, Black Canyon, Colo. 177
    - Florida Central & Peninsular 385
    - Genoa, Italy, Glori tunnel 97
    - Grand Trunk, Trenton, Ont. 305
    - Illinois Central, Vine Grove, Ky. 1
    - Lehigh Valley, Wilkesbarre, Pa. 305
    - Louisville & Nashville 97, 129
    - Midland Ry., England 207
    - N. Y. C. & H. R., Grimesville, N. Y. 385
    - N. Y., N. H. & Hartford. 81, 113
    - N. Y., O. & W., Fulton, N. Y. 145
    - Penn. Ry. 321, 409
    - Rock Island, Fort Worth, Tex. 257
    - Southern Pacific, Dutch Flat, Cal. 49
    - Texas & Pacific, Jefferson, Tex. 161
    - Union Pacific, Omaha, Neb. 273
    - Wisconsin Central, Ashland, Wis. 193
  - Stand-pipe, Waco, Tex. 241
  - Steam pipe, Washington D. C., Lighting plant 369
  - Steamers:
    - "Alamo," Pipe burst 353
    - "Aurania," Broken shaft 177
    - "Bay State," Explosion on 353
    - "Croaton" burned 289
    - "Delaware" burned 17
    - "Friesland," Broken shaft 49
    - "L. R. Doty" lost on Lakes 273
    - "La Bourgogne" lost. 1, 25. 65
    - "Lucania," Broken piston rod 17
    - "Mohegan" lost. 241
    - "Portland" lost 348
  - Theatre roof collapsed, Detroit, Mich. 289, 369
  - Viaduct wrecked, St. Paul, Minn. 396, 398
  - Water pipes:
    - Brooklyn, 48-in. main breaks 369
    - Cleveland, O., Breaks 409
    - Philadelphia, Pa. 369
    - St. Louis, Mo. 369
  - Water-works tunnel, Cleveland, O. 17
- Acetylene:
  - Bost. Mfr. Mut. Ins. Co.'s circular 305
  - Car lighting, Pon. Pac. Junction Ry. 178
  - Public lighting plants:
    - Milford, Pa. 285
    - New Milford, Conn. 79
    - Wabash, Ind. 208
- Acoustic Co., National, organized in Buffalo 213
- Aerating and overflow chamber 324
- Air:
  - Dielectric strength of 47
  - Discovery of new elements 208
- Air-brake and signal hose coupler 266, 314
- Air-brake triple-valve patents 202
- Air-brakes:
  - Equipment of freight cars, 1898 177
  - Instructions for handling brakes 190
  - Westinghouse, for Russian Government 31
- Air compressors, Lassig Bridge & Iron Works 159
- Air locks:
  - Hughes, Valparaiso harbor 362
  - Wooden pneumatic caissons 363
- Alaskan gold fields 32
- Alternating currents, Determining the frequency 143
- Aluminum transmission lines 129
- American Association for the Advancement of Science 142, 204
- American Institute of Architects 304
- American Institute of Electrical Engineers 46
- American Institute of Mining Engineers 269
- American R'lw'y Engineering and Maintenance-of-Way Association 280, 330
- American Society of Civil Engineers:
  - Convention at Detroit, Mich. 80
  - Nomination of Desmond Fitz-Gerald 232
- American Society of Heating and Ventilating Engineers 47
- American Society of Mechanical Engineers 351, 368
- American Society of Municipal Improvements 287
- American Street Railway Association 175
- Anchor, Concrete, Atlantic City, breakwater 15
- Angle connections, Structural beams 43
- Anti-creeper for railway tracks 244
- Aqueducts:
  - Steel, Briare Canal, France. 283
  - Stony Brook conduit, Boston, Mass. 11
  - Wachuset, Boston, Tightness 19
  - Washington, D.C., Volume of flow 20
- Arc at the equator 351
- Arc lamps:
  - Cost of street lighting in U. S. 102, 154
  - Photometry of enclosed arc 215
  - Submarine, Test, Brooklyn Navy Yard 209
- Arches:
  - Brick, Lake Park bridges, Milwaukee 98
  - Hennebicque system, concrete and steel 302, 315
  - Melan system, Hyde Park-on-Hudson 290
  - Steel:
    - Ornamental bridges, Milwaukee 98
    - Railway bridge, Muengsten, Ger. 139
  - Terra cotta:
    - Appraisers' warehouse, New York 278
    - Merrick fireproof floor 221
- Architects, Meeting of, Washington, D.C. 304
- Arctic expeditions, Peary 224
- "Arithmetic of the Steam Engine" 58, 89 106
- Armor plate:
  - American, in Spanish-American War 295
  - Russia, Rolling machinery wanted 353
  - 12-in. Krupp process, Test 193
- Army camps, Typhoid fever and water purification 104, 184, 251
- Army transports, Proposed to transfer to control of Navy 216
- Arnold system of connecting engines and generators 28
- Aspen, Colo., Notes of an engineer 331
- Asphalt plants:
  - Cincinnati, O., Portable plant 217
  - Hetherington portable 162
  - New York, Municipal plant recommended 187
- Assessments:
  - Sewer, in Boston 229, 232
  - Street and railway, in Mass. 55
- Association of Railway Superintendents of Bridges and Buildings 271
- Astromomical Society, National, in U. S. 160
- Atlantic Transportation Co., of New York 209
- Atmospheric resistance to motion of trains 39
- Axles, Breakages of electric car axles, Tacoma. 42

B.

- Bacterial analyses of public water supplies, Value of 72
- Balloon in warfare, Value of 145
- Baltimore "Board of Awards" 328, 361
- Bank vaults, Armor plate 81
- Battery, Jacques, converting heat into electricity 197
- Battleships. (See Warships.)
- Bazin's formula for computing flow of water in open channels 26
- Beams:
  - Concrete and steel, Formula for fiber stresses. 298
  - Erroneous data in manufacturers' hand-books 43, 203
- Belt tensions, Variation of, with power transmitted 368
- Bethlehem Iron Co., Visit of engineers 319
- Bilge keels and rolling experiments 309
- Bins, Pressure of stored coal in 100
- Blast-furnace methods and practices 270
- Blast-furnace slag, Granulated 135
- Block system:
  - "Boot-jack" signals, L. S. & M. S. Ry. 66
  - New South Wales 129

LETTERS TO THE EDITOR 10
- The Graham Automatic Drawbar Height Adjuster—Correction—A Theory for Placing Stiffeners in Plate Girders—A Visit to the Virginia Military Institute—The Design of Extensions to the Stony Brook Conduit, Boston, Mass. (illustrated)—The New York Fireproofing Tests.

THE PLANS FOR THE FOUR NEW MONITORS, authorized in the last naval appropriation bill, call for the following general dimensions: Length on normal load water line, 225 ft.; extreme beam at water line, 50 ft.; mean draft at normal displacement, 12½ ft.; normal displacement, about 2,700 tons; total coal capacity, loose stowage, 200 tons. They are to be harbor-defense vessels and are to cost not more than $1,250,000, exclusive of armament. They must be built within 27 months from time of contract. The hull will be of steel, unsheathed, with double bottom and water-tight divisions; there will be one military mast. The side armor belt will be 11 ins. thick and taper to 5 ins. at the ends; it will be 5 ft. deep. The barbettes for the 12-in. guns will be 11 ins. thick; the protective deck will be 1½ ins. thick and the conning tower 7½ ins. thick. There will be two vertical triple-expansion engines, operating twin screws, and four water-tube boilers working up to 250 lbs. steam pressure. Two 12-in. guns will be mounted in a barbetted turret amidships forward, with four 4-in. rapid-fire guns in broadside on the superstructure deck, and a secondary battery of seven rapid-fire guns. The ship must develop a speed of 12 knots for two consecutive hours, with a penalty of $5,000 per quarter knot below that to 11 knots; if the speed is below 11 knots the vessel will be rejected.

◆

THE CLIMATE OF CUBA AND MANILA is made the subject of a special report by W. F. R. Philips, of the U. S. Weather Bureau. In both cases the sources of information are very meager; those of Cuba being practically confined to Havana. At this place the highest temperature recorded in ten years is 100.6° F., while it has been 104° F. at Washington, D. C., in that period. The mean annual temperature at Havana, for the years 1888-97, is about 77° F. July is the warmest month, with an average of 82.4° F.; in January the average is 70.3° F. At Santiago de Cuba, the only data available would indicate a mean temperature of 80° F., with a range of only 6° between the hottest and coldest months. The average diurnal range in temperature about Havana is about 10°. The average Havana rainfall is about 52 ins. per year, and the rainy season occurs between May and October, with the greatest rainfall in October and the next greatest in June. The relative humidity averages about 75% of saturation and is practically constant for the year; the absolute humidity is very great; the Havana average is about 7.5 grains of vapor to one cubic foot of air. This varies from 6.2 grains in January to 8.9 grains in September. On the average rain falls in one day out of three at Havana, with heavy down pours of short duration as the characteristic. The heaviest daily rainfall recorded is 6.27 ins. in May and 5.32 ins. in October. The average wind velocity at Havana, from the "Northeast Trades," is 7.5 miles per hour, varying from 8.5 to 6.5 miles. The heaviest tropical storms occur in August, September and October.

◆

Manila, the capital of the Philippine Islands, is situated in latitude 14° 35′ North and in longitude 121° East of Greenwich. Observations have been made for many years at the Observatorie Meteorologico de Manila, and rainfall and other notes have been published for 17 years. From these we find the average temperature for the year to be 80° F., with April, May and June as the hottest months. December and January are the coolest, with an average of 77° F. The highest reading of the thermometer is 100° and the lowest recorded is 74°. The average relative humidity is 78%, with 85% in September and 70% in April. The average absolute humidity is 8.75 grains in a cubic foot. The average annual rainfall is 75.43 ins., of which more than 57% falls in July, August and September. The last is the most rainy month of the year, the rainfall averaging 15.01 ins.; and February is the dryest month, with 0.47 ins. The annual rainfall is marked by irregularity; as much as 120.98 ins. have fallen in one year; and only 35.65 ins. in another. In one September the rainfall was 61.43 ins., and in another September only 2 ins.

◆

THE HIGHEST METEOROLOGICAL STATION IN the world is on top of El Misti, with an elevation of 19,200 ft. above sea level; it is on an extinct volcano near the town of Arequipa, Peru. This station is one of a series of eight operated in connection with Harvard University near Arequipa, with the lowest only 55 ft. above sea level. and two others of 13,400 and 15,700 ft. elevation respectively. These establishments are the result of a bequest to Harvard, left by Mr. Uriah A. Boyden in 1887. The purpose of the bequest was to establish an observatory at such an elevation as to be as free as possible from the atmospheric influences effecting other stations. The highest station on El Misti is 3,500 ft. higher than the one on Mont Blanc. The instruments used include dry and wet bulb minimum and maximum thermometers, rain-gage, Richard baragraph, thermograph and hydrograph, also a meteorograph, designed to run for three months and record temperature, pressure, humidity and wind direction and velocity. These stations are regularly visited about once in a month, to wind up the clocks and change the record-sheets. Though the road is easy enough the trip to the top of El Misti is an exceedingly exhausting one to the uninitiated.

◆

THE ANNUAL RAINFALL AT RIVAS, near the Pacific coast of Nicaragua, says Dr. Earl Flint, of that town, was 123.43 ins. in 1897, or the greatest during the 18 years of his observations. Rivas is about 4 miles to the west of Lake Nicaragua and nearly on the line of the proposed Nicaragua Canal. Previous records by Dr. Flint, as reported by the engineers of the Nicaragua Canal Co., ranged from 30 to 90 ins. for the year. On the Atlantic side of Nicaragua, at Greytown, the annual rainfall in 1890 was 320.48 ins., with 274.85 ins. in the Deseado Valley, 12 miles inland.

◆

THE PHILIPPINE ISLANDS, as described by U. S. Consul O. F. Williams, of Manila, cover 150,000 sq. miles and have a population of 8,000,000 to 10,000,000. The Island of Luzon, on which Manila is situated, is larger than the States of New York and Massachusetts and has 5,000,000 population; the Island of Mindanao is nearly, if not quite, as large. In all, there about 2,000 islands in a land and sea area of 1,200 miles in latitude and 2,400 miles in longitude. Of the hemp exports of 1897, 914,055 tons, 41% went to the United States; more than 55% of the 1,582,904 tons of sugar, exported in the same year, came to this country. The average annual value of hemp and sugar exports to the United States, for the last ten years, was $8,926,372. There is but one railway in the islands, the 123 miles from Manila to Dagupin. This is a well built, single track line, with steel rails, stone or iron bridges and English locomotives making 45 miles per hour. The government assisted in the building of this railway by granting valuable land concessions and guaranteeing 8% on the stock for 99 years. The road pays more than 10% per annum. There are about 25,000 Europeans in the islands, of which 12,000 are at Manila. Trade is in the hands of English, Spanish and German houses.

THE MOST SERIOUS RAILWAY ACCIDENT of the week occurred June 28 at Vine Grove, on the Illinois Central R. R., about 37 miles from Louisville, Ky., and resulted in the death of two persons, the engine driver and fireman. The train was a coal special bound for Louisville, and was running at a good rate of speed, when, owing, it is stated, to the spreading of the rails, the locomotive and twelve cars left the track. The damage is estimated at $6,000.——A passenger train derailment on the Wabash R. R., near Burlington Junction, Mo., on June 29, resulted in the injury of some 20 persons, several of them seriously.——The explosion of a locomotive boiler on a suburban branch of the Erie R. R., at Essex Falls, N. J., on July 4, resulted in the injury of the engine crew. The cause of the explosion is not yet known.

◆

THE FAILURE OF A HIGHWAY BRIDGE crossing the Mohican River at Shelby, O., on July 4, precipitated about 1,000 people into the river 18 ft. below. Four persons were killed and nearly 100 injured. A public wedding was being celebrated on the bridge at the time of the accident.

◆

A TORNADO-LIKE STORM which occurred along the North Atlantic coast on July 4 resulted in a large amount of damage to property and the death of a number of people. At Hampton, N. H., four persons were killed by the destruction of a crowded skating rink and five were drowned by the capsizing of a yacht sailing off the beach. The foundering of the excursion steamer "Surf City" in the harbor at Beverly, Mass., resulted in the death of eight persons. Less serious accidents occurred to pleasure craft and sea shore resorts at other points on the New England coast.

◆

THE SINKING OF THE STEAMSHIP "LA BOURGOGNE" with the loss of 553 lives is reported in dispatches from Halifax, N. S., as we go to press. According to the latest reports, the "La Bourgogne" when about 60 miles south of Sable Island on her regular trip east, collided with the British steamer "Cromartyshire," at about 5 o'clock a. m., on July 4, and sunk within a few minutes after the collision. There were on board of the French liner at the time of the collision 75 first cabin, 123 second cabin and 285 steerage passengers, and a crew of 233 men, in all 716 persons. Of this number, 53 passengers and 110 of the crew escaped in boats and were picked up by the "Cromartyshire," which was herself badly damaged, and had to be towed into Halifax by the steamer "Grecian" of the Allan Line. According to the statement of the captain of the "Cromartyshire" the collision took place in a fog, and the French steamer was running at a high rate of speed when his ship struck the liner amidships, tearing a great rent in her plates. When the fog lifted, one-half hour later, the "La Bourgogne" had disappeared, having sunk, and only two boats and some life rafts, crowded with passengers from the ill-fated vessel, were visible. The sunken steamer was 7,400 tons gross tonnage, and was the third largest ship of the fine fleet of the Compagnie Generale Transatlantique. She was 508 ft. long, 52 ft. beam, and 38 ft. deep, and had engines of 9,000 I. HP. This was the third collision which the ship had had. On Jan. 4, 1890, she collided with the British steamer "Torridon" near the Scilly Islands, carrying away the stern of the British vessel and suffering slight injuries herself, and in February, 1896, she ran into and sunk the steamship "Ailsa," during a fog in the lower bay of New York harbor. There was no loss of life in these two earlier accidents. The "Cromartyshire," which suffered in this last collision, was a three-masted iron freight steamer of 1,554 tons gross tonnage, 249 ft. long and 32.8 ft. beam. All of the officers of the "La Bourgogne" were among the drowned, except the purser and three engineers.

◆

THE "WHALEBACK" STEAMER "Alexander McDougall," launched at Superior, Wis., on June 25, was designed by Mr. Albert C. Diericx, of the American Steel Barge Co. She is 430 ft. long over all, 414 ft. keel, 50 ft. beam and 27 ft. molded depth. There is a 5-ft. double bottom, with a water-ballast capacity of 2,000 tons and her displacement is nearly 10,000 tons, with a cargo capacity of 7,200 tons. She has quadruple expansion engines. The vessel has 13 hatches for loading, each 24 × 8 ft. in the clear and 24 ft. apart on centers; her coal capacity is 350 tons and she is fitted with two 90-ft. masts.

BUILDINGS AT THE OMAHA EXHIBITION.

In our issue of May 19 we briefly described the scope and purpose of the Trans-Mississippi & International Exhibition, now being held at Omaha, Neb., and also gave some particulars of the principal buildings. We now present views of four of the buildings, and from these and the particulars already given it will be evident that the exhibition has been planned upon the artistic basis so perfectly carried out in the design of the ever-memorable Columbian Exhibition at Chicago in 1893.

The U. S. Government Building, Fig. 1, is at the head of the "grand canal," and consists of a central portion and two wings. The former is 208 ft. long, 150 ft. deep and 58 ft. high to the top of the parapet above the cornice. The dome is surmounted by a figure of "Liberty," whose torch is 178 ft. above the ground. The wings are each 148 × 100 ft., and 44 ft. high. They are connected by colonnades with the Fine Arts Building and the Agricultural Building. The total frontage is 504 ft., and the floor space devoted to exhibits aggregates 50,000 sq. ft. This building was designed by the Supervising Architect of the U. S. Treasury Department.

The Manufactures Building, Fig. 2, is 400 ft. long and 40 ft. high to the main cornice. The main entrance, 24 ft. wide and 34 ft. high, is in a center pavilion 64 ft. long, and at each corner of the building is a pavilion 40 × 40 ft. The height to the top of the group of statuary over the main pavilion is 85 ft., while the height to the tops of the flat domes of the corner pavilions is 65 ft. The windows are 10 ft. wide and 24 ft. high, placed 16 ft. apart. The architect was John J. Humphrey, of Denver, Colo.

The Mining Building, Fig. 3, is treated in a somewhat more ornate style, and has a circular portico or main entrance 50 ft. in diameter, surmounted by a dome formed as a series of circular steps. The top of the dome is 75 ft. above the ground. This portico projects beyond the face of the building, and is flanked by open colonnades extending to the towers at the corners. The building was designed by S. S. Beman, of Chicago.

The Horticultural Building, Fig. 4, is 310 ft. × 130 ft., with a height of 160 ft. to the top of the central tower, or belfry, in which will be placed a set of chimes. The central portion of the building is octagonal in plan, formed by square towers with connecting curtain walls, and above this is a glass dome surmounted by a gallery accessible to the public. The main entrance is a Greek portico, and domed pavilions mark the corners of the building. The architect of the building was Charles F. Beindorf, of Omaha, Neb.

The exhibition was opened on June 1 by President McKinley at Washington, who pressed an electric button, starting the machinery and unfolding a flag on the Government Building. It will remain open until November.

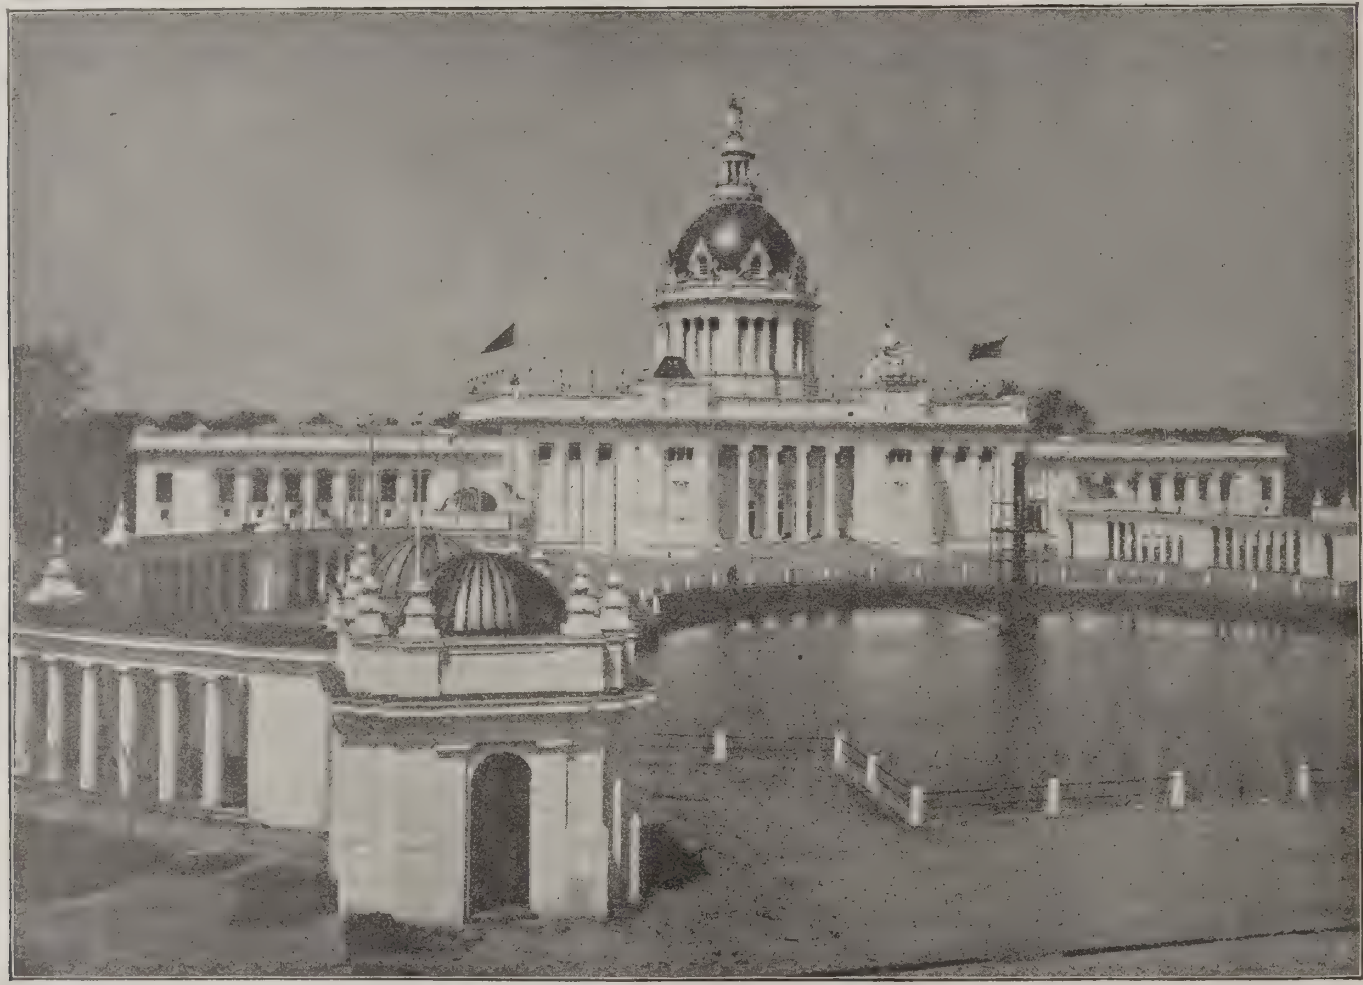

FIG. 1.—UNITED STATES GOVERNMENT BUILDING. TRANS-MISSISSIPPI AND INTERNATIONAL EXHIBITION.

THE NEW U. S. GOVERNMENT NEEDLE DAM AT LOUISA, KY., ON THE BIG SANDY RIVER.

(With double-page plate.)

General Features.

The new Poiree needle dam, which was opened for public use on Jan. 1, 1897, at Louisa, Ky., on the Big Sandy River, is a radical departure in many particulars from the dams of this type heretofore built in France and Belgium, where the Poiree system originated and has been most extensively used. First among its notable features probably is that it sustains a head of water which considerably exceeds that supported by any other dam of the trestle or wicket type yet constructed. Besides this, however, the construction and operation of the trestles, needles and raising and lowering machinery also embody new features never employed before, and finally it is stated that the cost of the dam was relatively smaller than that of previous Poiree dams, so far as is known. These facts alone are sufficient to make the new dam worthy of notice, but as we point out elsewhere in this issue, it also deserves attention as a representative example of the very high class of structures which the latest improvements of our inland rivers for navigation is calling upon engineers to design.

Through Mr. B. F. Thomas, M. Am. Soc. C. E., U. S. Assistant Engineer, who designed and constructed this dam, we have, therefore, secured a number of photographs of the completed work, which we supplement with the accompanying description and line drawings abstracted from the official report of the same officer published in the "Report of the Chief of Engineers" for 1897.

Conditions Governing Type of Dam.—The new dam is located near Louisa, Ky., just below the junction of the Levisa and Tug rivers, which unite to form the Big Sandy River, which in turn empties into the Ohio River about 26 miles north of the junction. The Levisa River is navigable by steamboats during a good part of the year for a distance of 100 miles, and the Tug River for a distance of 60 miles. Beyond these points push-boat navigation is possible throughout the year, except in periods of extreme low water, which are usually of short duration. Both streams carry a large amount of sand and debris, which would be very likely to form bars and snags in a permanent pool, such, for example, as would be caused by a fixed dam.

A more important reason why a movable dam seemed desirable was the nature of the commerce, which is very largely timber in rafts. There are times when rafting stages of the river are infrequent, and hundreds of rafts are awaiting sufficient water to reach the Ohio River. When the long-delayed rise comes, it is often of short duration and has to be taken advantage of at once. In such cases the delay necessary to pass the commerce through the lock of a fixed dam would very likely result in a failure to reach the markets along the Ohio and Mississippi rivers during an entire season. The same argument applied to the shipment of coal in barges, which seems likely to become a quite important portion of the traffic as soon as the neighboring coal fields are developed. There were various other reasons why a movable dam seemed preferable to a fixed dam, which was the type of structure originally contemplated, but they need not be detailed here.

Choice of System of Movable Dam.—A movable dam having been decided upon, the next step was to choose a system best adapted to the conditions. These conditions were briefly as follows: (1) An unprecedented head of water to be sustained; (2) sudden and unexpected rises in the stream; (3)

the great amount of sediment and drift carried; (4) the great difference in level between high and low water, and (5) the small low water discharge. The high lift was unfavorable to the use of needles; the sudden freshets were an argument against any form requiring much time for maneuvers; the drift and sediment, to any system having trestles; the height of high water and the high banks, to bridge dams; and the small discharge of the river, to wickets of the Chanoine type. The Chanoine wicket and the Poiree needle seemed upon study, however, to have the fewest disadvantages, and it was finally decided to build a needle dam, with a supplementary lock. The works as finally constructed (Fig. 1), therefore, consisted of (1) a lock on the right, or Virginia bank, 52 ft. wide and 255 ft. long over all; (2) a navigation pass next the lock 130 ft. long, having a depth of 13 ft. of water on its sill, and (3)) a weir 130 ft. long separated from the pass by a masonry pier 12 ft. wide and terminating in an abutment 17½ ft. wide on the left, or Kentucky bank. The weir has a depth of 7 ft. of water on its sill.

Lock.

The lock, which is of sandstone masonry, is 255 ft. in length, with a distance between quoins of 190 ft. and a clear width of 52 ft. The walls stand 21 ft. above the lower miter sill level. The lower miter sill is at an elevation of 9 ins. below the low water mark of 1883, and the upper miter sill is 2 ft. above the lower. The gates are of wood, and are of the miter pattern. The filling of the lock takes place through valves in the upper gates and the discharge through culverts in the side walls, which connect the lock chamber with the pool below. In constructing the lock the entire site was enclosed by a coffer-dam, inside of which the excavation and masonry work were carried on by ordinary well-known methods. The cost of the lock, including everything properly chargeable, was $120,372. The object of the lock is, of course, to pass the traffic during stages of low water when the dam is raised.

Construction of Movable Dam.

As already stated, the movable dam proper is divided by a pier into two parts, the navigation pass and the weir. The purpose of the pass, as its name indicates, is to accommodate the navigation during high water, while that of the weir is to pass the surplus water. In deciding upon the dimensions to be adopted, the pass, of course, had to present an opening long enough to be run safely by the rafts, tows, etc., of the kind that navigate the Big Sandy River, and deep enough so that its sill should not form an additional obstruction; that is, it had to be below the highest natural obstructions in the river. To satisfy the first condition it was thought that an opening of 130 ft. would be ample, while the depth would be sufficient if the sill were placed 1 ft. below the low water level of recent years. The conditions to be satisfied in dimensioning the weir were: (1) The area of discharge must be sufficient, when taken in connection with those of the pass and lock to permit the passage of discharges corresponding to all stages up to the level of the top of the pier and abutment, without causing a greater swell head than 0.5 ft.; (2) the discharge area of the weir should be sufficient to pass all discharges corresponding to stages up to that at which the natural river is navigable, without the removal of any needles from the pass. It was found that these conditions would be satisfied by placing the sill of the weir 6 ft. above that of the pass and making it 140 ft. long.

Substructure.—The dam is founded on sandstone, varying in depth below low water from 3 ft. at the lock wall to 24 ft. at the abutment. Upon this, after removing the overlying sand and gravel and the softer top parts of the ledge proper, was built the substructure of concrete and sandstone masonry. Figs. 2 and 3, transverse sections through the pass and weir respectively, show the construction of this substructure quite clearly. In the pass it is 22 ft. wide at the coping and in the weir 17 ft. wide, while the heights are, respectively, 12 ft. and 24 ft.

Trestles.—The pass is closed by 31 and the weir by 34 steel trestles, spaced 4 ft. apart c. to c., which terminate in eyes at the bottom and are connected to journal boxes by pins. The pass trestles, Fig. 4, are 15 ft. 2 ins. high, and weigh 1,140 lbs. each, and the weir trestles are 9 ft. 8 ins. high and weigh 920 lbs., and they have bases 9 ft. 10½ ins. and 6 ft. 5 ins. long, respectively. The other features of the trestle construction are shown by the drawings, Figs. 2, 3 and 4.

The trestles are rigidly connected by two independent constructions, and the maneuvering chain constitutes still a third connection. One of these connections is the bar which forms the upper support of the needles. This bar is hinged vertically to each trestle at the pool level so as to swing horizontally, and has its opposite end formed into a hook on its upstream side, which engages with a lip or projection on the next trestle. It is held in position by a crank-shaped rod which may be turned from the walkway by a wrench when it is desired to let the bar swing free. When in use the crank-shaped rod is held from turning by a latch, which is disconnected when the wrench is dropped over the head of the rod. The second means of connecting the trestles is the sheet-iron floor plates. Each floor plate is hinged to its trestle horizontally and spans the opening to the next trestle, to which it connects by means of hooks at two points. A latch moved by the foot holds each section in position.

In a frame bolted into the head of each trestle is a combined ratchet and chain wheel, over which a chain passes from one end of the pass to the other. There is also a similar chain for the weir. One end of each chain is fastened, in the case of the pass to the trestle nearest the pier, and, in the case of the weir, to the trestle nearest the abutment. The other ends of these chains are wound on chain crabs, located respectively on the lock wall and the pier. By means of a pawl dropping into the ratchet, the rolling of the chain wheel may be stopped, and when this occurs the trestle is attached to the chain and the winding of the crab will move it as desired. Fig. 5 shows the construction just described quite clearly, and a little further on its operation in raising and lowering the trestles will be described.

Needles.—The needles are of white pine and are 12 ins. in width. The pass needles are 14 ft. 3 ins. long, 8 ins. thick at the bottom, 4 ins. thick at the top, and weigh when wet 263 lbs. each, and the

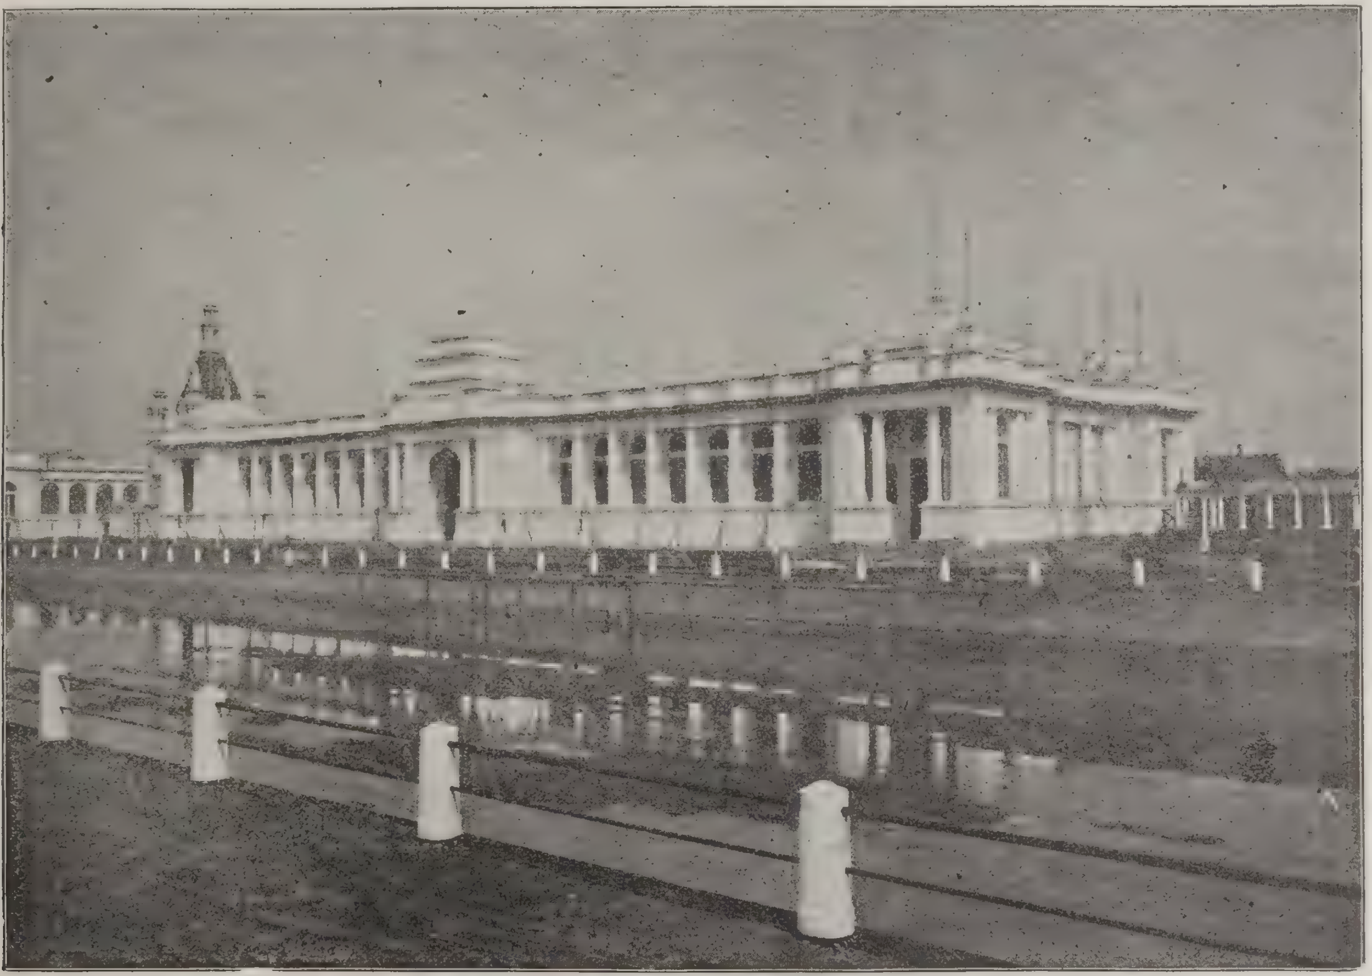

FIG. 2.—MANUFACTURES BUILDING. TRANS-MISSISSIPPI AND INTERNATIONAL EXHIBITION.

weir needles are 8 ft. 3 ins. long, 3½ ins. thick at the bottom, 2½ ins. at the top, and weigh about 80 lbs. All needles are banded at the top and bottom, the bands being countersunk, and carry iron handles and suitable attachments for connecting the chains to place and remove them. In the sides of the pass needles a shallow groove is cut which will hold a strip of rubber should it become desirable to restrict the leakage. The pass needles when not in use are stowed on a boat built for the purpose. This boat is provided with two overhead tracks on which run trolleys for lifting the needles from the piles and carrying them to the end of the boat when they are to be put in the dam and for piling them when they are to be stored.

Drift Boom.—The river, as already stated, carries a large quantity of drift which, if it were not deflected, would interfere with the operation of the dam and might even injure it seriously. To deflect this drift the drift boom has been provided. This boom consists of four parallel timbers rigidly bolted together and having rudders at intervals of 30 ft., and reaches from a point some distance above and on the opposite bank from the lock to the crib at the river wall of the lock, thus guiding all drift into the lock through which it is passed. The rudders on the boom are controlled by a wire wound on a capstan at the end, and by setting them at the proper angle the boom can be held out in the stream at any point required.

FIG. 3.—MINING BUILDING. TRANS-MISSISSIPPI AND INTERNATIONAL EXHIBITION.

Operation of Movable Dam.

From the description and illustrations just given the construction of the several parts of the Big Sandy River needle dam will be pretty clearly understood. A brief explanation will be sufficient to make its operation equally clear.

Raising the Trestles.—The raising of the trestles may be accomplished in two ways: (1) By a crab located as already stated, on the pier, for the pass trestles, and on the lock wall, for the weir trestles; (2) by the needle boat anchored above and raising the chain passed over a sheave and leading to the drum of the boat engine. Up to the present time the latter method has been but little employed owing to the lack of a suitable engine on the needle boat.

By the first method the chain is wound in by the crab and is stowed away in a suitable recess in the masonry. As the chain is wound in it brings up the first trestle and starts others. When the first trestle is nearly upright the attendant standing on the masonry lifts the end of the floor section a few inches which depresses one end of the pawl and raises the opposite end out of the ratchet in the chain wheel, as shown by Fig. 5. This severs the former rigid connection between the trestle and the chain, and the attendant can handle the trestle at will without the crabman stopping the winding in of the chain. He, therefore, hooks the floor section into place and fastens it with the foot latch, and then, standing on the bridge thus formed, swings the connecting bar into place and locks it by a turn of the crank bar. By this time the floor of the second trestle comes within easy reach, and the attendant proceeds to lock this trestle just as he previously did with the first. A repetition of this process raises the entire number of trestles, the work for either the pass or the weir consuming about 40 minutes.

It will be observed that, by winding in the length of chain at which the trestles are spaced, each trestle is brought up. After the first one, which has a sufficient length of chain to reach from the top to the bottom of the masonry, and thence to the head of the trestle when down, the length is generally 4 ft.; that is, the trestles themselves are 4 ft. between centers, and, by allowing 8 ft. of chain to each it is only necessary to wind in 4 ft. of this to bring the trestles properly into position. When the last trestle has been raised, a rolling bridge is drawn out from a recess in the masonry and connected with it, and thus a foot bridge is completed from one part of the masonry to the other.

Lowering the Trestles.—In lowering the trestles the attendant stands on the foot bridge and first unhooks the rolling bridge and pushes it back into its recess. He then disconnects the escape bar of the last trestle and throws it around against its trestle and then unhooks the floor section, which falls upon the chain and rests there. The crabman then slacks the chain, allowing the trestle to fall. When the chain has been run out about 4 ft. the attendant throws the pawl of the standing trestle into its ratchet and thus the descending restle is stopped. The escape bar and floor section of this trestle are then relieved and it begins to fall as the chain is paid out, until when the chain has run out about 4 ft. the operation of throwing the pawl into the ratchet of the next standing trestle is repeated. A repetition of these maneuvers brings all the trestles to their beds with their floor sections resting on top of them. The time required for lowering either pass or weir is about 40 minutes.

Placing the Needles.—Two methods have been employed for placing the needles in the dam.

(1) The pass needles, as previously stated, are stored on a special boat (Fig. 6), which is anchored so that its bow is only a few feet upstream from the trestles, with their heads or tops all in one direction toward the dam. A trolley track runs over the pile of needles on each side of the boat, and the trolleys have sheaves over which pass chains having hooks at their free ends. At about the center of weight of each needle is a ring. By placing the chain hook in this ring and pulling down on the free end of the chain the needle is raised from the pile. Near the hook is a catch or claw on the chain, the purpose of which is to hold the bight of that part of the chain pulled down in raising the needle. Thus the needle, after being raised, remains suspended, and by pushing it the trolley rolls along the track overhead and carries it out to the bow of the boat. When the needle is brought to the end of the trolley track its head projects over the foot bridge, where it is grasped by the attendant and placed on the support bar alongside the last needle put in.' The trolley track projects over the hull of the boat several feet, so that when the head of the needle is in its proper place on the trestles the butt or foot is just at the bow. When all is ready a quick jerk on the free end of the trolley chain releases it from the claw and the weight of the needle pulls the chain over the sheave. When the needle strikes the water the current carries it against the sill, the force of the

blow being lessened by the men holding the free end of the chain, thus allowing it to come to place easily. As soon as the strain is off the chain, the hook drops out of the ring. A stage-plank projects about 15 ft. from one side of the boat parallel with the dam, so that it is possible to place about 30 ft. of dam by allowing the needles to float out to position without moving the boat.

(2) In the second method the needles are left in the river instead of being stored on the boat, and are lifted from the water by a light derrick on the needle boat (Fig. 6), and placed vertically, either on swinging shelves suspended on the upstream side of the trestles, or on a suitably constructed frame resting on the sill at the bottom. In placing the needles every fourth one is put in its proper place against the sill instead of on these shelves or frames. These act as guides to the others when they are let into the water, and the shelves or frames themselves prevent the needles from being carried downstream by the current (Fig. 7). After all the needles have been placed on the resting planks or frames they are dropped into the water as rapidly as practicable and the whole dam is in before the head has appreciably increased. The shelves and frames are then loosened and taken to the bank.

The weir needles are placed before those of the pass, and while there is still some water on the weir sill. This is easily and rapidly done by men standing on the masonry above the sill and taking the needles from a light boat or directly out of the river. The principal advantages of this method is that the closing of the weir increases the current through the pass and tends to scour out any deposit on the trestles which are not raised until after the weir is closed.

Removing the Needles.—When a rise approaches, the wickets in the lock gates are opened, and when they fail to keep the pool down to its normal level, alternate needles in the dam are "repoussed;" that is, the heads of alternate needles are pushed upstream and struts or sticks 12 ins. to 15 ins. long are placed between them and the support bars (Fig. 8). This permits the escape of a great quantity of water. When this fails to keep the pool down, the weir needles thus standing out may be removed entirely, or, if indications point to a considerable rise, all the weir needles may be removed. A continuation of the rise may finally necessitate the removal of all the needles standing out in the pass, or even the whole of the pass.

This last process is conducted in the following manner: Near the top of each needle is a countersunk handle for use only in removing the needle. A chain much longer than the length of the dam is passed along the upstream side of the needles and connected by hooks with these handles. There is considerable length of slack chain between each pair of handles. The end of the chain is fastened to a long line leading to the engine on the needle boat, which is anchored well upstream, or to a crab on the lock wall or on shore. By starting the engine or crab the first needle is pulled away from its support at the top, and when it has traveled the length of the slack chain leading to the next, the second is started, and so on. This maneuver is very rapid, the time required being simply that which is necessary to wind the rope on the drum of the engine.

Results of Operation.—Considerable interest is attached to the results obtained in the actual operation of this dam, and in a paper read before the American Society of Civil Engineers on March 16, 1898, by Mr. B. F. Thomas, the following information is given regarding this matter:

> The dam has, at this writing, been in operation nearly one year. The early part of the present season was one of violent thunder storms and sudden freshets, which brought much driftwood into the river. About the last of July a drouth set in which was of unusual duration. The discharge of the river became reduced to less than 50 cu. ft. per second. The pool has remained full at all times, except when drawn off to assist small craft below or to perform necessary work about the lock and dam. The greatest head so far attained was 12 ft. 2¼ ins., and the leakage through the pass was only 5.19 cu. ft. per second, and that of the weir too small to take into account, being but one gallon in 38 seconds.
>
> No trouble has been experienced with the pass; the needles have been removed and placed, and the trestles have been lowered, each time without difficulty of any kind. In raising the trestles the chain was broken on two or three occasions, caused by heavy deposits of sand on the floors which form the foot-bridge when up. With one exception this has occurred only on the trestles which lie in the pier recess. It has been found impracticable to leave the lock gates open on account of the increase of this deposit, due to the greater discharge section and consequent reduction in current velocity. By closing the lock and erecting the weir some time before the water level reaches its masonry crest, considerable scour takes place through the pass and no further trouble from this deposit is anticipated. In the pier recess the removal of the floor sections, before lowering the trestles, will prevent a deposit of sufficient weight to break the chain. On the weir there has been a little trouble with drift, but it was of slight consequence. The raising of the trestles and the removal and placing of the needles is done with the greatest facility. What difficulty there has been has arisen from permitting the trestles to stand after the removal of the needles in the drift-laden torrent caused by the release of so much water. The larger drift is held back by the boom, but small pieces, brush, etc., are drawn under the boom by the increased current, caused by opening the dam, and some of this lodges against the standing trestles. With trestles of wider span and by lowering the trestles simultaneously with the needles, most, if not all, of this difficulty can be obviated. It has not been practicable to do this, however, owing to lack of bank protection below the abutment. The opening of the needles from the abutment end of the weir causes great scour for some distance below and endangers the paving, so that it has been considered advisable to make the first openings in the dam at the pier end. Thus it was necessary for the trestles to stand until all the needles were removed, when the lowering could begin at the abutment. Even with this drawback the total delay caused by drifts has not exceeded two hours in the whole year, and but one trestle has been bent and only slightly.
>
> On account of the great quantity of drift running in this river it was originally proposed to use wickets on the weir, raised without the use of a foot-bridge and lowered by a tripping bar; thus no trouble would be encountered by drift lodging against the trestles as now occurs on wicket dams operated from trestles. This arrangement, in the light of experience, would have been preferable, so far as disposing of the drift is concerned, but the leakage would have been more than the entire low-water discharge of the river, unless improvements could have been made over those now in use. Either method has its objections and its advantages and neither is wholly suited to a weir through which drift must pass. The only serious objection, outside of the lodging of drift on the trestles, is the difficulty of replacing the wide needles

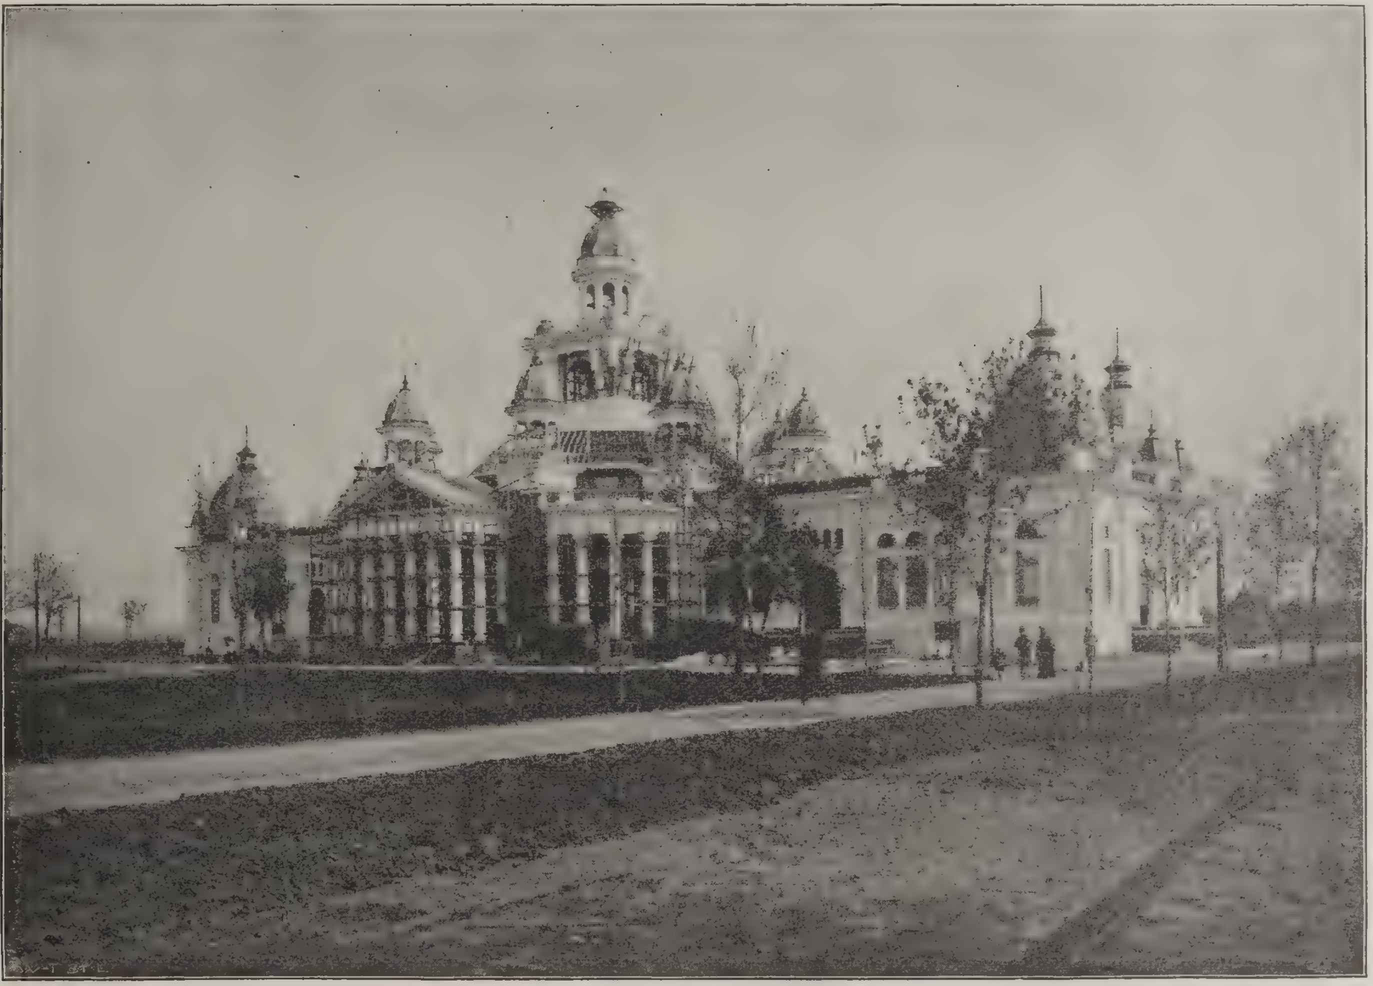

FIG. 4.—HORTICULTURAL BUILDING. TRANS-MISSISSIPPI AND INTERNATIONAL EXHIBITION.

under the full head after they have once been removed to pass a moderate rise, but even this is not impossible and is rarely necessary. The width of weir needles can be advantageously reduced without seriously increasing the leakage and thus assist materially in this contingency.

In addition to the leakage wickets would be objectionable on this weir because they could never be put on the swing for fear of drift-wood lodging against the horses and thus complicating the maneuvers. Thus, pool regulation could not be effected in small rises with the certainty that it can by repoussing needles; but they have the advantage that they can be raised against the full head of water at any time desired, and thus prevent too great a lowering of the pool in passing small freshets. The author believes that the construction could be so altered as greatly to decrease the leakage and thus to a considerable extent eliminate this objection. Considering the untried methods necessary in this dam, it may be said that the maneuvers have all been fairly satisfactory so far. The dam has been operated in one or two instances under especially difficult conditions, and it is safe to predict success under all ordinary circumstances which may occur. A rapidly rising river, filled with drift arriving at night in snow or rain, might complicate matters considerably, and change an apparent success into a certain failure, without warning. All precautions possible, except the construction of telephone lines owned and operated by the government, have been taken to provide against surprise, and results are now to be awaited and difficulties met with courage and intelligence.

The experience so far gained with this dam indicates that its operation will be at least as speedy, easy and safe as is that of the wicket dams on the Great Kanawha or of the needle dams of the old type in Europe, while this dam is much less wasteful of water than any of these, which is an important item in this and many other streams.

Cost.—The total cost of the Big Sandy River needle dam and its auxiliary constructions was $349,155, divided as follows:

Lock	$120,372
Movable dam	76,251
Approaches, protection work, etc.	35,553
Fixed dam and abutment	26,734
Miscellaneous	29,263
Engineering, superintendence, etc.	40,440
Office expenses at Cincinnati	20,542
Total	$349,155

This total would have been considerably less if the original design had not been for a structure differing considerably from the one actually built, which acted in various ways to increase the expense. It was estimated by the engineers that under favorable conditions the dam could be built for $198,152.

A RECENT EXAMPLE OF AUTOMATIC, INTERLOCKING MACHINERY FOR OPERATING A SWING BRIDGE.

By Charles H. Wright.*

There is no more interesting work falling to the lot of the bridge engineer than the designing of the machinery for a large draw span, and there is, perhaps, no branch of his work in which such marked advance has been made in the last few years. It is no longer sufficient to provide means for rotating the span, and for supporting the ends, when the span is closed; the break in the rails at the ends of the span must be bridged over, a continuous bearing surface provided for the car wheels, and the rails clamped rigidly in line. Some form of latch must be used to assist in bringing the span to rest at the end of the return swing, and to bring the end locks into line. Danger signals must also be thrown at the ends of the bridge and at points several hundred feet distant out on the track. The machinery for performing all these movements must be under the full control of the operator in the engine-house, and many of the movements must be automatic in their action. A regular order must be followed, in performing the several operations, and the levers controlling them must be so interlocked that any variation from the fixed order of operation is impossible. Indicators attached at various points must show the exact stage of each operation at any time, as when the end lifts are fully drawn, partly driven, or with ends lifted, etc. Often a small electric light plant is installed on the bridge, and if steam power is used the little remaining space left in the engine house is taken up by the tanks and pumping machinery necessary for supplying the boilers, etc.

The interlocking and automatic devices used on a long span recently constructed by the Edge Moor Bridge Works, are shown in Figs. 1 and 2. There are three sets of friction clutches operated by the levers at A, B and C. At Y there is a set of equalizing gears for distributing the load equally to the two pinions. Fig. 1 shows the bridge closed, with all the levers locked, with the exception of lever A, which can be thrown to the right. The action briefly described is as follows:

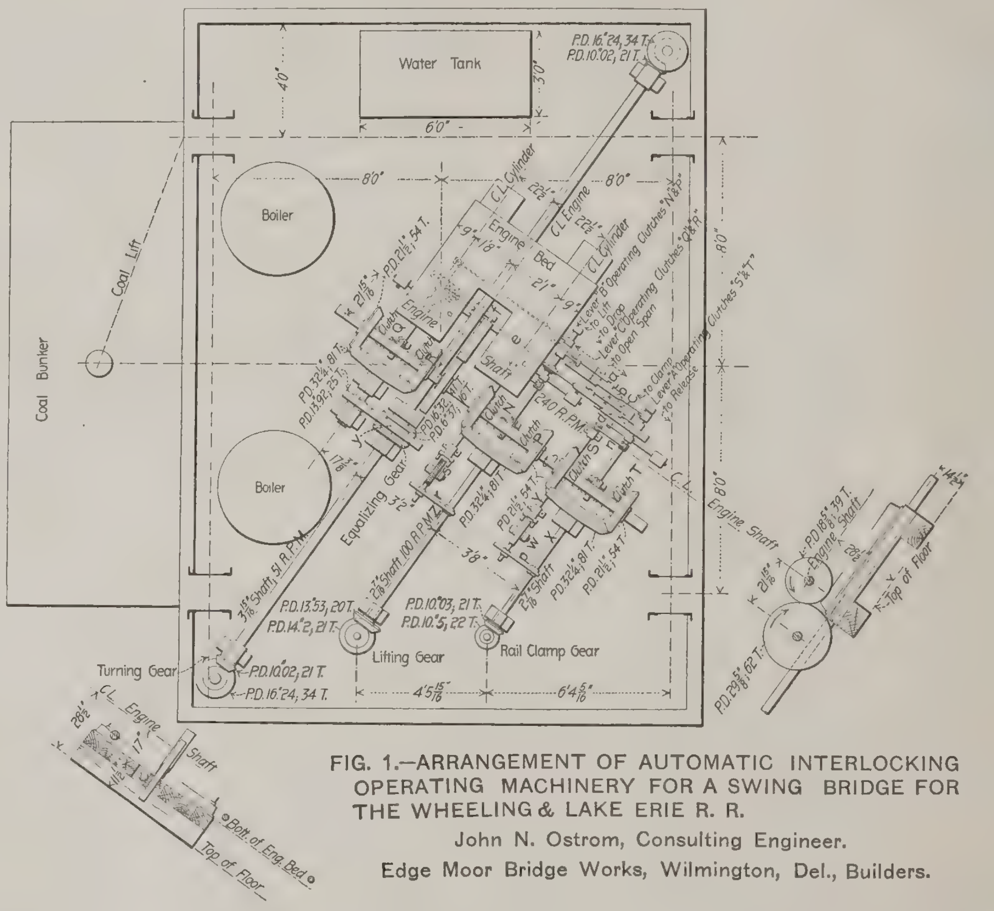

FIG. 1.—ARRANGEMENT OF AUTOMATIC INTERLOCKING OPERATING MACHINERY FOR A SWING BRIDGE FOR THE WHEELING & LAKE ERIE R. R.

John N. Ostrom, Consulting Engineer.

Edge Moor Bridge Works, Wilmington, Del., Builders.

Assume the draw closed, the ends lifted and the signals showing a clear track. If the bridge is now to be opened the first operation will be to throw the signals and draw the rail clamps. By throwing lever A, which controls the clutches S and T, to the right, clutch T is engaged and drives the line of machinery, which releases the danger singals at the end of the span, and at points 400 ft. distant. These signals are thrown by springs or counterweights, which are released by the withdrawing of an arm which upon the return movement revolves the vertical shaft to which the signals are attached and compresses the springs. At the same time that the signals are thrown to danger the rail clamps are drawn back by a system of gears and levers, controlled by the same shaft which operates the signals.

When the lever A was thrown to the right it pulled the lock bar, a, to a position where it unlocked the lever B, which operates the end lifts. The bar b, however, still locks this lever. The lever C is also locked, so that the turning machinery cannot be moved in either direction. After shaft X has revolved a certain time, sufficient to draw the rail clamps, the chain gear p has turned the worm wheel w until the projection shown on the right-hand side of the wheel strikes the arm on the fork, which is attached to shaft Y, and by revolving this shaft throws the rocker n and brings the lever A to a vertical position again, which frees clutch T, and stops this portion of the machinery. As the lever A moves back to the vertical position it brings the notch in lock bar b opposite the lug on lever B, and thus releases this lever. Lever B can now be thrown to the right, but is still locked to the left. If B is now thrown to the right, clutch P is engaged and the end lifts are drawn. This motion of B throws the lock bars c and d, which lock A, and also throws e and f, f being thrown so as to unlock lever c, while the bar e still locks it. Lever A is now locked in one direction by the bar c, and in the other by the worm wheel and rocker n. Lever C is also still locked. When the shift Z has revolved a sufficient time to draw the end lifts, the chain gearing and the worm wheels (similar to the arrangement on shaft X) throw the clutch P out of gear and brings the lever B to a vertical position again. As B moves to the vertical position it throws the bar e, which unlocks lever C. This lever can now be thrown in either direction for turning the draw.

Lever A is meanwhile locked in both directions and B in one. In closing the draw the operation just described is reversed. There are indicators which show the progress of the different operations.

The interlocking and automatic cut-off machinery was designed by Mr. Chas. H. Wright, Chief Draftsman of the Edge Moor Bridge Works, and the Moore & White Co., of Philadelphia, who manufactured this part of the machinery. It has worked perfectly.

Fuller descriptions of parts of this bridge will be found in the work on "Draw Spans" by Mr. Wright, now in press.

* * *

RECENT RESEARCHES IN TERRESTRIAL MAGNETISM.

The obscure subject of terrestrial magnetism and the cause of the remarkable vagaries of the magnetic needle which occur, have been for some time under investigation by French and Russian scientists in connection with a large area in Central Russia. Recent press dispatches give some of the results of the experiments made on the country between Moscow and Kharkov, two cities 850 miles apart. It was found that the greatest aberration of the magnetic needle occurred in the Province of Kursk. At a station in the north of the Province the needle was deflected 20°, and at a place 150 miles to the southeast of the first point it was deflected 96°. At the latter station the needle pointed practically East and West, instead of North and South. The meager accounts so far received do not permit an explanation of this remarkable deflection, nor do they give any geological or other data upon which any reasonable explanation can be offered.

But, in a late paper presented to the Franklin Institute, Mr. Benjamin Smith Lyman, a mining engineer and geologist of long experience, notes a case of compass variation in Pennsylvania that seems to show some relation between magnetic and geological phenomena, in this connection. In 1883, Mr. Rudolph Hering, M. Am. Soc. C. E., made for the Water Department of Philadelphia a topographical survey of the Perkiomen Creek and the surrounding region, in Bucks and Montgomery counties. At the same time a magnetic map was made of this section, and curves of equal declination were drawn for every tenth of a degree. These curves were remarkable in their tracery; showing a fairly regular northeastward tendency or bend on an axial line which in itself bent the aggregate of lines of equal declination appearing somewhat like folds over some central object. The lines were so regular in their irregularity, and so much at variance with the simple straight lines of previous less detailed maps, that, in the absence of any obvious topographical or other known reason for their being, they were doubted by some and ascribed to mistaken observations or to lack of sufficiently accurate data.

---

*Chief of Drafting Department, Edge Moor Bridge Works, Wilmington, Del.

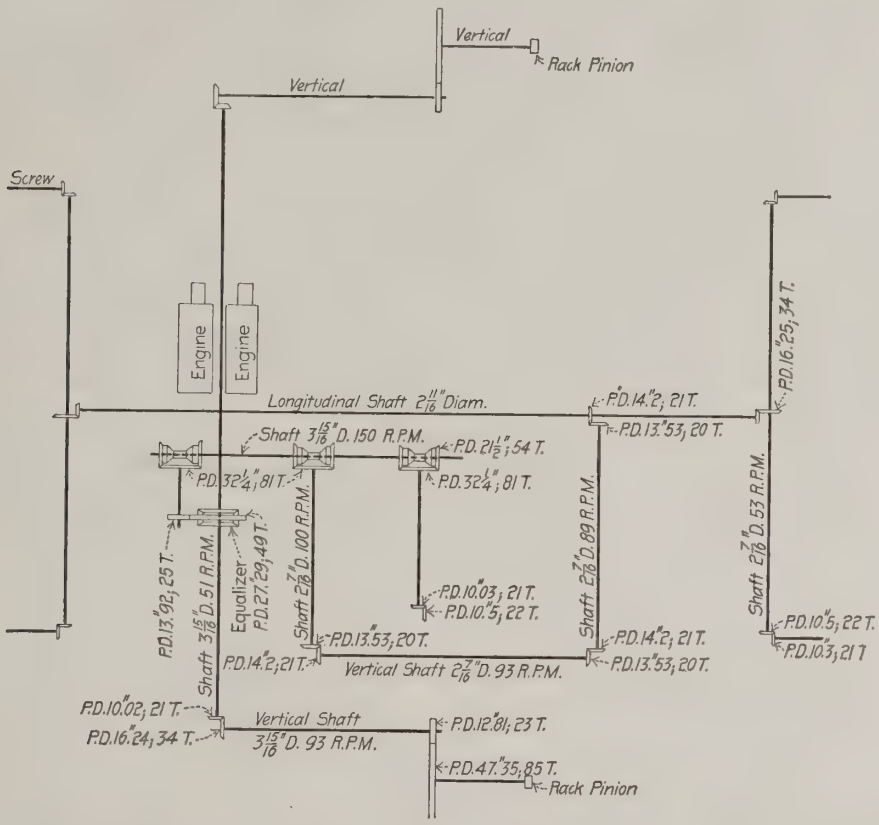

FIG. 2.—DIAGRAM SHOWING SIZES OF SHAFTING AND GEARING LEADING FROM ENGINE TO POINTS WHERE POWER IS USED.

But in 1887 a geological survey of these two counties was commenced, and a geological map was finally published, in 1893, giving the direction and amount of the dip at some thousands of points. This geological map, made without the least reference to the earlier magnetic map, beautifully confirmed the first, and by underground geology vindicated the general correctness of the observations made upon the magnetic deflection. The axis of the bend in the magnetic curves is itself greatly bent, almost at a right angle; and the geological survey has proved beyond a question the existence of an enormous fault of about 14,000 ft., lying almost exactly on this magnetic axis. The topography of the country shows no strongly marked ridge following the axis of the magnetic curves, and the long, rather high ridges run in other directions. Further, the form of the outcropping rock beds, sedimentary or igneous, does not correspond in any degree with the magnetic curves. Mr. Lyman does not believe that these curves could have been produced by any known deposits of iron ore or trap in these countries, whether they were strongly or weakly magnetic; and he adds that deposits of iron ore seldom affect the most delicate magnetic needle at a distance of more than a few hundred feet.

It is clear to him that the remarkable magnetic peculiarity observed must be closely related to the equally remarkable and completely corresponding geological structure; and this theory seems to be confirmed by the two thoroughly independent pieces of work noted. Perhaps some light is here thrown upon this obscure subject; for while the nature of the relation is not easily determined, it seems certain that the internal structure of the earth's crust has an important influence upon terrestrial magnetism. As Mr. Lyman remarks, some authorities explain this magnetism and its changes by solar influences alone; no longer considered as exerted by the direct action of the sun as a magnet, but by the heating of the atmosphere and of the earth's crust by the sun. The present experience, however, seems to point to more strictly terrestrial processes as the true cause, and to suggest that the solar influences may partly, at least, be exerted through the attraction of gravitation as well as through heat.

The author thus offers the following explanation: The enormous and locally unequal strains produced by the contraction of the earth's crust in cooling would be particularly liable to be affected by the presence of a deep fault or sharp anticlinal, both present in this case. These lines would indicate a yielding of the crust, and the existence of points where the strain has been to some extent relieved. This condition is here further proven by the recent occurrence of earthquakes along the New Jersey end of this very fault line, showing that the resistance of the crust is less, and the remaining strain must likewise be less. On such a comparatively weak and yielding line the rock beds, in readjusting themselves, even without any violent earthquake, must occasion not only a certain amount of strain, but also of friction and heat, and the latter may give rise to electrical currents.

A decided magnetic effect has been found to accompany, and sometimes to precede, earthquakes; and the attraction of the sun and moon may cause electrical currents by occasioning certain strains and readjustment in the earth's crust. A temporary local variation in temperature may follow the breaking or arching of rock beds, and set up electrical earth currents. Hence Mr. Lyman concludes that terrestrial magnetism may not only arise from the action of the sun's heat on the air and crust of the earth, but also from the internal movement of the crust and the tidal effect of the sun and moon upon the air, the ocean and the earth. This is a subject well worth following out, and magnetic investigation should accompany or follow the geological survey of underground conditions. In the Pennsylvania case the maximum declination, or magnetic variation, was not quite 7°. If the peculiar curves noted in this case were either occasioned by, or in some way related to, the fault line of 14,000 ft., which so closely follows the axial line of the magnetic curve, what should be the underground conditions which accompany the enormous deflections reported from Russia? If there is any fixed relation between terrestrial magnetism and geological formation, as the Pennsylvania surveys would seem to prove, the Russian case should present exceptional opportunities for further and conclusive investigation in this field. Mr. G. R. Putnam has lately been investigating magnetic disturbances on St. George Island, in Bering Sea, and reports them practically as follows in the "Journal of Terrestrial Magnetism":

"The Pribilof Islands, in the Bering Sea, and of which St. George is the second in size in the group, are entirely volcanic in origin. The Island of St. George is about 12 miles long by 5 miles wide, and its surface is covered with lava rock and scoria, with a heavy growth of grass around the borders. During the work of the U. S. Coast and Geodetic Survey parties on this and the neighboring island of St. Paul, regular magnetic observations were made at a base station, and the declination was observed at 24 scattered points on the eastern two-thirds of the island. These declinations showed a range from 5° 14′ East of North, to 20° .03′ East. Another station showed a declination of 5° 54′; while at three stations within one-quarter mile, and north northeast and southeast of the summit where the first was taken, the declinations were 14° 55′, 15° 38′ and 15° 27′. The variations appear to be chiefly due to the magnetic properties of the local surface materials. Small pieces of the rock or scoria would deflect the needle ¼°; and around a bank of red scoria the declination varied 3° in 60 ft."

◆

TRIAL OF SELF-PROPELLING CABS IN PARIS.

A trial of self-propelling cabs has lately taken place in Paris, including three electric and one petroleum motor. One of the first named type was really a double Victoria, says "The Engineer" in reporting the trial, entered by Bouhey & Co. It weighed 30 cwt. and ran with 60 cells weighing 32 lbs. each, developing 8 HP. It met with much trouble on the steeper Paris grades; the pneumatic tires gave way under its weight, but it finally succeeded in finishing the 37-mile course by giving the accumulators a 20-minute rest.

The course selected included one-third of bad road and steep gradients, one-third of heavy traffic streets and one-third of good roads. Nearly all the cabs proved that they were capable of making 37 miles, under the above conditions, daily for nine consecutive days. In an endurance test for the accumulator capacity the Jeantaud hansom made 53.6 miles; the Krieger cabs made from 56 to 62 miles, and the Jenatzy cab made 65 miles. On a descent of 8% most of the cabs stopped in about one dozen yards under the brakes.

In commenting on the trial "The Engineer" says that the test proved that electricity was the most suitable, cheapest and most convenient power for this type of service. But it also proved that something must be done before these cabs can be relied upon. As yet there is much tinkering on the road, and the ordinary driver cannot be relied upon to do this. With a few exceptions the vehicles tested made their daily runs at from 7.4 to 9.3 miles per hour, and some performed this work without the slightest attention. With others, however, stops had to be made for screwing up the brushes and fixing parts that had become loose or disarranged. In a Krieger cab the engineer spent 20 minutes in overhauling the cab to find why the current was interrupted, and finally discovered the fault in one of the accumulator connections. If an expert spent this time in finding a defect what could be expected of an ordinary driver? The mechanism must be made stronger and simpler and more reliable before the electric cab can be depended upon.

As to the pneumatic tires, in hard daily use these last about six months. The first cost of an electric cab is heavy; but in Paris the cost of electric power is 6 cts. per kilo-watt, and that of petroleum spirit is 11 cts. per liter, and as a consequence the electric vehicle is more economical in the end.

SUBSCRIPTION RATES: United States, Canada and Mexico, One Year, $5.00; 6 *months,* $2.50; 2 *months,* $1.00. *To all other countries in the Postal Union: Regular Edition, One Year,* $7.60 (31 *shillings*); *Thin Paper Edition, One Year,* $6.31 (26 *shillings*). *SINGLE COPIES of any number in current year,* 15 *cents.*

Mailing addresses may be changed at will by sending both old and new address. The number on the address label of each paper indicates when subscription expires, the last figure indicating the year and the one or two preceding figures the week of that year; for instance, the number 328 *means that subscription is paid to the* 32d *week (that is the issue of Aug.* 11) *of the year* 1898; *the change of these figures is the only receipt sent, unless by special request.*

ADVERTISING RATES: 20 *cents per line. Want notices, special rates, see page* 18. *Rates for standing advertisements sent on request. Changes in standing advertisements must be received by Monday afternoon; new advertisements, Tuesday afternoon; transient advertisements by Wednesday noon.*

The complete destruction of the Spanish fleet of armored cruisers and torpedo boat destroyers off the coast of Santiago, Cuba, on Sunday, July 3, by the United States fleet under Commodore Sampson, is an achievement of American arms, and we believe we may truly add of American engineering, unparalleled in modern naval history. The four armored cruisers sunk were among the finest naval vessels afloat. They had heavy armor belts of Harveyized nickel steel, guns and armament almost equal in power to those of our own battleships, and engines which should have enabled them to outrun any United States vessel afloat except the "Columbia" or "Minneapolis." Yet in the naval battle which followed the attempted escape from Santiago Bay, the Spanish vessels were unable to outrun the American; they were pierced by shot and shell until their crews could no longer fight them, and, most astonishing of all, their guns inflicted hardly a single injury upon the vessels of the attacking fleet.

When the United States victory at Manila was proclaimed, unfriendly European critics were not slow to say that the Spanish ships in that action were mere old tubs, unfit for fighting. We showed in our issue of May 12 that while our ships at Manila were unquestionably better vessels, the armament of the Spanish vessels was not so very much inferior to ours, and neither fleet had armor that could be expected to prove effective in keeping out anything but the smallest projectiles.

Our foreign critics have now to reflect on the fact that in another naval battle, nine weeks after the battle of Manila, four of the best vessels afloat in the Spanish or any navy are sunk or driven ashore in a sinking condition or on fire, with hundreds of their crews killed. On the American side one man killed marks the total of casualties.

◆

Our esteemed contemporary, "The Engineer," of London, in its issue of June 3 appeared to think that the entry of Cervera's fleet into Santiago was a great piece of generalship on the part of its commander. We remarked a fortnight ago that this was the place of all others where the American commanders wanted him to go, and we presume "The Engineer" understands by this time the reasons for our assertion.

In this connection we are interested to note that in its June 24 issue our contemporary declares that "the war is rapidly reaching a ludicrous stage. Every natural item that can be invented has already been invented by the American Press."

We acknowledge that the great inventive powers usually accredited to Americans are shared by our newspaper reporters; but they have not had time to do much inventing this week. Recent events may also seem ludicrous to "The Engineer," but we very much doubt whether the Spanish people will find anything in them of a ludicrous nature. Nor is there anything ludicrous to Americans in the condition of a defeated foe. For Spain's unfortunate soldiers and sailors and for her common people, Americans have genuine sympathy; and they deeply regret that in order to put an end to a century old system of misgovernment and oppression this government has been forced to add to the sum of their sufferings.

◆

At the outbreak of our present war with Spain the fleet of torpedo boat destroyers belonging to the latter nation was the occasion of much uneasiness on this side of the Atlantic, not only among the people at large but in our navy itself. We had no vessels at all of this class, while those of Spain were of the latest English models and build, thoroughly equipped, of great speed, and credited with a capacity for untold mischief to our slow and heavy ships of war as soon as fate should bring them together. These fast destroyers, rather than the cruisers of Cervera's fleet, were supposed to be the dangerous element in the attack upon our battleship "Oregon," which was at one time deemed possible; and even after Cervera's fleet took refuge in the Bay of Santiago there was always a chance that these fleet little war engines would dash out and make trouble for the United States vessels outside. Naval authorities of all nations anxiously awaited the results of the battle between destroyers and battleships, neither of which had been fairly tested in modern naval warfare, and the general impression among the Continental powers was that it would be the United States that would be badly hurt.

The result of two months' experience with torpedo boats and "destroyers"—as handled by Spaniards—is almost ridiculous. At Manila some torpedo boats made a brave and reckless dash at the ships of Admiral Dewey, but they were met by such a hail of well-directed rapid-fire projectiles that they were riddled and had to turn and run for the beach. At San Juan, lately, a torpedo boat destroyer, one of the finest afloat, came out and attacked a converted Atlantic liner, but she was forced to turn back in a sinking condition, with part of her crew killed, before she could get near enough to her opponent to discharge a torpedo.

Later still, when Cervera's fleet made the desperate dash out of Santiago Harbor, two of the destroyers ran toward the "Brooklyn" with the apparent intention of torpedoing her. Before they could carry out their purpose, however, they were both attacked and sunk by the "Gloucester," a converted pleasure yacht formerly known as the "Corsair" and owned by Mr. J. Pierpont Morgan. Admiral Cervera is said to have given way to tears when a few minutes later he found himself a prisoner of war on this same "Gloucester," and it is small wonder if he did. His four very powerful and heavily armored warships had all been sunk without damage to a single ship of the enemy and with only one man killed on the entire American fleet; and he found himself a prisoner on board the very vessel, a mere pleasure yacht, that had destroyed two of his redoubtable "destroyers."

While a different story would probably follow an attack of torpedo boat destroyers when manned by English or American sailors and with their movements directed by officers of either of these nations, there are some lessons to be learned from the fate of the Spanish vessels of this class. The first is that with rapid-fire batteries properly handled by men who can shoot, and hit what they shoot at, there is every probability that a destroyer can never come near enough to the enemy to inflict any damage with her torpedoes. The destroyer is a fast but very vulnerable craft, but the projectiles of modern guns are far faster, and a very few of them of moderate caliber are capable of putting her out of action. Many naval authorities have long agreed that the proper function of torpedo vessels is in night attacks; but the recent perfection of naval searchlights has greatly lessened the chances of torpedo boat success even in the night time.

It will not be strange if experience with torpedo vessels in the present war should lead to the naval powers assigning them less prominence in their armaments. At the same time it must be fairly said that the lesson of the war which is far more strongly emphasized is that neither personal bravery nor the possession of powerful vessels can compensate for the lack of mechanical skill, good marksmanship and able generals.

◆

The conclusions of the special committee report on "Tests for Constant Volume of Portland Cement" that was presented at the annual meeting of the Association of German Portland Cement Manufacturers in February, 1898, which is quite fully reported elsewhere in this issue, should, we think, be accepted with some reservation by American engineers. The committee, it will be noted, asserts bluntly that in its opinion accelerated tests are of no value in determining the durability of cements in practical use. If the committee means by this that in their present experimental stage the adoption of accelerated tests in cement specifications generally is of very doubtful wisdom, we think that most engineers who have studied the matter carefully will agree with it. But if the committee means to convey the impression that its experiments have shown accelerated tests to be entirely without promise of merit, its conclusions are open to grave doubt. Unfortunately all the data of the committee's investigations are not available for study, but judging from the abstract of the report furnished to us it seems to base its conclusions upon the fact that the cements selected for study stood the ordinary short time cold water test, and also, when made into large disk shaped medallions, endured uninjured an exposure of 1½ years in air despite the fact that the majority failed to withstand the boiling and hot water tests of Michaelis, Tetmajer and Maclay. With this evidence alone and with the record of previous tests in mind it may, we think, be fairly said that the conclusions of the committee do not stand proven. The fact that the cement pats tested by it withstood the cold water test has no place in the argument at all, for the reason that the advocates of accelerated tests deny the efficiency of the cold water test. On the other hand, the durability of the cement and sand medallions exposed 1½ years to the atmosphere is admissible evidence. It is, however, not conclusive evidence that the test pieces would not have failed ultimately. In the elaborate tests made by Prof. Tetmajer (Eng. News, Oct. 31, 1895), the majority of the cement pats exposed to air failed only after a year's time, and if we are not mistaken some of them lasted nearly three years but ultimately disintegrated. It may be possible that a longer exposure of the medallions in air would have confirmed the showing of the accelerated tests that the cements were unreliable. We are far from the opinion that the value of heat tests has been conclusively shown, but the evidence of most of the tests which have been made, and the attitude of such bodies of experts as the "German Conference Upon the Methods of Testing" and the "French Commission Upon Methods of Testing," speak strongly enough in their favor to warrant engineers in awaiting conclusive proof of their worthlessness before discrediting them altogether.

The municipal art number of "Municipal Affairs" deserves a word of special mention. This is a subject which has hitherto received scarcely any attention by the vast majority of our American cities. Perhaps more has been done in this way in connection with city parks than in any other manner, but even that has often been largely incidental to the main and proper object of providing places where people could get near to

nature rather than study art. Next to parks, and perhaps ranking first, municipalities have made an attempt at the artistic when providing themselves with city halls and school buildings, but here the results have more often than otherwise been disappointing, quite commonly through mistaking ostentatious display for artistic expression. The articles in the journal in question, which are mentioned more particularly under our New Publications, show the wide range of possibilities for municipal art, embracing the plan of the city; the material and character of its buildings, both public and private, including color effects; sculpture for parks, public places and buildings; mural paintings, and, finally, even such details as street signs, flags and banners. A radical change in municipal art might be accomplished without adding materially to city expenses. In fact, beauty would be cheaper than much of the ugliness so apparent in many of our cities. Art often depends more upon an appreciation of the appropriateness of things than upon the expenditure of additional sums of money. We should all do what we can as cities and as individuals to cultivate an appreciation of municipal art.

◆

The new needle dam on the Big Sandy River, near Louisa, Ky., which is fully described elsewhere in this issue, calls deserved attention to the very high character of some of the engineering construction which is now being done by Government engineers in developing slack water navigation on the rivers of the Ohio Valley and the South. This dam not only sustains a greater head of water than any dam of the same type previously built, but, what is of greater importance, its very successful operation with this unprecedented head gives promise that movable dams, if properly designed, can be built and operated with still greater lifts at a cost which is not exorbitant compared with that of fixed dams when we take into account the obvious advantages of the movable structure for securing slack water navigation. The object of damming a navigable stream is simply to conserve the water during the season of medium flow so that navigation can still go on uninterruptedly through the lock which is provided for that purpose. With a fixed dam the navigation must of course pass through the lock at all times, while with a movable dam it is possible upon the approach of sufficient water for free navigation to restore the stream to its natural condition by lowering the dam and thus throw the whole width of channel open to the passage of craft. This is a very material advantage in the case of many of our inland rivers where slack water navigation exists. A large bulk of the traffic in these streams consists of the shipment of coal in barges and lumber on rafts, which accumulate in vast quantities in periods of low water waiting for the first rise to take them to their destination. If the rise is of short duration the delay caused by passing everything through the lock may result in the failure of many of the accumulated craft to receive any benefit from the long-watched-for flood waters. Still another adadvantage of the movable dam is that in times of freshet it does not raise the flood level above its accustomed height in the original condition of the stream, and can therefore be applied safely to much higher lifts than can a fixed dam.

The one great drawback of movable dams, however, has been their expense, the explanation of which recent authorities have come to believe is to be found in the fact that they have nearly always been built with lifts which would allow of the needles being placed and removed by hand. Such a restriction of course makes the cost very great in proportion to the length of river made navigable, for the reason that the cost of the foundation and substructure, which constitute the bulk of the cost of a movable dam, is largely independent of the height of superstructure placed upon them. The most paying efforts in the direction of future improvements in movable dam construction, therefore, are those which lead to increasing the practicable lift with which they can be operated, and it is because of its decided advance over other dams in this regard that the Big Sandy River dam is particularly instructive.

The successful operation of this dam against a head of water of 12 ft., or nearly twice that of any previous dam, is made possible, as the article published elsewhere clearly shows, by the use of special appliances to handle the trestles and to place and remove the needles. In its broad features of design and operation the dam does not differ materially from the low lift needle dams constructed in many places both in the United States and Europe, but while previous dams have been kept pretty rigidly within that limit of height which would allow of the needles being maneuvered by hand, the Big Sandy River dam has been provided with machinery capable of handling needles of great weight and size, and the advantage thus gained has been utilized to increase the height of lift. There seems to be no insurmountable reason, moreover, why still more powerful and better adapted mechanism for operating the needles and trestles cannot be designed and employed, with a further gain in the height of lift with which a needle dam can be operated.

◆

The negotiations between the Manhattan Ry. Co. and the New York Rapid Transit Commission looking to extensions of the Manhattan Elevated Ry. system in New York city, which have been proceeding for some months, have finally come to a halt, and from present appearances are not likely to be resumed until Fall, if indeed they are not permanently closed. The rock on which the negotiators split was the rental of 5% of the gross receipts fixed by the Commission for the proposed line on West St. connecting with the Jersey City ferries and crossing the city at 13th St. to junctions with the present north and south lines of the system. Public opinion will probably be divided as to whether the Manhattan Co. really believed the rental asked for the franchise was more than it was worth; or whether it relied on the fact that it was the only bidder for what the city had to sell, to force down the price. The supercilious and insulting tone adopted, in the negotiations with the Rapid Transit Commission, by the young multi-millionaire and the sage dealer in puts and calls who control the destinies of the Manhattan Company, incline an unprejudiced observer to the latter view.

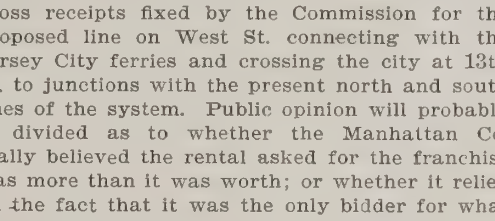
SOURCES, MODES OF SUPPLY AND FILTRATION OF PUBLIC WATER SUPPLIES IN THE UNITED STATES.

Through the courtesy of Mr. Benj. H. Flynn, of the graduating class of the University of Ohio, at Columbus, O., we are enabled to present a summary of the sources and modes of the public water supplies of the United States and the number and kind of the filtration plants in use. The figures formed a part of Mr. Flynn's graduating thesis. They were compiled from "The Manual of American Water-Works" for 1897. As originally tabulated the figures were so presented as to give the data separately for cities of six different sizes in four sections of the country. We have omitted the classification by populations, giving only the totals by groups of States. The boundaries of these groups are indicated on the accompanying map. In table I. we have added the three columns of sub-totals, and Table III. has been rearranged.



Sketch Map Showing Groups of States Used in Summarizing Water Supply Statistics.

Perhaps the three most striking things shown by Table I. are: (1) That 1,822 of the 3,356 sources of supply are wholly ground water; (2) that nearly all the filtration plants are connected with surface supplies, and (3) that while in some foreign countries nearly all surface supplies are filtered, this being practically required by law in Germany, in the United States only 14 per cent. of the surface supplies have even the name of being filtered. That some of the so-called filtration plants are of no real value is a fact spoken of further on. It is true that many of our surface supplies are from such sparsely settled, rocky and wooded districts as to insure great natural purity, but this by no means accounts for the difference in practice between our own and foreign countries. There are indications that we are on the eve of a great change in this respect. Many filtration plants are under construction or proposed, and at the water-works conventions it is becoming more and more common for speakers to state as their opinion that in the future all surface supplies must be filtered. It is not organic matter or sewage pollution alone that makes filtration of surface waters necessary or desirable. Turbidity and color are objectionable to say the least. In practically all of the Southeastern section, in much of the North Central, and in all but the mountainous portion of the great Western section, and even in some parts of that, turbidity is present in all surface waters, and at times is almost intolerable. Settling reservoirs are employed in many cities, but on the whole they are comparatively few in number and diminutive in capacity, besides which they must in many cases be supplemented by filtration if an agreeable water is to be supplied.

Although so few of our ground water supplies are being filtered, by no means all of the remainder are above suspicion of sewage pollution, and later years will doubtless show a great increase in filtration plants for the removal of iron, of which some half dozen or less have been built.

The large number of ground water supplies in use, coupled with the many plants where water is pumped to reservoirs, shown by Table III., suggests another broad field for engineers and contractors; the covering of storage reservoirs. Of course not all the reservoirs indicated in Table III. are used to store ground water, but some storage, even if small in amount, is frequently provided wherever ground water is used. When exposed to the sun such water is likely to give rise to various organic growths which, while entirely harmless in themselves, cause very unpleasant tastes and odors. Such troubles can often be avoided by covering the reservoirs. The practice is common abroad but has been followed but little here, especially for large reservoirs. Roofs or coverings in Europe have commonly been of masonry, and it has often been thought, essential to have the covering surmounted with earth, thus increasing the load to be borne. Most reservoir coverings in this country have been of wood. So far as we know they have served their purpose very well, but whether as well in all cases as masonry, and whether they will prove as cheap as masonry in the long run we will not attempt to say.

Before leaving Table I. it should be said that of the 502 sources of supply credited to springs probably some are quite as truly surface waters, spring water having so very attractive a sound that it is sometimes applied to water from small streams which, while undoubtedly spring-fed, yet derive a goodly portion of their yield from surface flow. It is also true that many surface supplies are greatly augmented by springs.

The number of filtration plants of the various types is shown by Table II. The total here is 60 greater than in Table I., owing to that number of filter galleries added to this table. It must not be understood that there are 291 (or 231 on omitting the galleries) efficient filtration plants in the United States. Practically all of the 66 plants under the heading "Miscellaneous" and some of those under "Sand Filters" really ought not to be classed as filter plants, being at best only screens, and in some cases poor ones at that. Doubtless there are 126 mechanical filter plants in the country. The majority of these were put in to improve the appearance of the water rather than to remove organic pollution, but some of them are doing good work in both lines, and probably all, or nearly all, are greatly improving the water in one way or another. As to the actual number of effective sand filters in use it may be said that the June issue of the Journal of the New

*Filtered supplies do not include those where the water is collected by filter cribs and galleries, of which there are 60, as shown by Table II.

England Water-Works Association contains a list of 14 plants, compiled by Mr. Allen Hazen, Assoc. M. Am. Soc. C. E., and including all which he deemed worthy of the name. Some of these, we believe, were not in use when the "Manual" was published. It is quite probable that some of the 25 plants which are in Mr. Flynn's list but not in Mr. Hazen's are doing fairly good work, at least as good as some of the mechanical filter plants. Filter galleries, in many instances, are designed more to develop a supply than to filter one, in which case they are comparable with driven wells. These comments on the filtration statistics are not to be taken as reflections on either Mr. Flynn's work or on the "Manual," as each aimed to give such information as was available for what it was worth.

Little need be said regarding Table III. except to call attention to the number of water-works relying wholly upon direct pumping, 418, and the number of stand-pipes (which term includes tanks) in use, 1,465 in all, not allowing for the fact that there are two and sometimes more of these structures connected with some water-works. It would be interesting to see a classification of stand-pipes by material and date of erection, and to note the exact majority of steel over iron in the last few years. As against 1,465 works in which water is pumped to stand-pipes there are but 671 instances of pumping to reservoirs. Of course there are hundreds of additional reservoirs used on gravity supplies, nearly one-fourth of all the water-works in the country depending on gravity works alone.

*Stand-pipes includes all tanks and metal structures to which water is pumped.

The distribution of the various sources and modes of supply by sections is interesting, as may be seen by referring to the tables.

Two interesting facts brought out by Mr. Flynn's population groupings may be noticed: (1) That only two places with 50,000 population or over, and only eight with over 25,000 population are getting their supplies wholly by gravity, and (2) that five places with more than 50,000 inhabitants and 19 with more than 25,000 are depending wholly upon direct pumping. The towns having a population of 5,000 or less contribute 656 of the 736 gravity supplies, 291 of the 418 direct pumping works and 847 of the 960 works where water is pumped to stand-pipes, none of the combined systems being included in any of the figures. It should be borne in mind that these towns of 5,000 or less make up 2,569 of the 3,281 public water supplies included in Table III.

In conclusion it may be said that the figures we have reviewed indicate the vastness of the water-works interests of the country and give some hints of the opportunities for further improving our public water supplies, especially in the matter of quality.

LETTERS TO THE EDITOR.

The Graham Automatic Draw-Bar Height Adjuster. —Correction.

Sir: In the brief description of our automatic draw-bar height adjuster in your issue of June 16 we wish you would correct the statement that it is not in general use. We have been equipping our trucks since June, 1894, with this device, and it is in service in both the United States and France. Car builders to-day have to meet two very great difficulties, keeping the draw-bars at a proper height from the rail, and finding ample space between car and truck so they can increase the depth of both car and truck bolsters to provide for the increased carrying capacity. Our adjuster will permit increasing the general height of the car from the rail fully 6 ins. and comply fully with the law, which states that the draw-bar on an empty car must not be higher than 34½ ins. With our adjuster, when the car is loaded and the springs are deflected 3 ins. the draw-bar would be 37½ ins. from the rail, a difference of 6 ins., which is a clear gain for the car builder in which to increase his bolsters. The adjuster will never drop the draw-bar below the point set when car is empty, and as the load always carries the draw-bar upward, there is no fear of having it below the minimum 31½ ins. The law has not said anything about how much above 31½ ins. the draw-bar of a loaded car must be; it simply states that it must not be below 31½ ins., therefore anything above that point is within the requirements of the law. Sincerely, The Graham Equipment Co.

Boston, Mass., June 21, 1898.

A Theory for Placing Stiffeners in Plate Girders.

Sir: In your issue of June 9 there appears a criticism by "E. M." of Mr. Beach's letter (Eng. News, May 19) on stiffening plate girders which deserves some comment. In attacking the views of another the burden of proof rests with the critic, and this "E. M." seems to have entirely forgotten while making his assertions. Thus he asserts that the analogy between a stiffened plate girder and a Pratt truss exists neither in theory nor in fact, as Professors Johnson and Burr have pointed out that it did not, but he fails entirely to offer proof himself or to state where these authorities have given it.

A careful study of the discussion on the internal stresses in the stiffened plate girder brought out by Mr. Joseph M. Wilson's paper on "Specification for Iron Bridges" (Trans. Am. Soc. C. E., 1885) is disappointing indeed, since the eminent mathematicians who took part in it appear to have expended their energy rather in trying to decide what the master mind of Rankine might or might not have thought on the subject than to solve the problem themselves.

In discussing the condition of internal stress in any given structure it is well to bear in mind that it is not a Professor but Dame Nature herself that actually determines the stresses, and that the Professor, notwithstanding his learning, is frequently a forgetful fellow, leaving out of consideration a few of the practical conditions of the problem and thus arriving at conclusions inapplicable to the case in hand. Dame Nature, on the contrary, not only understands fully how to allow for all practical conditions, but never forgets them, and the result is that her determinations are ever rational and accurate beyond question.

Moreover, she is ever a willing teacher, ready to answer all questions to him who but possesses the ingenuity to ask them in the right way, and she frequently discloses her methods to the practical observer.

Evidently the first step towards arriving at a rational method of proportioning stiffness is a rational analysis of the internal web stresses of the stiffened girder. The treatment of this subject in most of our text books is of little value, since their authors have apparently forgotten the practical condition that when the stiffeners are riveted to the web they form a part of it, and cannot therefore be disregarded in any logical analysis of the internal web stresses.

About nine years ago, while looking over a girder viaduct, the writer noticed a web plate slightly buckled in the end panel of a deep girder, and just then a heavy freight train coming upon the girder this buckle appeared to pull out flat for a width of about a foot along the tensile diagonal of the panel, indicating action similar to a Pratt truss as the buckle resumed its previous form after the train had passed. The correctness of this observation appears to have been verified by a laboratory experiment, noted in your issue of Oct. 28, 1897. The buckled web of the girder used in the experiment referred to was regular in form, so that its distortion under load indicated the direction of the maximum web stress beyond question.

In stating that the proportioning of stiffness and also the spacing of them is merely a matter of guess (empiricism), and that Mr. Beach's guess is wrong because slightly different from his, "E. M.," has not given a very logical reason for the criticism. Respectfully yours,

June 15, 1898. "Practical Bridge Builder."

A Visit to the Virginia Military Institute.

Sir: It is just ten years since I left my native Pennsylvania and became a citizen of the "Mother of Presidents." Although my professional duties made it possible for me to roam over nearly the entire state, and thus become intimately acquainted with the geography, yet it had never been my good fortune to visit the "Athens" of the South, the historic town of Lexington. And stranger yet to admit, the cause of my first visit to this place so revered by Virginians, was due to my being officially connected with a Sunday-school picnic excursion. The town of Lexington is situated in the heart of the famous Shenandoah Valley; and "Yankee" though I am, I must admit that, if there is any "Switzerland of America," Lexington is its center. The sublimity of its surrounding scenery is indescribable, and the exhilaration of its atmosphere! Why, even an engineer corps of the old school type could become total abstinence men and still be gay and happy there.

Lexington is the home of the Virginia Military Institute, a famous old school endowed by the state of Virginia, and is also the seat of the still older Washington and Lee University. The grounds of these schools join each other. The location is an ideal one, on the crest of a high ridge or plateau, overlooking North River. Your readers will also recall the fact that beneath the sod of Lexington rest Robert E. Lee and Stonewall Jackson, whose very names inspire the hearts of all true men.

While on my visit, it was my very good fortune to meet

Col. R. A. Marr, professor in charge of the Department of Engineering and Drawing, of the Institute.. And, by the way, I think it was a kinsman of the Colonel who was the first soldier to lay down his life for his cause in the Civil War. Col. Marr, who spent 13 years of his life on the U. S. Coast Survey, is a Virginian by birth, and it is unnecessary to state that he left nothing undone which could conduce to my comfort and pleasure. Under his guidance I visited the various departments of the institution, and I was indeed astounded with what I witnessed when I came to visit his own department. An engineer well knows that practice necessarily precedes instruction, and that institutions of learning must, as a rule, be content to follow rather than lead, and in patience await the advent of a treatise or text book before instructing their students respecting the new methods and appliances which are continually being brought forward. I was astonished, therefore, when Prof. Marr showed me plans, profiles, specifications, models, etc., of a large number of engineering works recently completed or now in progress. How gratifying all this was to me can well be understood when I recall the graduates of some other first-class institutions who have applied to me for employment; and, after examining them as to their knowledge of present-day methods of work, I found that, so far at least as railway work was concerned, their methods had long been superseded by more advanced and economical ones. Col. Marr may well be congratulated on the fact that his graduates are not filled with antediluvian methods, but can enter into the whirl of present-day practice with that sense of security which characterizes an "old timer." It is needless to say that the physical culture of the young men is as carefully looked after as is their mental training.

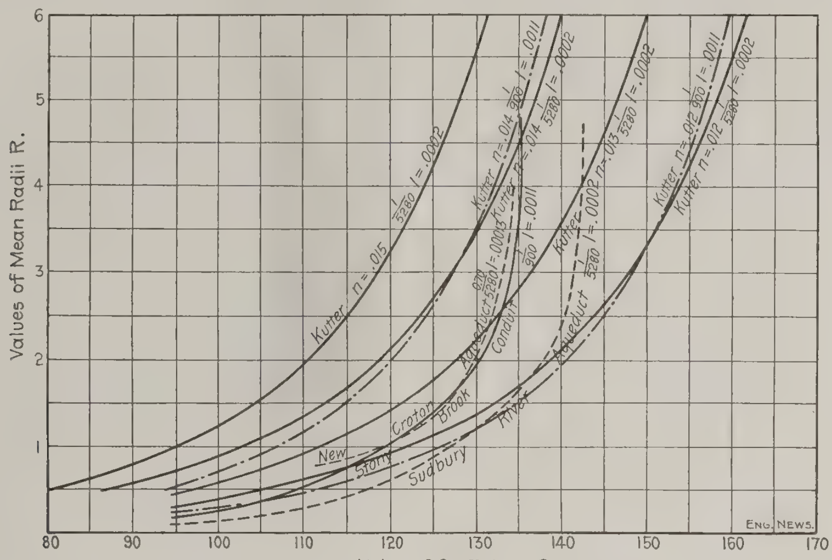

FIG. 1.—APPROXIMATE CURVE OF COEFFICIENT C ADOPTED FOR THE STONY BROOK CONDUIT, COMPARED WITH OTHER CURVES FOR C.

James Francis Desmond, Assistant Engineer.

It is probably unnecessary to say, in conclusion, that Engineering News finds a conspicuous place in the Professor's teachings.

Theo. Low,
Supt. N. & W. Ry.
Lynchburg, Va., June 27, 1898.

The Design of Extensions to the Stony Brook Conduit, Boston, Mass.

Sir: Believing that the results of a careful investigation relative to the design and determination of discharge for various depths of a large brick channel to provide for the storm water flow from a drainage area of about 12½ square miles, which I recently had occasion to make, may be of interest to engineers engaged in that class of hydraulic work, I present them herewith.

These conclusions are presented simply as the result of a graphical analysis of 260 gagings on various channels lying within certain limits in regard to the coefficient of roughness.*

It has been the common practice in this Department to use Ganguillet and Kutter's curves for C, assuming .015 for sewers and storm water channels of any diameter and value of R.

In the year 1886 a commission composed of Messrs. Jas. B. Francis, Eliot C. Clarke and Clemens Herschel was appointed to report measures for the prevention of floods in this territory. They reported that the maximum flood discharge should be taken at 2,000 cu. ft. per sec. after the district had become well built up, and that a well built channel nearly 17 ft. in diameter with an hydraulic gradient of 1 in 900 would be required to provide for this quantity. They used the expression

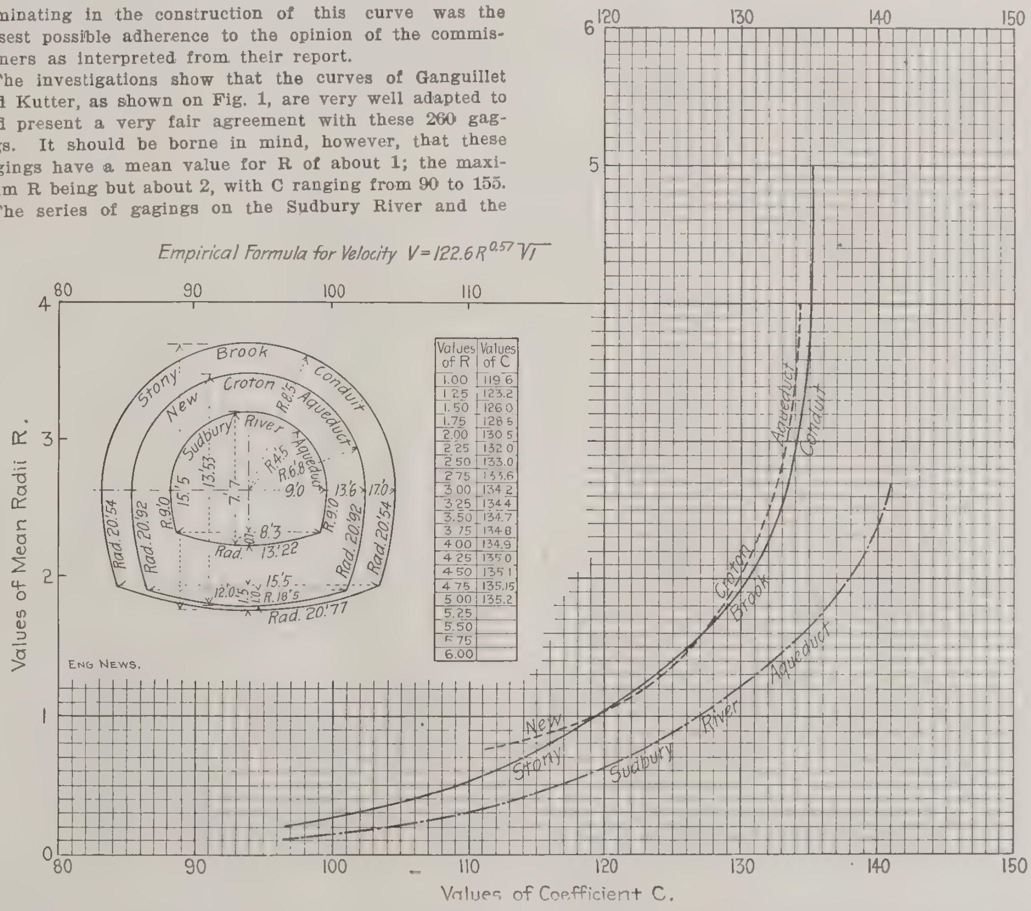
$$v = c\sqrt{RI},$$

assuming a value for $C = 135.0$ when $R = 4.25$. On their recommendations 4,500 ft. of channel were built in that year. At various times since the channel has been continued along the lines laid down by the commission. Up to the time of writing nearly 12,000 ft. have been built.

It becomes necessary now, for various reasons arising since 1886, to deviate from the commissioners' lines; to change the location; lower the hydraulic gradient, thereby increasing the size and with it the hydraulic mean radius, the latter to about 5 ft. These changes necessitated the adoption of a curve for C in relation to R for greater values of R for the main channel, and lesser values of R for branch channels. The influence predominating in the construction of this curve was the closest possible adherence to the opinion of the commissioners as interpreted from their report.

The investigations show that the curves of Ganguillet and Kutter, as shown on Fig. 1, are very well adapted to and present a very fair agreement with these 260 gagings. It should be borne in mind, however, that these gagings have a mean value for R of about 1; the maximum R being but about 2, with C ranging from 90 to 155.

The series of gagings on the Sudbury River and the new Croton Aqueducts were plotted as shown on Figs. 1 and 2, and these gagings were finally used as the basis for the curve under consideration as best representing this form of channel and this class of work; although, as will be noticed, there is no harmony between these curves and Ganguillet and Kutter's for value of R greater than 1.5.



Values of R	Values of C
1.00	119.6
1.25	123.2
1.50	126.0
1.75	128.5
2.00	130.5
2.25	132.0
2.50	133.0
2.75	133.6
3.00	134.2
3.25	134.4
3.50	134.7
3.75	134.8
4.00	134.9
4.25	135.0
4.50	135.1
4.75	135.15
5.00	135.2
5.25	
5.50	
5.75	
6.00	

FIG. 2.—APPROXIMATE CURVE OF COEFFICIENT C ADOPTED FOR THE STONY BROOK CONDUIT, BASED ON THE GAGINGS OF THE SUDBURY RIVER AND NEW CROTON AQUEDUCTS.

The empirical formula

$$v = 122.6\ R^{0.57}\sqrt{I}$$

deduced from this curve, I believe to be at least worthy of consideration in calculating the discharge of storm water channels of this form and class of work—that is, for good, clean brick, well made joints and easy curves for values of R from 1 to 5, with I varying from 0.001 to 0.0002. Perhaps the range given to I may be considered by engineers as rather a wide one, but I have reason to believe, from a close study of the matter, that the variations in C due to this are slight.

In the absence of more material on which to build I leave to the judgment of the engineer the real value of this curve.

Very respectfully,
James Francis Desmond,
Assistant Engineer, Sewer Department.
28 Court Square, Boston, Mass., June 1, 1898.

---

*These gagings may be found in Hering and Trautwine's translation of Ganguillet and Kutter's "A General Formula for the Uniform Flow of Water."

The New York Fireproofing Tests.

Sir: An inquiry received this morning from a customer of ours leads me to address you for some information, thinking that as a public newspaper you might be able to secure answer to certain inquiries that we cannot.

This customer of ours writes to know where he can secure printed reports of the fireproofing tests made by the Building Department on our form of construction, together with others made about the same time.

You doubtless will remember that during the fall of 1896 and the spring of 1897, fireproofing tests were going on very frequently. There occurred, within twelve months, not less than 20 in all, at an average cost to each of the individuals or concerns, whose materials were tested,, of not less than $1,000, to say nothing about a still vaster sum of official red tape that enveloped the whole transaction.

It was a public boast that these tests were to be the most famous in the history of building material. But alas! the $20,000 and miles of red tape, have apparently all gone for naught. Each of the concerns, whose material was tested, received an official document entitled "Result of the Test." They were written, doubtless, weeks after the tests themselves. This I say, for the reason that the reports were very cold and deep. The reports were merely a mass of figures, indicating temperatures, strains, etc., with no conclusions drawn or other statements made which would in any wise guide the inquiring, interested public.

The inquiry I desire to make of you is: "What benefit was the expenditure of all this money to the public, or for that matter to the people who expended it?" Why were not the reports of these official tests published? We are told that the building department to-day refuses to acknowledge the existence of any such tests. The engineers of the department will not even refer to the records on file, to establish the slightest fact connected with any part of the test.

The situation savors very strongly of "a Senegambian in the lumber heap." Will the vigorous inquiry department of the Engineering News please find him, and much oblige one of the contributors to the $20,000 expense fund?

Very truly yours,

A Cash Sufferer.

New York, June 21, 1898.

(We presume our correspondent can answer the questions which he propounds quite as well as we. As some of our readers may not be so well informed, however, we will endeavor to answer his questions. In the first place, the tests of fireproof floors to which our correspondent refers were in many respects well planned, and did give a great amount of valuable information to the profession as to the strength and fire-resisting powers of the styles of fireproof floor construction. The reports of these tests, which were published in Engineering News, give fairly complete records of their results. It is certainly unfortunate that an impartial and concise report of all the tests was not published by the city authorities at their close, and we can hardly blame those who contributed to this "$20,000 expense fund" for feeling very sore at its absence. The reason why no such report was made, to the best of our knowledge, is first, that such reports as were presented were so long and detailed that their publication would have been of little benefit to any one, and second, that lack of harmony between the Superintendent of the Building Department then in office and the city financial authorities prevented any appropriation of funds for this purpose.

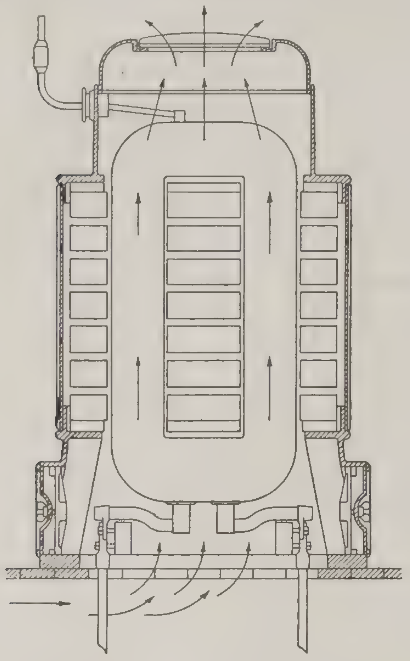

Fig. 1.—Section of Air Blast Transformer Showing Direction of Air Current.

General Electric Co., Schenectady, N. Y., Builders.

As to the reason why the present administration ignores the results of the tests made during the last administration, we thought best to let the administration speak for itself, and with that in view we submitted a proof of this letter to Superintendent Brady, of the New York Building Department with an invitation to present a reply for publication in connection with the above letter, in accordance with our usual rule when communications sent for publication contain matter criticising the acts of any person.

That official, however, has made no reply whatever, and after waiting ten days we are compelled to conclude that he has no reply to make. Comment on the autocratic methods in the Building Department which our correspondent's inquiry discloses is needless.

We deem it well to call especial attention to the things set forth in the above letter, because other city authorities are apt to look to New York, the largest city in the country, for guidance in the matters of building laws and building inspection. If they do so now they should do so with the full understanding that not a few things in the New York law and its administration are the result of influence and political pulls, without regard to the real value of materials and methods from an engineering point of view.—Ed.)

METHODS OF COOLING TRANSFORMERS OF LARGE SIZE.

The transformer, as its name implies, is a device for changing electric energy furnished under one set of conditions to the same kind of energy for use under a different set of conditions. This transformation is accomplished by making use of induction and the magnetic properties of iron, but with a loss which is greater or less according to the character of the material used, its amount and its distribution. The loss always takes the form of heat, which must be dissipated as fast as generated or it will gradually accumulate in the transformer and raise its temperature to a point where serious injury will be done to the insulation. The removal of heat from a large transformer is really the element on which its capacity chiefly depends, and provision for it is therefore among the most important elements in its design. Small transformers have so large a surface in proportion to their bulk that they are sufficiently cooled by radiation and the natural circulation of air about them. As the size increases, however, the ratio of the volume to surface exposed also increases, and artificial means of cooling become necessary for both economy and safety. If these are not employed the designer must depart from the most compact and most economical proportions and sacrifice material and strength to obtain sufficient external surface to radiate the heat. It is usually necessary for mechanical protection to enclose the transformer, and this materially interferes with the cooling by natural radiation.

A practice in extensive use with transformers of moderate size is filling the case with oil, which acts as both an insulating and a cooling medium and considerably increases the capacity. Various designs have been adopted in which provision is made for the circulation of the oil through the interior of the transformer. If ducts passing entirely through the body of the winding are provided, however, they must be narrow or the size and cost of the transformer will be excessive and the efficiency low, not to mention the greater space required. On the other hand, with narrow ducts oil is not a reliable cooling medium. Its circulation under the best conditions is sluggish, while the ducts tend to close gradually from the swelling of the insulating wrapping on the coils and the collection in the ducts of a deposit derived from the slow solution of the various liquid insulations employed when winding the coils.

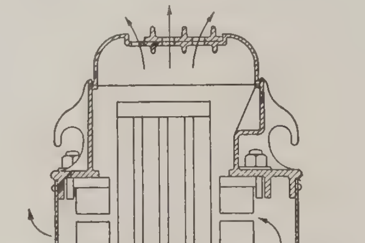

Fig. 2.—Section of Air Blast Transformer Showing Position of Coils, Core, and Casing and Direction of Air Currents.

To overcome these drawbacks a new design was introduced in which the height of the laminated core is small compared with the external dimensions of the punchings. A large proportion of the copper is external to the core, and the exposed ends are so spread apart as to give wide openings between the coils for the access of the oil. This design insures a low temperature in the exposed part and even a moderate average temperature (measured by increase in resistance), but the central portion often becomes dangerously hot without giving any direct evidence of the fact; and it is of course no less serious to have a high temperature in any part of the transformer than to have the entire winding at an unsafe temperature.

In large transformers the use of oil is undesirable for reasons other than its poor efficiency as a cooling medium. Small transformers are usually installed out of doors and contain so small a quantity of oil that danger from fire is almost impossible. Large transformers, on the other hand, form ordinarily part of extensive plants, many units being banked together within a single building, and the chances of fire would be greatly increased by the use of oil. Moreover, it is almost impossible to make large transformer cases oil tight. For these reasons satisfactory results are not obtainable with large transformers if dependence is placed entirely on external surface heat regulation or on oil as a cooling medium.

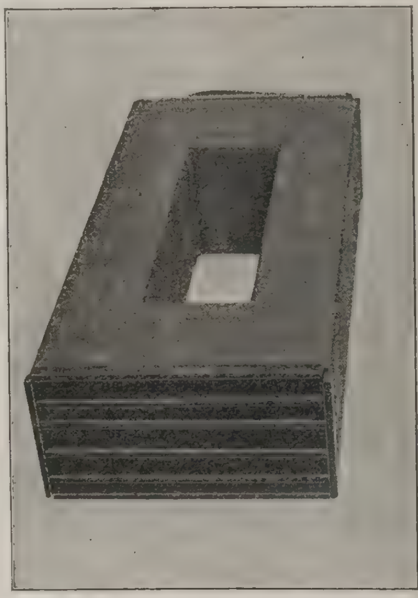

Fig. 3.—Coils Assembled with Diaphragms in Place and Insulation On.

The General Electric Co. has adopted the air cooling system for its large transformers. In this type of transformer currents of air are made to pass through small ducts and channels in the interior of the transformers and take up the heat from the large amount of surface thus exposed. Two methods are employed as standard practice by the General Electric Co. in the construction of its large transformers. In the "Air Blast" type, Figs. 1, 2 and 5, the current of cool air is forced upward through the core and windings. In the "Natural Draft" type the coils and core are so proportioned and placed that large surfaces are exposed and the temperature kept within safe limits by the natural circulation of the air. In the "Air Blast" type the cooling current of air is obtained from a motor-driven blower and is forced from below through separate paths at right angles to each other vertically through the windings and horizontally through the core, Figs. 1 and 2. The admission of air is controlled by shutters at the top and at the sides of the transformer. The power used by the blower seldom exceeds ¼ of 1% of the total capacity of the transformer, and in most cases is much less, frequently not more than 1-10%. It is considerably less than that which would be required to pump oil through an oil-cooled transformer of the same capacity.

The air blast type is designed for continuous operation, large output and high potential. In it the windings are subdivided into numerous independent coils, each separately and heavily insulated. With such subdivision the voltage generated in a single section is low, even in transformers wound for a voltage of 15,000 to 20,000 volts, and the numerous air ducts between all the coils which this subdivision allows in addition to the spaces in the iron lamenation of the core, Fig. 4, limits the rise in temperature to a few degrees. The coils are wound with flat copper conductors cemented together by an insulating compound before the exterior insulation is applied. The use of rigid coils is important in large transformers since the magnetic force tending to move the conductor is great, and vibration, abrading the insulation, might be set up. The primary and secondary coils are assembled in small intermixed groups with air spaces between the coils, and between every adjacent primary and secondary section are solid insulating diaphragms which completely encase the primary winding except at either end of the core, necessarily left open to allow the air to circulate freely. At the end, however, the diaphragms project far beyond the coils, so that a surface insulation of great extent is provided between the primary and secondary. An additional insulation casing is placed around the entire structure of assembled primary, Fig. 3, and secondary coils and separates the whole winding from the iron punchings assembled within and around them. The method of insulation employed assures a factor of safety of at least 3, and the insulation test between the high potential windings and the core is made at a voltage equal to twice the rated potential.

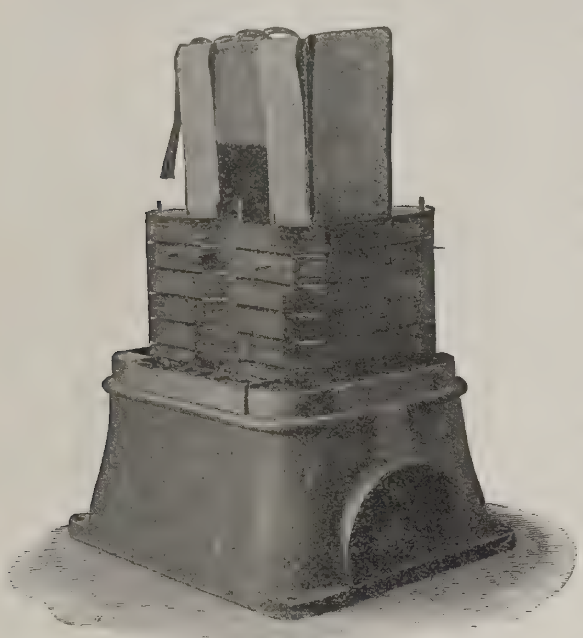

Fig. 4.—Building Up the Core, Showing Assembled Coils in Place and Core Partially Built Up.

Calculating the temperature of the interior of the air blast transformer by the rise in resistance of its windings, the rise in temperature is guaranteed not to exceed 40° C. above that of the surrounding air.

Air blast transformers are used on 15,000 volts potential or less, and are constructed for higher potential when necessary. Over 100,000 HP. in these air blast transformers have been installed, and no record yet exists of a burn-out due to heating or overload.

ANNUAL MEETING OF THE ASSOCIATION OF GERMAN PORTLAND CEMENT MANUFACTURERS.

Abstracted by S. B. Newberry, Assoc. M. Am. Soc. C. E.,[*] from the Official Report.

The annual meeting of the Association of German Portland Cement Manufacturers took place in the audience room of the Architects Institute, Berlin, Feb. 23 and 24, 1898. The membership of the association includes representatives of 83 factories, having a total production in 1897 of 17,150,000 barrels of Portland cement. This production is divided amoung various countries, as follows:

Germany 66	factories,	product	14,950,000	barrels.
Austria 10	"	"	1,150,000	"
Other countries.... 7	"	"	1,050,000	"
Total 83	"	"	17,150,000	"

The United States is represented in the association by one factory only, the Alamo Cement Co., of San Antonio, Texas.

Dr. Prussing reported on the unfair competition of the "Natural Portland Cements" of Belgium against the true artificial Portland cement of Germany. These Belgian cements are chiefly made by the direct burning of a limestone of approximately the composition of a correct cement mixture. The variations in the proportions of lime and clay present in the rock, however, cause great fluctuations in the quality of the product, and much of the Belgian cement is greatly inferior to true Portland. Most Belgian manufacturers sell their product under foreign labels as "Portland cement of highest quality," and in many cases well-known German labels are purposely counterfeited.

At a meeting of English and German cement manufacturers, held in Cologne in July, 1897, it was resolved to take the following steps to meet this fraudulent competition:

1. Samples of Belgian natural cement are to be purchased in open market and tested at the Royal Testing Station at Charlottenburg, and by competent experts in England.
2. An attempt is to be made to secure from the Belgian government an official definition of Portland cement.
3. A pamphlet is to be published, showing the untrustworthiness of the so-called "Natural Portland cements," and stating the names of the Belgian factories which produce a genuine and reliable article. This pamphlet is to appear in German, English, French and other languages, and is to be circulated as widely as possible in all countries.

Report of the Committee on the Action of Sea-Water on Hydraulic Cements.

R. Dykerhoff stated that the committee had decided to extend their observations over a period of 10 years. A part of the test-pieces of the series of 1896, exposed to the action of sea-water at the Island of Sylt, were destroyed or damaged by heavy storms. Only the rich cement mortars, especially those of Portland cement and sand, 1 to 1, had perfectly resisted the mechanical and chemical action of the sea. Poorer mixtures, and especially the trass-lime mortars, were more or less attacked.

At the meeting of the committee, held in February, 1897, it was resolved to limit the experiments, for the present, to the determination of the effect of the addition of trass on the resistance of Portland cement mortar to the action of sea-water. Trass is a volcanic scoria found near the Rhue, and similar to the Pozzuolana of Italy in its power of conferring hydraulic properties upon slaked lime. According to Dr. Michaelis, trass has the power or neutralizing the possible injurious effect of the high proportions of lime contained in Portland cement, and thus increasing its power of resistance to the chemical action of sea-water. This view is opposed by many of the leading authorities on cement, who have shown that dense Portland cement concretes have given excellent results over long periods of years when exposed to the action of the sea.

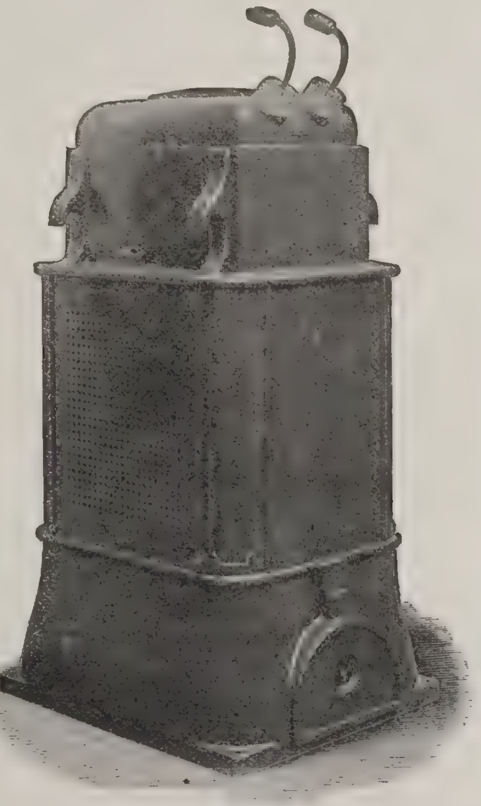

Fig. 5.—Transformer Completed with Cap and Casing in Place.

The committee decided to make a long series of tests of the effect of trass, using

1. A cement high in lime and low in alumina.
2. A cement high in lime and high in alumina.
3. A cement low in lime and high in alumina.

These are to be tested with various proportions of sand, with and without the addition of trass. The test pieces are to be placed in sea-water in such a manner as to be protected from the direct force of the waves, but exposed to the ebb and flow of the tide. Tests are to be made at 7, 28 and 90 days, 1 year, and longer periods.

Referring to the possibility of chemical action between the silica of trass, or other forms of silica, and the lime set free in hardening of cement, Dykerhoff referred to an interesting paper lately published by Lunge[*] on the action of various forms of silica on caustic alkalies and alkaline carbonates. Lunge found that quartz, a form of silica generally considered entirely insoluble in alkalies, may be rendered considerably soluble in caustic alkalies or even alkaline carbonates by extremely fine pulverization (elutriation). It might therefore appear probable that very fine quartz sand may enter into combination with the lime set free in the hardening of cement. To determine whether this is the case, Dykerhoff made a careful series of tests with mixtures of cement and natural sand, 1 to 2 and 1 to 4, in which one-half the cement was replaced by

1. Sand passing a sieve of 28 meshes to the inch.
2. Ground sand passing a 75-mesh and retained on a 177-mesh sieve.
3. Ground and passing a 177-mesh sieve.

Complete tables showing the results obtained are given in the report, but would occupy more space than can be allowed in this abstract. It was found that the replacement of one-half the cement by fine sand lowered the strengths materially, but that the finer the sand was ground the less the strength was reduced. From this it might appear that some chemical action between the fine sand and the cement had taken place. The comparative weight of the briquettes showed, however, that the decrease in strength was nearly proportional to the density, and that the higher results obtained with the finely ground sand are probably due to more perfect filling of the voids.

In order to determine whether a slight chemical action might not have taken place, the effect of finely ground sand and finely ground marble were compared. Both sand and marble were ground to pass a 177-mesh sieve. The results were as follows:

Tensile Strength in Pounds Per Square Inch.

	400 cement, 1,600 normal sand.	400 cement, 200 grnd. sand, 1,-600 normal sand.	400 cement, 200 grnd. marble, 1,600 normal sand.
7 days.................	221	256	255
28 days.................	249	307	307
90 days.................	309	366	372
Weight of 5 briquettes..	786 grams	825 grams	820 grams

From the above table it will be seen that the two finely pulverized materials have increased the strength equally. Since the carbonate of lime of the mortar is chemically entirely inactive, it is evident that the finely divided sand has exerted no chemical action. Whether a slight chemical effect may take place at long periods is of no consequence from a practical point of view. The use of finely ground sand to increase the strength of poor mixtures of cement and coarse sand will hardly be applied in practice, since equal, or even higher strengths can be obtained by the use of natural sands of graded fineness. This is shown by the following comparative tests at 90 days:

	Tensile strength.	Weight of 5 briquettes.
400 cement, 1,600 normal sand......	309	786 grams.
400 cement, 200 ground sand, 1,600 normal sand	366	825 "
400 cement, 1,800 Rhine sand........	362	805 "
400 cement, 1,600 Rhine sand.......	426	827 "

This table shows how the density and strength of mortars are influenced by the character of the sand employed. In marine constructions the density of the concrete, as well as its strength, is of great importance. It is therefore especially necessary, in this class of work, to select sands containing the smallest possible proportion of voids.

Calcium Hydroxide, Ca (O H_2), in Hardened Portland Cement.—Professor Schuliatschenko presented an account of the investigations of Ljamin, a Russian engineer, on this subject. Le Chatelier, in 1885, advanced the view that the hardening of Portland cement consists in the conversion of the tri-calcium silicate, 3 Ca O, SiO_2 under the influence of water, into a crystalline mass of hydrated mono-silicate and calcium hydroxide. This view was founded on a microscopic study of the process of hardening. Ljamin finds that it is possible to separate the hydroxide from the other constituents of hardened cements by use of a mixture of methylene iodide and benzol, of a specific gravity of 2.3. In this liquid the hydroxide (sp. grav. 2.1) rises to the surface, and may be quantitatively determined. He finds that the proportion of hydroxide in hardened cement increases rapidly during the earlier stages of the hardening, and reaches 31 to 33% at 90 days. After this time the increase is slight.

This result was confirmed by another method, based upon the different temperatures at which the hydrated silicates and the hydroxides give up their combined water. According to Ljamin, the hydrated silicates are decomposed at 160° C., while a temperature of 480° C. is required to decompose the hydroxide. The results obtained by the two methods agree very closely. These observations, and also the remarkable parallelism which is shown in the progressive gain in strength of cements and the percentage of calcium hydroxide formed, served as an important confirmation of the Le Chatelier hypothesis.

---

[*] Manager Sandusky Portland Cement Co., Sandusky, O.

[*] Thonindustrie Zeitung, 1898, p. 800.

Roman (natural hydraulic) cement, on the other hand, showed after 60 days hardening only 2% of hydroxide. It is evident, therefore, that the reactions which take place in the hardening of Roman and of Portland cement are radically different.

For the purpose of studying the effect of sea-water on Portland cement, Ljamin analyzed samples from well-preserved blocks of concrete which for 30 years had been exposed to the water of the Black Sea at Potihafen. These blocks showed a very hard crust, about one-eighth of an inch thick, on their surface. This crust contained 20% of carbon dioxide. One-fourth inch from the surface the proportion of carbon dioxide was only 5%, and at a depth of 1 in. only traces were found. Free calcium hydroxide was not found in the outer crust, but in the interior of the blocks this substance was present to the amount of 33%. It is evident, therefore, that the presence of large amounts of free hydroxide in hardened cement is no cause of injury by sea-water.

Report of the Committee on Tests for Constant Volume of Portland Cement.—A series of experiments on tests of constant volume was begun early in 1896. Ten Portland cements which were thought to be imperfect in the matter of constant volume were assigned to the various members of the committee to be independently tested. In addition, a number of medallions, 12 ins. in diameter and 1¼ ins. thick, and rosettes 10 ins. in diameter and 2 ins. thick, were prepared with the same cements. These were made with a surface of one of cement to one of sand and filled in with mixtures of cement one, sand two, and cement one, sand four. The medallions and rosettes so prepared were kept damp for three days in a closed room and then exposed to the weather.

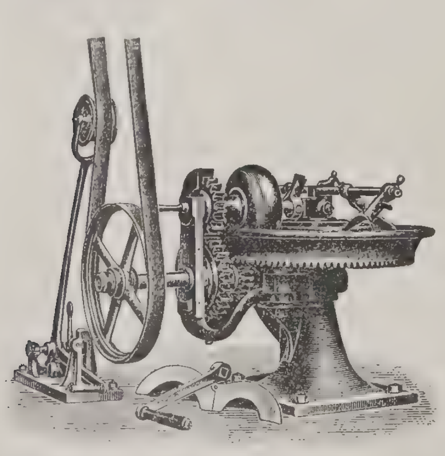
The ordinary cold pat tests of all the ten cements were fully satisfactory. Accelerated tests at higher temperatures gave varying results. Most of the samples stood the oven test at 100° C., but the majority failed in the Michaelis and Tetmajer boiling tests and the Maclay hot water test. No cement passed all the accelerated tests satisfactorily.

Observations of the medallions and rosettes after exposure of 1½ years to the weather showed that all were hard, well preserved and faultless. It is generally agreed that the durability of artificial stone prepared from a given Portland cement is the best evidence of constancy of volume. The committee therefore concluded that accelerated tests are of no value in determining the durability of cements in practical use.

Report of the Committee on the Steinbruck Mortar-Mixer for Cement Testing.

It is well known that in the ordinary methods of mixing cement with sand and water for testing purposes the method followed and the personal equation of the operator are of great influence on the results. A widespread desire exists, therefore, for a more uniform mixing process. The apparatus which the committee consider the mixing-machine of the future is shown in the accompanying illustration.

The capacity of the apparatus is about 4 lbs. of mixture of cement 1, sand 3. The roller and plows may be easily and quickly removed for the purpose of emptying and cleaning the pan. Careful experiments have shown that no pulverization of the sand takes place during the operation. The gearing is so designed that 50 turns of the handle give 8 revolutions of the pan.



The Steinbruck Mixer for Preparing Mortar for Cement Test Briquettes.

Made by the Chemisches Laboratorium fur Thonindustrie, Berlin, Germany.

Tests of a slow-setting Portland cement gave the results shown in the following table. Each figure represents the average of 10 test-pieces:

	Tensile strength, lbs. per sq in.		
	Cement 1, sand 3.		
	7 days.	28 days.	90 days.
Hand mixing	278	349	438
Machine mixing—			
6 pan revolutions	266	356	434
8 " "	283	362	455
10 " "	273	361	468
15 " "	294	371	480
20 " "	302	403	452
30 " "	295	390	421
40 " "	319	386	471
50 " "	339	382	482
70 " "	330	395	519
100 " "	338	403	568

This table shows that about 8 revolutions of the pan are required to give the same results as those obtained by hand-mixing. The strength continues to increase greatly with increasing number of revolutions, and does not appear to have reached a maximum at 100 turns. It is to be expected that at a certain point the strength will begin to decrease in consequence of incipient setting of the mortar. Careful experiments to determine this point are now in progress, and tests thus far completed seem to indicate that a maximum is reached at about 150 revolutions.

The machine is arranged to be driven by hand or by power. When turned by hand it is found that a convenient speed is about 8 pan revolutions per minute. The apparatus in its improved form is now offered for sale by the Chemisches Laboratorium fur Thonindustrie, Berlin.

On the Action of Water Containing Carbonic Acid on Portland Cement.—In the report of the 1897 meeting a number of cases of corrosion of reservoir linings by carbonated water were mentioned. At the 1898 meeting Schiffner gave an account of an interesting series of experiments on this subject. Briquettes of the following mixtures were prepared:

Trass, 1; lime, 1; normal sand, 1.

Portland cement. 1; ground trass, 1; normal sand, 2.

Portland cement, 1; ground sand, 1; normal sand, 2.

The "ground trass" and "ground sand" had been pulverized to such fineness as to pass a sieve of 177 meshes to the linear inch.

These briquettes were kept in moist air one day, then in water in the laboratory three to six weeks. One-half of them were then placed in baskets and suspended in the water of the water-works spring at Bonn on the Rhine, while the remaining half remained in water in the laboratory. After 16 to 18 months the briquettes were inspected.

Those kept in the laboratory were found to be completely intact and well hardened, while those exposed to the action of the spring water showed more or less decrease in volume and strength. The reduction in volume was as follows:

Trass and lime	13.76%
Cement and ground trass	8.90%
Cement and ground sand	7.78%

The addition of trass appears, therefore, to have given no better results than that of fine sand.

Later tests with a mixture of Portland cement 1, normal sand 1, showed after three months' action of the spring water a loss in volume of only 1.77%.

Immersion of the briquettes in solutions of fluorides proved to diminish the corrosive effect of the water. The best result was obtained with lead fluoride. Briquettes of Portland cement with 3 parts normal sand were prepared, kept in moist air one day, then three times immersed, for 24 hours each, in a solution of lead fluoride, and dried. These were then placed in the spring water, and after 9½ months showed a loss in volume of only 0.06%.

The water supply at Bonn is obtained from a spring, and shows the following composition, in grams per liter (parts in 1,000):

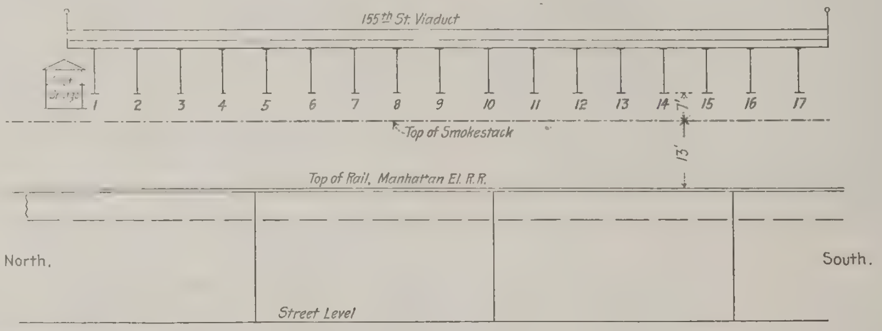
Sodium chloride	0.1246
" sulphate	0.0689
" bicarbonate	0.0477
Calcium carbonate	0.2400
Magnesium "	0.0605
Silica, iron oxide and alumina	0.0165
Organic matter	0.0043
Carbon dioxide, dissolved gas	0.3985

The water of the river Rhine at Bonn shows only ⅛ as much carbon dioxide and 1-14 as much sodium chloride as that contained in the spring-water.

TESTS OF VARIOUS PAINTS ON THE 155TH ST. VIADUCT, NEW YORK CITY.

In our issue of Sept. 23, 1897, the method of cleaning the iron work of this viaduct, as a preliminary to repainting the structure, was fully described. The cleaning was done by the Tilghman sand-blast process, the mixed air and sand striking the paint with a velocity of 250 to 300 ft. per second. Mr. M. E. Evans, the engineer in charge for the Department of Public Works, reported at the time that the surface of iron thus cleaned was exceedingly susceptible to rust, and if not at once covered with paint a few hours' exposure to ordinarily humid air resulted in a thin coating of red oxide. For this reason the work of cleaning and painting was carried on alternately each day, the sand-blast gang commencing operations at 6 A. M. and stopping at 3 P. M., when the painters at once began applying a priming coat and worked until 6 P. M., completely covering all of the surface cleaned that day. The paint used was supplied by seventeen different firms, each section being painted with a different paint. The paints were applied by workmen employed by the city.

As the painted surface is exposed to the gases from the locomotives of the Manhattan Elevated R. R., which pass directly under the structure, and as all the paints were applied to a clean iron surface, the comparative test is probably the fairest and most complete that has even been made of paints for the protection of iron work exposed to locomotive gases.



CROSS-SECTION OF 155TH ST. VIADUCT. SHOWING POSITION WITH RELATION TO MANHATTAN ELEVATED R. R.

A report upon the condition of these various paints has recently been made by Mr. Henry B. Seaman, M. Am. Soc. C. E., and we present it in full herewith as follows.

On April 12th, 1898, the writer made an examination of the different paints on that span of the 155th St. Viaduct which is directly over the tracks of the Manhattan Elevated Railroad at 8th Ave., and submits the following report:

This part of the bridge spans three tracks and two platforms, at the 155th St. station of the Elevated Railroad, and is composed of 17 lattice girders carrying floor beams upon which are riveted buckle plates, which in turn carry the roadway of the 155th St. Viaduct. These 17 girders are of 69 ft. span and 9 ft. in depth, being spaced 9 to 10 ft. apart, and having the bottom flanges about 7 ft. above the tops of the locomotive stacks. For convenient reference in this report, these girders are numbered from 1 to 17 consecutively, beginning at the north end.

A foot-bridge, located just north of girder No 1 also crosses above the tracks. The floor of this bridge is about 4 ft. below the bottom flange of girder No. 1 and about 3 ft. away from it in the clear. The 155th St. station being the terminus of the railway, the two outside tracks are in constant use by arriving and departing trains, while the middle track is used mainly by switching locomotives.

During the greater part of the day, trains arrive three minutes apart, alternating between the easterly and westerly tracks. The locomotives of the north-bound trains on the easterly track stop with the stack directly under girder No. 5, and remain about 20 seconds before hauling out. Incoming trains on the westerly track do not stop until the locomotive has passed north beyond the foot-bridge. All trains approach the station with steam shut off, except that used for brakes. It will thus be seen that the only girders which constantly receive the direct blast of the engine are girders No. 1 to 5 inclusive, the remaining girders receiving blasts only upon the occasional switching of engines, and in making up trains. In all other cases the girders are exposed alike to only such gases as the locomotives emit while the steam is shut off.

In making the examination, a careful general scrutiny was given to each girder from the platform below, and each was given a percentage mark, denoting the amount of surface free from rust. These percentages were then carefully compared and reviewed so that they might correctly represent the comparative condition of each girder. When these tests were completed, a thorough inspection was made by climbing through the structure and the character of rust was denoted for each girder. After completing the examination and recording the results, the kinds of paint used for each girder, with the number of coats and comparative rapidity of drying, were obtained from Mr. M. E. Evans, C. E., under whose direct supervision the girders were cleaned and the various paints were applied. The accompanying table gives the summary of the results:

Results of Tests of Paints on 155th St. Viaduct, New York City.

No. of girder.	Kind of paint.	Number of coats.	Rate of drying.	% free from rust.*
1	Lead, graphite and lucol oil.	3	Medium.	97[1]
2	Graphite and linseed oil.	2	Slow.	80[2]
3	Red lead, "Antoxide F," "Antoxide D."	2	Fast.	25[3]
4	Graphite.	2	Slow.	75[4]
5	"Nobrac."	3	Medium.	99[5]
6	"Carbon black."	2	Slow.	85[4]
7	"Durable metal coating."	2	Slow.	75[4]
8	"Black manganese iron."	2	Fast.	30[6]
9	"Carbonizing coating."	2	Slow.	80[1]
10	"Mineral rubber."	4	Fast.	78[7]
11	"Black."	2	Medium.	58[8]
12	Carbon.	2	Medium.	92[4]
13	Graphite.	2	Medium.	67[4]
14	Graphite.	2	Slow.	70[4]
15	Asphalt.	2	Very slow.	65[9]
16	"Ruberine."	2	Medium.	58[10]
17	"Black Diamond."	2	Medium.	70[11]

*Percentage of surface free from rust, April 12, 1898.

[1] Paint crumbling in places, as though rotten; very little rust.

[2] In fair condition, but discolored; rust coming through.

[3] Very badly rusted. [4] Rust not deep.

[5] Slight rust on top flange of one panel; rest of girder clear.

[6] Rust very deep; buckle plates bad.

[7] Area of rust spots small; rust very deep.

[8] Rust bad and deep.

[9] Deeply rusted; buckle plates still good.

[10] Rust deep and angry; buckle plates mildewed.

[11] Small pimples of rust, as though formed under paint.

It will be noticed, both by the percentage of clear surface and the character of rust on close examination, that girder No. 5 is preserved better than any of the set. When it is also considered that the priming coat of this girder was the one first applied, that it has been the most severely exposed to sulphur fumes, and that a portion of the priming coat was applied with the humidity averaging 96% for the day (where 100% is absolute saturation), the comparative condition in favor of girder No. 5 is very marked.

Respectfully,

Henry B. Seaman.

40 Wall St., New York city, May 24, 1898.

A FACTORY BUILDING OF STEEL AND GLASS.

The accompanying illustration is a view of a machine shop designed and built by the Berlin Iron Bridge Co., of East Berlin, Conn., for the Veeder Mfg. Co., of Hartford, Conn., the makers of the well-known Veeder cyclometer for bicycles. In the design of the building one of the principal ideas was that it should have an abundance of light on every square foot of floor space, so that it could all be available for carrying out the very fine operations required in the manufacture of cyclometers. The framework of the building is entirely of steel, the greater portion of the construction being steel and glass. It is three stories in height, 30 ft. in width, and 110 ft. in length, the three floors giving nearly 10,000 sq. ft. of floor surface. The glass sides of the building are arranged in sections, and every other panel swings on center pivots, so that they can be easily opened and closed. In warm weather, by opening enough of the panels to allow plenty of air to circulate, the interior may be kept as cool as that of any other kind of building under the same conditions of weather. The glass used in the sides is roughened or corrugated plate glass about ⅛-in. thick.

FACTORY OF THE VEEDER MFG. CO., HARTFORD, CONN.
Built by the Berlin Iron Bridge Co., East Berlin, Conn.

The floors are carried by girders spanning the entire width between the sides of the building, so that the floor space is entirely unobstructed by columns. The roof trusses are of sufficient strength to carry shafting, pulleys, hangers, etc., in addition to the roof load.

The heating of the building is done by the blower system, hot air being forced into the interior from an adjoining boiler-room. The air ducts are located in and made part of the supporting columns of the building. This feature was designed by Mr. C. H. Veeder, president of the Veeder Mfg. Co., and adopted by the Berlin Iron Bridge Co. in its design. The blower system may also be used for blowing cool air into the building in the summer.

An interesting question in relation to this building, on which we trust the Berlin Iron Bridge Co. may give us some information next year, is what will it cost to heat the building in cold weather? It is generally considered by heating and ventilating engineers that the emission of heat from glass surfaces is much greater than that from ordinary walls and roofs of buildings. If this is true, the heating of this building would be somewhat expensive. At any rate, the building offers a good chance to get some valuable data on the subject. We would suggest that an approximate idea of the cost of heating, independent of the power needed to circulate the warm air, could be obtained by measuring the drip from the air heating coils by means of a water meter. A reading of the meter taken every night and morning, together with the records of registering thermometers, one recording the temperature inside and the other that outside of the building, would furnish a set of data that should be of great value to heating and ventilating engineers and to mill architects.

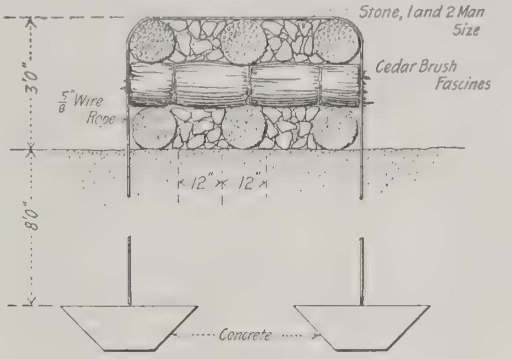
A NOVEL FIXED ANCHOR CONSTRUCTION FOR JETTIES, BUOYS AND LIGHT SHIPS.

We illustrate herewith a rather novel, and, according to all reports, a very efficient system of anchors employed in the construction of a small jetty built at Atlantic City, N. J., in 1897, to break the force of the waves, which were gradually tearing away the bathing beach and rendering it unfit for use. This jetty extends out from the shore a distance of 200 ft., and is built of cedar brush fascines, laid cob-house fashion, with the interstices filled with stone and anchored down to the sand bottom. Fig. 1 shows the arrangement of the fascines and anchor system in this jetty, and Fig. 2 shows the construction of the anchors proper in more detail. These anchors have been patented, the patent having relation to

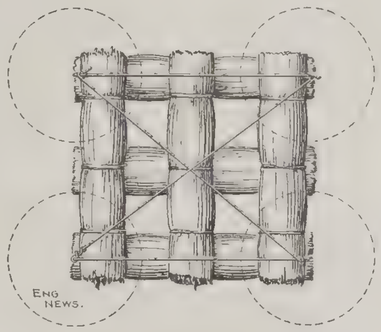
> anchors for securing jetties, buoys, piers, dykes, lightships, and like constructions which require permanent fixed anchors for holding them in position, and consists in the devices hereinafter described constructed to accomplish the ready sinking of the anchor and the retaining its desired position when sunk to the proper depth.

The inventor is Mrs. Gertrude Stuart Baillie, of Philadephia, Pa., and the use and sale of the system is controlled by the Sea Coast Jetty Co., 1420 Chestnut St., Philadelphia, Pa.

The construction of the Atlantic City jetty is shown very clearly by Fig. 1. The fascines were of cedar brush, bound by wire in the usual manner, and were 1 ft. in diameter. The bottom fascines were laid parallel to the longitudinal axis of the jetty 1 ft. apart in the clear. On the top of these came a layer of fascines laid at right angles to the first and 1 ft. apart, and finally another layer of longitudinal fascines laid like the first. The interstices between the three layers of fascines were filled with stone, and the whole was anchored down by a system of ⅝-in. wire cables attached to the special concrete anchors. The cost of the jetty was less than $10 per lineal foot.



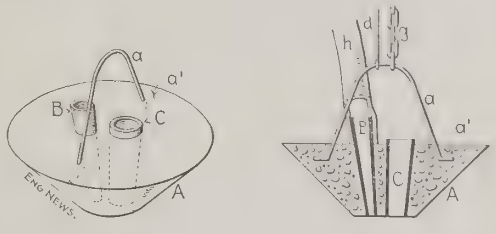
Elevation.



Plan.

Fig. 1.—Sketch Plan and Section Showing Construction and Anchorage of Jetty Breakwater at Atlantic City, N. J.

Turning now to the enlarged drawings of the anchor, A represents the main body of the anchor, which is made preferably of a wedge or cone-shape to allow it more readily to bury itself as the sand or earth is loosened or displaced from beneath it. In the upper portion of the body A is provided a staple a, secured from displacement by the hooked ends a' or by other suitable means. Perpendicularly through the anchor near the center is a pipe B, the upper end of which protrudes above the top of the anchor and is adapted to receive the end of a flexible water-supply pipe secured thereto by any desirable means, as by being stretched over the mouth of the pipe B. When the anchor is settled to its desired position, the flexible hose is pulled off or cut off at the water's edge, dropped, and thus disposed of. A waste-escape pipe C is also provided perpendicularly through the anchor adjacent to the water-supply pipe B.



View. Vertical Section.

Fig. 2.—Special Concrete Anchor for Atlantic City Breakwater, Showing Attachments for Water Jet Used in Sinking.

In operation the anchor, fitted with a lowering cord d and the securing chain attached to the staple a and with the supply-hose h properly attached to the pipe B, is dropped overboard at the desired point from a boat or platform. When bottom is reached, the water-supply from a pump or water-main is turned on. The force of the water as it is ejected from the lower end of the pipe-nozzle B at the bottom of the anchor forces away the sand or earth immediately below and about it. The weight of the anchor settles it in the cavity left by the displaced sand or earth. The stream continuing, the anchor buries itself gradually deeper, and so much of the escaping sand or earth which does not pass up along the sides of the anchor, as it settles, is forced up through the escape-pipe C and falls on top of the anchor, thus helping to bury it. The anchor keeps on descending and burying itself as the hose plays until the desired depth is reached, when the water is turned off and the flexible hose h is pulled off and abandoned.

When two anchors are desired for securing the object, such, for instance, as the Atlantic City jetty or a breakwater, a second anchor of like construction, with the other end of the chain g of the proper length attached to it, is in a similar manner dropped to its position and sunk to the desired depth by the same operation and the jetty firmly secured to the bottom, as illustrated. When the anchor is once in position, it is securely held by the sand or earth above and below it.

In constructing the Atlantic City jetty the anchors varied from 4 ft. to 3 ft. across the tops, the smaller sizes being used close to the shore, and they were sunk to a depth of about 7 ft. below the bottom. The material penetrated was sand, and after the water was turned on it took about 20 minutes to sink each anchor. For the information from which this description has been prepared we are indebted to the officers of the Sea Coast Jetty Co.

◆

THE ATLANTIC TRANSPORT LINE, largely an American corporation, has bought the fleet and business of the competing Wilson and Furness-Leyland Line, for about $5,000,000. Seven vessels are included in this purchase; all built within the past year or two and five of these are of 7,000 tons register. In addition to these the Atlantic Transport Line has five large cargo-carrying steamers built in England. These vessels will be 600 ft. long, 65 ft. beam, 44 ft. deep, with twin screws and engines capable of developing 16 knots. They will carry 300 first-class passengers, with 15,000 tons of freight and 1,500 cattle. This company sold all but two of its former fleet to the U. S. government a week ago for troop transports.

◆

AN ELECTRIC CANAL MOTOR is to be tested by Mr. W. G. Wagenhals, General Manager of the Cincinnati & Miami Valley Traction Co., on the line of the Miami & Erie Canal. He proposes to run upon an ordinary standard gage track, laid along the towpath, a specially designed electric motor car weighing about 30 tons. It will be driven by a 100-HP. motor geared for five different speeds, ranging from one-quarter mile to ten miles per hour. The motor will take current from an overhead wire about 12 ft. above the track. and an electric shoe will also take the current from a conduit when bridges or culverts prevent the use of the overhead wire. If successful 100 steel barges will be built to be towed by the motor cars, each of which is to be capable of hauling five heavily loaded barges. The trains of barges would be run on regular schedules.

◆

A MOTOR-SUSPENSION PATENT granted to Frank J. Sprague, Aug. 25, 1895, and now the property of the General Electric Co., has been sustained by a preliminary injunction issued by Judge Lacombe on June 21, against the Nassau Electric R. R. Co., of Brooklyn, N. Y. The motors were manufactured by the Steel Motor Co., of Johnstown, Pa. The injunction provides that within 30 days 250 motors must be removed; within 60 days 250 more; 250 within 90 days, and the balance in 120 days from date.

◆

AN ELECTRIC POWER AND TRANSMISSION PLANT, recently installed in Yuba county, Cal., and described in the "Journal of Electricity" for May, has a canal 23 miles long, with a section of 9 ft. and 5 ft. × 2½ ft. deep. The flume is built of timber, is 5 ft. × 3 ft. and 7⅞ miles long. The pipe line is 850 ft. long and gives an effective head of 292 ft. It is 42 ins. in diameter and made of steel varying from ⅛-in. to ¼-in. Three 40-in. Pelton impact wheels are used, each wheel having two 4-in. nozzles. The capacity of each is 700 HP., with a speed of 400 r. p.m. These are directly connected to Stanley two-phase generators of 360 K-W. at 2,400 volts and a periodicity of 8,000 per second; 12 Stanley transformers of 125 K-W. each, with a primary voltage of 2,400 and secondary voltage of 16,700 are used. One transmission line is 18¾ miles long, and the other 7¼ miles. Poles of 30, 35 and 40 ft. were used spaced 44 to the mile, with 3 × 4-in. × 5-ft. cross-arms, and pins 18 ins. apart. The No. 6 B. & S. medium-hard drawn copper wires are supported on 5½-in. triple-petticoat Locke insulators.

ELECTRIC TRACTION IN BERLIN, says the "Elektrotechnische Zeitschrift," for March 10, 1898, is somewhat behind the practice in other German cities. This is due to the importance of the interests involved, the difficulty of making arrangements and the prohibition of the overhead trolley system in the central parts of the city. In 1896 the Berlin Tramway Co. established a system which had an overhead trolley for part of the way and an electric conduit system for the remainder; and a similar line was built about the same time by Siemens & Halske. But there are many break-downs with the conduit system employed and the general results are unfavorable. On March 1, 1898, another line was established combining the overhead trolley and accumulators. The four-wheeled cars weigh 16 tons, and the battery weighs 2.6 tons and is supposed to store sufficient electric energy to make the round trip over the 10,725-ft. section of line thus operated. The cars are about 33 ft. long and seat 28 persons, with 12 places outside. It is proposed to thus transform all the tramway lines in Berlin within the next three or four years. The system is about 184 miles in extent, and 14% of this will be operated by accumulators, and the remainder by the overhead trolley.

◆

STREET RAILWAY FRANCHISES IN CHICAGO, according to resolutions adopted by the Chicago Federation of Labor, will not be acceptable "to wage-earners" hereafter unless they provide for 4-ct. fares, compensation to the city for the use of the streets, a 20-year limit to the life of the franchise, provision for the purchase of the system at the expiration of the franchise, eight hours as the maximum length of a working day for employees and freedom from persecution or discharge of employees on account of belonging to labor unions.

◆

A STEAM-MOTOR OMNIBUS, built by M. F. Weidknecht, of Paris, is described as follows: It is intended to carry 16 passengers, all inside, and about 1,000 lbs. of baggage. The main feature of the design is the concentration of all the power-generating plant and transmission gear in front of and entirely distinct from the body of the vehicle, and this mechanism is carried on two 4½-ft. wheels acting as drivers. This gives a practically constant load on the axle, and is intended to give increased adherence with less tendency to sliding on the pavement. The body is suspended by three plate springs on two wheels placed well toward the rear. The length of the omnibus over all is 18 ft., with 11 ft. in body; the distance between axle centers is 7 ft. 10 ins. In the motor section the frame is made of light channel iron, to which the boiler, tank, etc., are riveted. The boiler is of the vertical multiple tubular type, with a super-heater, and a heating surface of 64.56 sq. ft. Coke is used for fuel and there is an automatic stoker attachment. The engine has two 4.9-in. cylinders, and develops about 20 HP. The power is transmitted from the main shaft of the engine, through gear wheels, to an intermediate shaft, and from the latter to the front axle by the usual chain and sprocket wheel. The two rates of speed provided for are 4.6 and 9.3 miles per hour, at 350 engine revolutions per minute. By regulating the admission of steam the speed may be run up to 12½ miles per hour. A band foot-brake, on the rear wheels, and a hand screw-brake, on the driving wheels, are provided. Tests have been made showing a consumption of about 14 lbs. of coke per mile run on ordinary roads; though it is claimed that this can be reduced to 10.7 lbs. on good level roads. The weight of the omnibus is 4 tons 14 cwt. empty, and about 7 tons loaded.

◆

AN ELEVATOR SHAFT to the summit of Mont Blanc, with a shaft 1½ miles deep and a 3½ mile tunnel to the bottom of the shaft, is proposed by a French engineer, Paul Issartier, of Marseilles. The tunnel would rise 600 ft. in 18,864 ft., terminating 7,500 ft. above sea-level. The vertical shaft would be 10 × 13 ft., and have a depth of 8,200 ft., and he proposes to excavate it from below. He has devised a "rising chamber," made of strong steel plates, in two stories divided by steel doors; on the upper floor would be the rock-drilling machinery, driven by compressed air. To avoid lowering the "chamber" out of the way of blasts, he would drill only on one side first, then roll the drilling machines to the other side and protect them by lifting steel doors. To catch the fragments of rock he proposes a series of strong steel gratings, placed at an angle of 45° and protected by fascines; these are supposed to permit the passage of the gases of explosives while retaining all the rock. On the lower story this rock would be "pulverized" and then passed down a 12-in. tube to the bottom of the shaft, and thence carried outside by a stream of water propelled by centrifugal pumps. The "chamber" would rest upon and be raised by strong steel racks placed in the four corners of the shaft. He presents no estimate of cost, and the proposition is chiefly interesting as a somewhat wild attempt to solve some novel engineering problems.

◆

SIAMESE RAILWAYS, says "Indian Engineering," include the following, as the only lines in existence at present: The 13-mile line from Bangkok to Paknam, owned by a Danish company, and 87 miles of the line northward to Ayuthia. The latter line is to be extended to Khorax and will then be 164 miles long. A concession to a Danish company proposes another railway about 140 miles long, extending from Bangkok to Phetchabouri; but the most important line proposed is the extension of the Bangkok-Ayuthia railway northward 310 miles in a direct line to Zimme (Chiengmai).

◆

BERLIN STREET PAVEMENTS, says Consul-General Goldschmidt, in answer to queries, had an area of 6,500,405 sq. yds. on March 30, 1898. Of this area a little less than 74% is stone pavement; about 25% is asphalt and a little over 1% is wood. The use of asphalt is steadily increasing. The subsoil is a coarse, gritty sand, and forms an excellent foundation for the 8-in. concrete course underlying the 2-in. asphalt pavement. The average price for asphalt pavement in Berlin is $2.80 per sq. yd.; the contracts for laying the pavements run for 20 years, and the contractor keeps them in repair for five years free of cost to the city, and thereafter receives 10 cts. per sq. yd. per year for this service.

◆

PHILADELPHIA'S AVERAGE DAILY WATER CONsumption for 1897 was 187 gallons per capita, with an estimated population of 1,385,734. In 1887 the consumption per capita was 89 gallons, the increase in ten years being more than 100%. The Chief of the Water Bureau, Mr. John C. Trautwine, Jr., very properly remarks that no one will pretend to believe that this 187 gallons per head per day represents water legitimately used for household or manufacturing purposes. It is simply, in great part, a waste of water that costs the city $3.16 per million gallons pumped 100 ft. high, and every gallon consumed in that city is pumped. For some reason, meter service is not regarded with favor in that city; though the application of some such check upon waste would seem to be largely demanded, and it would certainly be profitable to the city. There is evidently no lack of water, such as it is, and the recommendation to purify the supply by sand filters should be supplemented by the adoption of means to stop the needless waste of water.

◆

CAST-IRON WATER PIPE at $16.60 per net ton delivered in Boston seems to be a record low price. The Warren Foundry & Machine Co., of Phillipsburg, N. J., lately made a contract with the Metropolitan Water Board to deliver 937 tons of 12 to 36-in. pipe at that price; the pipe to be delivered at Brighton, Forest Hills, Glenwood and Clinton, on the line of the new Metropolitan Water Supply. Nearly one-half the pipe ranged in diameter from 30 to 36 ins. We believe the transportation cost on the contract will be about $3 per ton, making the actual price received for the pipe at the foundry little more than $13.

◆

THE STATUS OF THE SEPTIC TANK SYSTEM of sewage treatment, so far as the Local Government Board of England is concerned, has been made known by the action of the board in the Exeter case. In our issue of Jan. 13, 1898, we described the septic tank, including the trial and proposed plant at Exeter, England. The board has approved the loan necessary to carry out the scheme, but the approval is conditioned on the understanding that if the system is unsatisfactory the city will substitute some plan of chemical precipitation and artificial filtration, and also that the city will, at the start, supplement the septic tank system with land treatment exactly as would be required in the case of chemical precipitation; that is, provide one acre of filtration area for each 2,000 population. We are indebted to the London "Surveyor" for the above information.

◆

ANOTHER SUCCESSFUL WAVE MOTOR PUMP is reported from California. It has been built by William and Edward Armstrong at Santa Cruz, Cal. From descriptions given in the Santa Cruz "Sentinel" and "Surf," it appears that the apparatus consists of a well 6 ft. diameter and 40 ft. deep, sunk in the rock a short distance from the water's edge, the bottom of the well being connected by a 6-ft. tunnel with the open sea, a float weighing about 800 lbs., which rises and falls in the well with the movement of the ocean wave, and a 6-in. direct-acting pump, whose plunger is operated by the motion of the float. The work now done by the motor is the spouting of a jet of water from a 2-in. hose pipe to a height of 50 to 100 ft. above the level of the cliff.

◆

THE UNITED STATES AT THE PARIS EXPOSITION of 1900 is especially reported upon by Mr. Thomas W. Cridler, Third Assistant Secretary of State. and the successor of the late Moses P. Handy as Special Commissioner of the United States for the Exposition. Mr. Cridler's report is published as Senate Document No. 293 for the 2d Session of the 55th Congress. It contains his report upon the progress of the Exposition buildings and detailed plans and elevations of the spaces allotted to the United States in the several buildings. Mr. Cridler earnestly recommends, for commercial reasons, a full and representative exhibit by the people of the United States.

Note on the Behavior of Some Cements with Dilute Hydrochloric Acids—The Effect of Temperature on the Flow of Water Through Soils.

THE JAPANESE PROTECTED CRUISER "KASAGI," built at the Cramp's shipyards in Philadelphia, had her contract trial trip on July 12, and with rough water and a strong tide setting almost at right angles with the course, a mean average speed of 22.75 knots per hour was developed. The course was 20 miles long, in four legs, and the following table shows the results of the run up and down the course, a total of 40 miles:

Run up.	Elapsed time. min. sec.	Speed. Knots.
First lap	12:54	23.25
Second lap	13:07	22.90
Third lap	13:00	23.07
Fourth lap	13:00	23.07
Total interval, 52:09. Average, 23 knots.		
Run down.		
First lap	13:14½	22.65
Second lap	13:14	22.67
Third lap	13:33	22.12
Fourth lap	13:19	22.55

Total intervals, 53:20. An average of 22½ knots. Mean speed for the run, 22.75 knots.

The revolutions rose from 158 at the beginning of the run to 164 at the end. To show the perfect condition of the machinery a series of progressive trials was run as soon as the main trial was over, in order to get the speed at 80, 125, 150 and 162 revolutions. The "Kasagi" is 374 ft. long and 48 ft. beam, and is one of the heaviest armed cruisers of her size afloat. She will carry two 8-in. breech-loading rifles and ten 4.7-in. rapid-fire guns. The vessel was completed six months ahead of the contract time.

◆

THE LAKE STEAMER "HENDRICK S. HOLDEN" was launched at the yard of the Globe Iron Works Co., of Cleveland, O., on June 25. This vessel is 430 ft. long and 410 ft. keel, 50 ft. beam and 28 ft. deep. The hull is built of mild steel and her masts are also steel; she has twelve cargo hatches spaced 24 ft. between centers. Her quadruple expansion engine has 20¼, 30¼, 44 and 63½-in. cylinders with 42-in. stroke. The three Scotch boilers supply steam at 230 lbs. working pressure, and these boilers are fitted with the Ellis & Eaves system of induced draft. The carrying capacity of the vessel is 5,500 tons.

◆

BROOKLYN DRY-DOCK NO. 3 has been officially declared safe and ready for use by Mr. P. C. Asserson, C. E., U. S. N., in charge of the Brooklyn Navy Yard. Naval Constructor F. T. Bowles, U. S. N., in charge of the repairs, is now relieved from further responsibility. The coffer-dam at the entrance has yet to be removed, and the entrance will then be dredged out to the full depth.

◆

THE LAKES ST. CLAIR AND ERIE SHIP CANAL project, says the New York "Sun," is again attracting attention, and there is a prospect that active work may be commenced upon it within a year. The line of the canal, commencing in the channel in Lake St. Clair and about 5 miles from the head of the Detroit River, would pass 17½ miles over the "Flats" to the shore line; the actual cutting across the neck of land to Lake Erie is about 14 miles, and the mouth of the canal on the latter lake would be about 60 miles easterly of the usual route through the Detroit River, with an actual saving in distance of 79 miles. The estimated cost of the canal is $5,500,000, and it could be built in two years. The promoters figure that a toll of 3 cts. per ton would be sufficient to make the enterprise a paying one, provided two-thirds of the tonnage now passing Detroit could be deflected to the new route.

◆

THE MISSISSIPPI RIVER COMMISSION has made the following allotments for levee work, according to the Memphis "Commercial": Tensas District. $100,000; St. Francis Levee District, $34,000; the Upper Yazoo, $26,000; Lower Yazoo, $90,000. This latter is Major Wm. Starling's district.

◆

THE MOST SERIOUS RAILWAY ACCIDENT of the week was a freight train collision on the Pittsburg & Connellsville line of the Baltimore & Ohio R. R., at Foley's, Pa., on July 9, in which one man was killed and six were injured. The accident was a head-end collision and. it is stated, was due to an error in the train orders. ——The collision of a freight train with a switching engine in the yards of the Pittsburg & Lake Erie R. R., near Pittsburg, Pa., on July 7, resulted in the serious injury of one man, the destruction of several freight cars, and considerable injury to the colliding locomotives.——A derailment at Ridgewood, N. J., on the Erie R. R. on July 9 resulted in injuries to the fireman and engineer and wrecked 26 freight cars. A westbound freight train was pulling out onto the main line at high speed when the locomotive jumped the frog, owing, it is thought, to the spreading of the rails. The cars crashed into the engine and were thrown from the track.

◆

THE BROOKLYN BRIDGE TROLLEY SERVICE was blocked for 30 minutes on July 9, owing to the burning of one of the switch boxes used to control the power on the bridge by a stroke of lightning which grounded the wires. The box is of wood, about 2 × 3 ft. in size, and contains four switch levers, which connect or disconnect the current to different portions of the bridge. The explanation of the engineers is that lightning striking the electric wire on the bridge grounded the current, and formed an arc in the switch box, which destroyed it. The damage was intensified by the attempt to counteract the grounding by sending the full force of the current from the power house through the switch box.

◆

AN EXPLOSION AT THE LAFLIN-RAND POWDER Works, at Pompton Lake, N. J., on July 9, caused the death of nine and perhaps of eleven persons, and wounded a number of others, besides destroying property amounting to about $30,000. Nine buildings were destroyed, including two mixing-houses, two guncotton-houses, the assembling-room, two traverses and the boiler and powder houses, the latter two being destroyed by fire. The first explosion, there being two, started in the northern mixing-house. In the mixing-rooms is a combination of guncotton, glycerine and nitric acid in process of manufacture. To the east of the mixing-rooms is a stone wall, 10 ft. high and 4 ft. thick, with an opening at about the center, through which the workers disappear and take refuge behind the stone wall when the machinery in the mixing-room is started. The men return to work after the machinery is started, and it was at this juncture, it is thought, that the explosion occurred. Captain Aspinwall, the Superintendent of the works, states that the mills will be delayed about two months in their orders. There were 60,000 lbs. of powder on the ground ready for shipment to the army when the accident occurred, but luckily this was not injured. Of the 47 buildings on the premises 38 are intact. The door of a building containing the store of guncotton was blown off, but the high explosive remained unharmed. An investigation has been commenced to determine the cause of the explosion.

◆

FIRE DESTROYED THE STEAMER "DELAWARE," of the Clyde Line, off Barnegat, N. J., on the morning of July 9. All the passengers, 66 in number, including the crew, were saved by taking to the boats. The "Delaware" was a wooden vessel and was 19 years old. It is supposed that the fire started in a quantity of wood stored under the main saloon deck. When discovered the flames had gained so much headway that all attempts to put out the fire were found to be useless, and the whole attention of the ship's crew was turned toward saving the lives of the persons on board. The ship, which was some 10 miles from shore when the fire was discovered, was run in to within about 2 miles of the shore, and the passengers and crew transferred to the ship's boats, from which they were taken by the tug "Ocean King" to New York. Wrecking tugs, which were sent to the scene of the accident at once, attempted to tow the burned hull to New York, but after proceeding a short distance the hull sank off Point Pleasant, N. J.

◆

A STREET CAR COLLISION in Washington, D. C., on July 10, resulted in the death of one and the injury of nearly 30 persons. The accident occurred opposite St. Elizabeth's Government Asylum for the Insane. A steep hill runs from the asylum into Anacostia, and the brake chain broke as the car started to make the descent. The motorman jumped without reversing his motor, and when the car reached the bottom of the hill it had gained a speed, it is stated, of 70 miles an hour. The horse car was standing on the turntable at the end of the line, and the driver jumped just in time to save his life. Many of the passengers were injured by jumping from the car during its flight down the hill.

◆

A BROKEN PISTON ROD on the steamer "Lucania," of the Cunard Line, compelled that vessel to enter Liverpool on her last trip under one engine. The rod which broke belonged to the port engine, and the accident occurred on July 7. The passengers were in bed at the time and did not know of the accident.

◆

THE STEEL INTAKE CRIB for the new intake tunnel of the Cleveland water-works was towed to place and sunk in position on July 1. The crib has an exterior diameter of 100 ft. and was sunk in nearly 50 ft. of water at a point some four miles from the shore. The inner wall of the crib forms a well 50 ft. in diameter. Between the inner and outer walls are water-tight bulkheads, 24 in number. The plates for both walls and the bulkheads are of ⅜-in. steel plates. The compartments will be filled with stone. The contractor for the crib is the Van Dorn Iron Works, of Cleveland. Mr. M. W. Kingsley, M. Am. Soc. C. E., is superintendent of the water-works and chief engineer of the new tunnel. Mr. C. F. Schulz is first assistant engineer of the water department.

◆

ANOTHER ACCIDENT IN THE CLEVELAND WATER-works tunnel occurred on the evening of July 11, in which ten or eleven men are supposed to have lost their lives through a gas explosion. The men were at work under air pressure some 6,500 ft. from the shore shaft and just beyond the scene of an explosion that occurred on May 11, which caused the death of eight men.

◆

STREET CAR FENDERS are to be used in Chicago if the new ordinance passed July 5 is carried into effect. Similar ordinances have been passed, but have been declared void by the courts to which the street railway companies appealed for relief. The present ordinance provides for fenders of the basket type, built of steel. Some of the companies' officials claim that the transverse plank in front of the wheels is all that is necessary and that basket fenders will be a constant source of danger.

◆

PLANS AND ESTIMATES for a filtration plant for Philadelphia, to be made by the department of public works, and to be ready by Oct. 1, were ordered by the lower branch of the city council on July 11. The same body has indefinitely postponed consideration of an ordinance providing for the construction of a filtration plant.

◆

THE FILTRATION OF THE WATER SUPPLY of Providence, R. I., is again under consideration by the city council, after having been dropped for a number of years. A review of the several plans for filtration and a critical abstract of a report by Mr. Edmund B. Weston, M. Am. Soc. C. E., Assistant Engineeer in Charge of the Water Department, was published in Engineering News for April 16, 1896.

◆

THE BROAD ST. BRIDGE, over the Phila. & Reading Railway subway in Philadelphia, was opened to traffic on July 2. This bridge is 113 ft. wide, with 69 ft. in the driveway and two 22-ft. sidewalks. It is carried over the depressed tracks by a steel plate-girder structure of five spans, having a total length of 265 ft. and containing over 1,000 tons of steel. This bridge also carries beneath its floor five lines of 12-in. gas mains and 36 galvanized iron pipes carrying electric cables. The bridge was built in sections, the first half being commenced on Dec. 30, 1897, and that part was opened to travel on April 14, 1898. The other half was commenced on April 21, and completed as above.

◆

THE FIRST IRON BRIDGE IN OHIO was erected in 1851, on the Central Ohio Division of the Baltimore & Ohio Railway, over Salt Creek, in Muskingum County. It was a single span Bollman deck truss of 71 ft. Mr. Bollman was at that time Chief Engineer of Construction on the B. & O. Railway. This bridge, after 47 years' service, has just been removed.

◆

A PILE-DRIVING RECORD is reported from Manitowoc, Wis., where Mathews & Keith, contractors of that city, are building a grain elevator for the Northern Grain Co., of Chicago. On June 22, pile-driver No. 5 drove 151 piles in ten hours, and pile-driver No. 4 drove 140 piles in the same time. These piles were from 20 to 24 ft. long, and they were driven from 18 to 20 ft. into the ground to a hardpan stratum. The pile drivers were specially designed by the above firm and have a 5,000-lb. hammer, operated by 30-in. double drums and a 30-HP. engine. Similar drivers were used at Buffalo, N. Y., in putting in the foundations for the Great Northern Steel grain elevator.

THE SINKING OF A STEAMSHIP AT SEA.

Mr. Cecil Lightfoot, of the Lynde British Refrigeration Co., has furnished to several of the English illustrated journals an account of the foundering of the Japanese steamship "Tai Hoku," in the Atlantic Ocean, August, 1897, on her maiden trip to Osaka. The photographic views taken ot the sinking of the steamer are the interesting features, and we here reproduce three of them from the "Indian and Eastern Engineer."

The "Tai Hoku" was a steamer of 3,100 tons, built at Middleboro, England, for the Osaka Steam Navigation Co., and she was fitted with a refrigerating plant by the company with which Mr. Lightfoot was connected. Having sailed to Antwerp to complete her cargo, the steamer left that port on Aug. 6, 1897, for Japan. On the following Sunday she passed into a heavy fog bank, off Cape Raso, and at about 9 p. m. the steamer collided violently with another vessel. At first it was supposed that no serious damage had been done; but in half an hour 5 ft. of water was reported in the forehold. The water gained at the rate of about 2 ft. per hour, and the ship gradually settled by the head.

At 4 a. m., on Monday, there were 16 ft. of water in the forehold, and all the pumping power available made no impression upon the inflow. At 5 a. m. all hands took to the boats and pushed off a few hundred yards from the sinking steamer; and at 8.30 a. m. the party was rescued by the steamer "Millfield." By this time the fog had cleared away, and the stern of the "Tai Hoku" could be seen gradually rising in the air. Shortly before 1 p. m. she began to roll heavily and then she plunged and sunk. In the 15 minutes previous to her final disappearance four photographs were taken; of which three are here reproduced.

When the "Tai Hoku" went down, there was, of course, considerable steam pressure in her boilers, possibly 60 or 70 lbs. When the bridge collapsed, the siren and fog-horn cords being attached to it, both the siren and fog-horn sounded, just as the vessel disappeared. The third and final view shows, apparently, an explosion. But, as a matter of fact, says Mr. Lightfoot, there is little doubt that when the water reached the boiler flues there was a sudden generation of steam and gas, which rushed with almost an explosive effect up the flues and smoke-stack, carrying with it quantities of soot which remained suspended in the air for some minutes after the ship disappeared. There was not the least sign of the proverbial whirlpool when the ship went down, though there were abundant surface signs of the gradual escape of the air imprisoned in the hull.

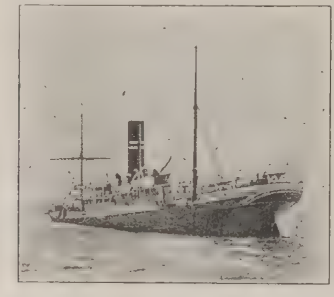

Fig. 1.—Fifteen Minutes Before Sinking.

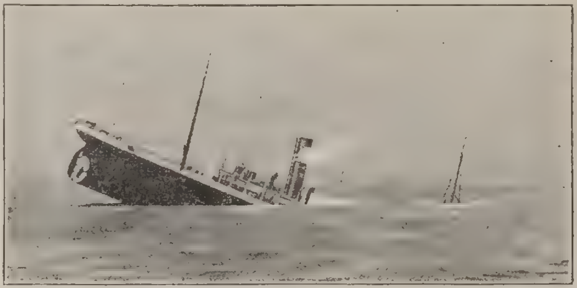

Fig. 2.—Five Minutes Before Sinking.

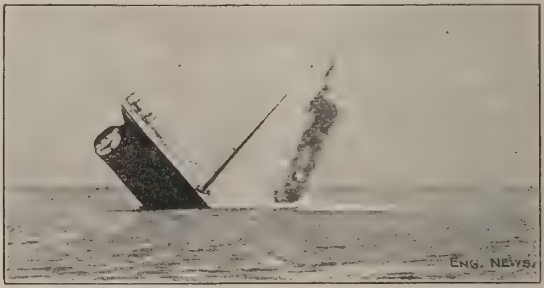

Fig. 3.—The Final Plunge.

THE SINKING OF THE STEAMER "TAI HOKU" OFF CAPE PASO, FRANCE, AUGUST, 1897.

THE STEEL DOME FOR THE YERKES OBSERVATORY, LAKE GENEVA, WIS.

(With two-page plate.)

Those of our readers who saw the model of the great Yerkes telescope intended for the University of Chicago, as it stood in the Manufactures' Building, at the World's Columbian Exposition, have doubtless often speculated regarding the future home and work of this remarkable instrument as their eyes have caught from time to time the newspaper reports concerning the progress of work upon the 40-in. objective lens and other parts of the elaborate machinery. The Yerkes telescope, as is quite generally known, is the largest refracting telescope in the world, its object glass being 4 ins. greater in diameter than that of the Lick Observatory telescope at Mt. Hamilton, California, and it is needless to say that astronomers expect much usefulness from it in the particular line of astronomical research to which it is to be applied. Besides being of especial interest to the astronomical world, however, the great refractor is of great interest to the mechanical and structural engineer, for the skill of both has been called into service in designing its ponderous and delicate operating machinery and the building which it is to occupy. From information furnished by the astronomical department of the University of Chicago and by the engineers and contractors who designed and built the observatory dome and its operating machinery, we present here a pretty complete description of the features of particular interest to engineers:

The observatory building, in which the great telescope has been installed, is located at Lake Geneva, Wis., and, like the telescope, was presented to the University of Chicago by Mr. Charles T. Yerkes, of Chicago, Ill. Its general appearance is pretty clearly shown by Fig. 1, which is from a photograph taken before the covering had been placed on the main dome, and before the steelwork of the two smaller domes had been erected. The form of the building, as will be observed, is that of a Latin cross, with the three towers or domes at the extremities. The long axis of the building runs east and west, and is 326 ft. in length. The large dome which contains the 40-in. telescope is at the western extremity and is 90 ft. in diameter. The building is constructed of brown Roman brick with terra cotta ornaments of the same color. The credit of the architectural design is due to Mr. Henry Ives Cobb, of Chicago, Ill., but the general form of the building and its interior arrangements were determined by Prof. Geo. E. Hale, the Director of the Yerkes Observatory.

The chief interest of the observatory from an engineering standpoint lies in the main dome, and its operating machinery, but a brief statement may be made of some of the minor features of construction and equipment. The northeast tower or dome will contain a 12-in. telescope now located at the Kenwood Observatory of the University of Chicago, and is 30 ft. in diameter. The southeast tower is also 30 ft. in diameter and will contain a 16-in. telescope. Between the three towers the space on the two floors of the building will be occupied by a meridian room, a heliostat room, spectroscopic and chemical laboratories, instrument and computing rooms, library, instrument and optical shops, and numerous smaller rooms for different special operations connected with the work of the observatory. A power-house for supplying the necessary power for the various machines is located about 750 ft. from the large dome of the observatory, and is equipped with two 8×10 ins. Ideal engines, each operating a Seimens-Halske dynamo, with a capacity of 200 amperes at 125 volts.

The main tower, in which the 40-in. telescope is located, may, for the purpose of this description, be divided into the revolving dome, the rising floor, the operating machinery and the telescope proper. The circular wall of the tower terminates at a height of 52 ft., and is surmounted by a dome 90 ft. in diameter and 60 ft. high, which revolves on a circular track on the tower walls. Figs. 2 and 3 show a plan and vertical section of the steelwork for the dome. As will be seen the framework is composed of two main girders or arches, standing on each side of the observing slit, and 18 secondary arches, all of lattice girder construction. These main members carry lattice purlins, which act as sway frames, and also jack rafters of channels, which support the sheathing. This sheathing is 1-in. matched pine, covered with tin, the whole idea being, of course, to make the structure as light as possible, since it has to be revolved around to accommodate the telescope.

The principal difficulties in the designing, it will be seen, were, first, that a clear opening, 12 ft. wide, had to be left in the dome from about the horizontal to 6 ft. beyond the vertical, and, second, no ties were possible across the bottom to hold the feet of the arches together. The second of these difficulties was overcome by constructing a heavy circular lattice girder around the rim, to which the feet of the arches were attached. To provide against the first difficulty the strength and rigidity of the main arches had to be depended upon. The opening for the telescope or observing slit, was covered by two shutters, each made up of two curved plate girders, braced together by angle iron bracing and resting on rollers at the top and bottom. These shutters roll each way from the center of the slit to allow for the necessary opening. Besides the regular shutters for covering the opening it was necessary to provide for a light canvas curtain to cover the slit, when the shutters were rolled back, with the exception of what little space was needed for the end of the telescope. This was accomplished by having a track below the girders carry a little carriage on which the canvas curtain rolled.

As previously stated the dome revolves on a circular track, carried by the tower walls. Fig. 4 shows the construction of this track and of the weather guards at the outer edge of the tower wall. As will be seen, the track consists simply of an 85-lb. T-rail resting on a cast-iron girder bolted to the masonry. This girder was laid in sections 7 ft. 3 58-64 ins. long, or eleven sections, each 30° of arc. Twenty-two cast-steel wheels, 36 ins. in diameter carry the dome on the circular track. The journals carrying these wheels are fitted with roller bearings and are so mounted that the wheels are left free to adapt themselves to any possible inequalities of track.

The object of the rising floor was to render the eye-piece of the telescope equally accessible to the observer at all positions of the instrument. Briefly described, this is a circular floor, 75 ft. in diameter, which is so supported and counterbalanced that it can be made to rise and fall vertically through a distance of 23 ft. A balcony around the inner wall of the tower at each extremity of the travel of the floor gives access to it at these points, while at intermediate points of its travel it is entered from two stairways which connect the two balconies. Figs. 3, 5 and 6 show pretty clearly the general construction of the rising floor, and also several details of the dome construction not shown by the previous illustrations. As will be noticed, an opening is left in the rising floor for the standard supporting the telescope. In construction the floor consists of lattice girders, thoroughly braced, and carrying steel joists, which are covered with a wood floor. The total weight of the rising floor is 37.5 tons.

The machinery for rotating the dome and operating the rising floor is located in the basement, and consists of both hand and power machinery for each duty. To rotate the dome an endless wire cable passes around an angle fastened to the inside of the dome at the bottom. This cable coming from opposite directions passes over two vertical idlers, thence down and around a vertical operating sheave, thence around a tension pulley. The operating sheave is geared with an electric motor or with a hand operating device, as may be desired. An endless hand rope also runs from the sheave in the basement to one on the upper balcony, which allows the dome to be turned from either balcony or any intermediate point between them. The method of operation, it will be seen, is quite simple; the wire cable runs entirely around the dome horizontally, as if it were a large drum, and is held taut by the tension weight, while the operating sheaves give it the required motion. To raise and lower the rising floor four rope drums are placed, as shown by Fig. 7, and operated by worm gears on shafts radiating from a central motor. These drums are place 90° apart, where the columns, which guide the counterweights, are also placed. At each column is a wire cable which is attached to the top of the floor and thence passes to and over a sheave, and has its opposite end fastened to the counterweight. From the bottom of the counterweight another cable passes to and around the drum in the basement and thence to an attachment on the bottom of the floor. The floor and counterweight thus form links in an endless cable, whose movement is controlled by the operating drum.

From the foregoing the construction and operation of the 90-ft. dome will be pretty clear. As will be imagined, the erection of the various parts required great care and skill, particularly as the height of the top of the dome from the ground was 115 ft., and as severe storms arise with great suddenness in this region. The framework being mounted on wheels and also being very light, the effect of a sudden heavy wind storm upon the partly connected members was very likely to be disastrous. No accident with the dome proper occurred, however, with the method adopted, which is illustrated in the accompanying cuts.

A derrick was first erected on the brick foundation for the telescope, which was at the center of the tower. The mast of this derrick was about 50 ft. high and the boom 110 ft. long, or long enough to cover the top of the circular tower wall with ease. With this derrick the circular track and the greater part of the dome framing was placed. The first thing done was to erect the two main arches. These being too large to be raised entire inside the tower, the middle section, 35 ft. long, of each was first raised and then the two end sections were raised and connected with it. The feet of the arch were then sprung out to their positions on the circular track. Fig. 8 shows the main arches erected and one-half each of three of the smaller arches connected with them. All the smaller arches were assembled on the ground inside the building, and the halves raised complete with the wheels attached, Fig. 9. The purlins, horizontal girder and bracing between the arches were connected as fast as the arches were placed, Fig. 10 shows the dome framework practically complete, and the shutters in the process of erection. Following the completion of the dome, the standard carrying the telescope was erected, and, finally, the telescope, tube, rising floor, and minor structures put in place. This completed the main structural work of the dome and tower.

It will not be out of place in connection with the foregoing to say a few words regarding the great telescope for which the structures described have been constructed, and through the courtesy of Prof. Geo. E. Hale, Director of the Yerkes Observatory, we have been furnished with the following description:

> Representing as it does an increase in aperture of but 4 ins. over the largest equatorial refractor hitherto constructed, the Yerkes telescope might not at first sight be supposed to offer any special difficulties of construction or design. As a matter of fact, however, the problem of designing a suitable mounting for the 40-in. objective was by no means a simple one. The great weight of the objective, about 1,000 lbs. in its cell, and the desirability of attaching an equally heavy spectroscope at the eye-end made necessary the construction of a tube of exceptional rigidity. The consequent great weight of the moving parts must inevitably increase the difficulty of moving the telescope, and for this and other reasons it was decided to provide a complete system of electric motors and clamps, for the purpose of effecting the various operations usually performed by hand. It will thus be seen that the greatest experience and skill would be required of the designer of a really successful mounting.
>
> After carefully examining most of the great telescopes in American and European observatories, the writer decided to recommend to Mr. Yerkes that the contract for the mounting be awarded to Messrs. Warner & Swasey, not only because of the well-known excellence of their workmanship, but more especially on account of the invaluable experience gained by this firm in designing and constructing the mounting of the 36-in. Lick refractor.
>
> The cast-iron column consists of four sections, tapering from 11 × 5 ft. at the base to 10 × 5 ft. at the junction with the head. These four sections are bolted together, and rest on a cast-iron foot which is firmly anchored to a massive brick pier supported on a concrete foundation 32 × 28 × 5 ft. At the top of the column is the equatorial head, which is cast in a single piece. The column and head rise to a height of 43 ft. above the lowest position of the rising floor, and weigh 50 tons. Surrounding the head is an iron balcony, accessible from the rising floor by means of a spiral stairway on the south side of the column, which also leads to the clock room in the upper section of the head.
>
> The polar and declination axes are of hard forged steel, and weigh 3½ and 1½ tons respectively. The polar axis, 13½ ft. long, has a diameter of 15 ins. at the upper bearing and 12 ins. at the lower bearing. At both of these points the friction is relieved by means of live rings of steel rolls, running in steel yokes, and held against the axis by spring levers. The lower end of the axis rests on a double set of 40 hardened steel balls, 1 in. in diameter. The upper end carries the main driving gear, which has 330 teeth, is 8 ft. in diameter, and weighs one ton. This is driven by a worm geared to the driving clock, and when clamped to the axis sets in motion a mass weighing 20 tons.
>
> The declination axis which runs in Babbitt bearings in the declination sleeve is 12 ins. in diameter and 11½ ft. long. The pressure of this axis upon its bearings, amounting, with the weight of the tube, to about 8 tons, is relieved by a live ring of steel rolls, which greatly reduces the friction.
>
> The tube is made of sheet steel, varying in thickness from 7-32-in. at the center to ⅛-in. at the ends. Its diameter is 52 ins. at the center, 42 ins. at the objective end and 38 ins. at the eye end. It is 60 ft. long, and weighs 6 tons. For the central station, to which the declination axis is bolted, it was considered necessary to use some material more reliable than cast-iron, which is ordinarily employed in smaller mountings. The heavy sheet steel selected for this purpose seems to be in all respects satisfactory.
>
> The driving clock stands in the clock room in the upper section of the column, where it is easily reached from the spiral stairway. The double conical pendulum, mounted isochronously, makes sixty revolutions per minute. It is provided with a simple electric control. An electric motor automatically winds the clock when the driving weight has reached a point near the limit of its run.
>
> The telescope is so designed that it would be in perfect balance with the spectroscope weighing about ½ ton attached to the eye end. When the spectroscope is removed iron weights are clamped to the tube near the eye end in order to restore the balance.
>
> The clamps and slow motion can be operated by the observer at the eye end, where the fine declination circle can also be read. An assistant on the balcony can move the telescope in both right ascension and declination, and read the fine hour circle. The divisions of the coarse circles are visible from the floor.
>
> In addition to the ordinary appliances just referred to for actuating the quick and slow motions and clamping the telescope, a complete system of electric motions, clamps and illumination is also provided. Conveniently placed switches at the eye end and on the equatorial head, enable the observer or his assistant on the balcony to start or stop the slow motion motors, and to clamp or unclamp in right ascension and declination by simply pressing knobs. The quick motion motors are controlled from the balcony by switches, and from the eye end by cords. The circles are illuminated by incandescent lamps, connected with switches at the eye end and on the head. Provision is also made for electric illumination of the micrometer wires.
>
> The 40-in. objective of the Yerkes telescope was made by the firm of Alvin Clark & Sons, Cambridgeport, Mass., from disks furnished by Mantos of Paris. The crown lens is about 2½ ins. thick at the center and ¾-in. at the edge; it weighs 200 lbs. The flint lens, which is separated from the crown by a distance of 8⅜ ins., is about 1½ ins. thick at the center, 2 ins. thick at the edge, and weighs over 300 lbs. The lenses are mounted upon aluminum bearings in cast-iron cell.

The structural work for the dome and rising floor was designed by the King Bridge Co., Cleveland, O., Mr. W. P. Brown, Assoc. M. Am. Soc. C. E., Engineer, under the direction of Warner & Swasey, of Cleveland, O., who had the contract for the dome as well as for the telescope. The erection was done by R. S. Write & Co., of Pittsburg, Pa. We are indebted to these various firms and to Prof. Geo. E. Hale, of Yerkes Observatory, for the information from which this description has been prepared.

NOTES FROM RECENT WATER-WORKS REPORTS.

Unusual precautions to secure water tightness were taken in the construction of the larger Wachuset aqueduct of the Metropolitan water system where it is laid on the Assabet bridge. This bridge is of masonry, 359 ft. long, with 30 ft. of masonry aqueduct not on the bridge. The interior lining of the aqueduct is of 8 ins. of brick. A continuous lining of sheet lead was placed back of the brick. The sheets were 16 ft. long, 9 ft. wide, and weighed 5 lbs. per sq. ft. They were burned together without the use of solder. Before placing the lead the bottom and sides of the aqueduct against which it was to be placed were smoothly plastered, and then painted with asphalt. After the lead sheets were in place they were covered with a thick layer of asphalt. The top of the whole bridge was covered with granolithic material laid on two thicknesses of roofing felt, covered with coal tar. This was done to prevent the rain from soaking into the masonry, as well as to give the bridge a suitable finish. Various other features of the work of the board have been described in these columns from time to time. The report of the board for 1897 is a very interesting document. Mr. F. P. Stearns, M. Am. Soc. C. E., of Boston, Mass., is Chief Engineer of the work, and Mr. Thos. F. Richardson is Engineer of the Dam and Aqueduct Department, under which head comes the job described above.

The entire flooded area of the new Hobbs Brook storage and settling reservoir of the water-works of Cambridge, Mass., was cleared of all muck and other soil containing organic matter until sand, gravel or boulders were reached. The basin has an area of 653 acres and a storage capacity of 1,500,000,000 gallons. About 300 acres of land surrounding the water surface was bought by the city for the sanitary protection of the water. A large amount of riprapping of artificial slopes of the basin was done in order to prevent the growth of vegetation and erosion of the banks by waves, each of which might prove deleterious to the stored water. The riprapping, to the close of 1897, had cost about $125,000. The cost of removing the soil, mentioned above, is not stated, but it must have been large. This work is one of the most notable instances of water supply protection that has yet arisen in this or any other country. Practically nothing of the sort has been done outside of New England, and most of this work there has been confined to Massachusetts, and in that state to Boston and its vicinity. Mr. Edwin C. Brooks is Acting Superintendent of the Cambridge water-works.

A wrought-iron water tank, 65 ft. in diameter, 55 ft. high, and having a capacity of 1,365,000 gallons, was built at Fall River, Mass., in 1897. The bottom of the tank is made of ½-in. plates. The side plates are from 11-16 to 5-16-in. thick. Angle irons ½-in. thick are placed at the top and bottom. The bottom angle is 5 × 5 ins., on the outside, double-riveted to the bottom and sides. The top angle is 5 × 5 ins., with the horizontal member down. Although the water consumption at Fall River in 1897 was only 36.29 gallons per inhabitant, or 37.64 per consumer, Mr. Patrick Kieran, Superintendent of the water-works, shows by tables and diagrams that 40% of the pumpage can be accounted for only by leakage from the mains or else by leakage and waste through unmetered services. Of 6,422 services, 5,954 are metered. The water unaccounted for is heaviest in the winter months, indicating that unmetered consumers let the water waste to prevent their pipes from freezing. Mr. Kieran advises that meters be placed in a number of places where the premises are connected with the sewers.

The new Hawkes Brook storage reservoir of the water-works of Lynn, Mass., yielded good water when first drawn from, contrary to the experience with many new reservoirs. This is attributed by Mr. John C. Haskell, Superintendent of the water-works, to the stripping of the site of all organic matter down to "the level at which water can waste from the pond," and covering the remainder of the flooded portion "with about 1 ft. of gravel and sand." The reservoir has an area of 75 acres and a capacity of 300,000,000 gallons. The extra work just described cost about $23,000. In 1894-5-6 much soil was removed from the bottom of Walden pond and the swamps in the drainage area were drained. In 1897 the water from this source was much better than in previous years, when it had had a disagreeable taste and odor.

Two heavy rainfalls occurred at New Bedford, Mass., in 1897, as recorded by Mr. Thos. Rodman, and given in the last report of Mr. R. C. P. Coggeshall, Superintendent of the water-works. On Aug. 16, there was a thunderstorm, during which 3.57 ins. of rain fell in three hours, or 1.19 ins. per hour. Sewers were overtaxed and much damage was done. During a 36-hour storm, beginning on Nov. 1, there fell 5.67 ins. of rain, of which 5 ins. fell in 20 hours. From May 1 to Sept. 1 the total rainfall was 22.69 ins.

Algae growths in the Ludlow reservoir of the water-works of Springfield, Mass., continue to give trouble, as they have to a greater or less extent ever since the reservoir was constructed, now many years ago. The last report of the water commissioners states that by emptying the reservoir five years ago the water from it was greatly improved for two years, but towards the end of the season of 1894, algae again became abundant, while in 1897 the water was rendered unfit for use. The rainfall was so abundant last season that this did not matter much, but the board says the storage will be more necessary in the future, so that "something will soon have to be done to purify this large body of water." The capacity of this reservoir, according to "The Manual of American Water-Works" for 1897, is 2,000,000,000 gallons. Mr. J. C. Hancock is superintendent of these works.

The approximate cost of laying ordinary water pipes at Providence, R. I., with all appurtenances except hydrants, and including iron at $30 per long ton, is given in the last report of Mr. Otis F. Clapp, City Engineer of Providence, as follows:

Size, ins.	Cost, per lin ft.	Size, ins.	Cost, per lin. ft.
4	$0.498	16	$2.403
6	.725	20	3.359
8	.973	24	4.454
10	1.244	30	6.348
12	1.593	36	8.540

Mr. Edmund B. Weston, M. Am. Soc. C. E., is the Assistant Engineer in Charge of the water department.

A special report on "The Relation of the Water Supply, of Elmira, N. Y., to the Typhoid Fever Epidemic of 1896," has recently been published by the Board of Health of that city. The report was made by Prof. Olin H. Landreth, M. Am. Soc. C. E., of Schenectady, N. Y., Consulting Engineer to the New York State Board of Health, and the conclusions drawn were noted in these columns shortly afterward. The water company has since installed a mechanical filtration plant.

The total amount of water pumped at Poughkeepsie, N. Y., was less in 1897 than in 1886, notwithstanding the fact that the number of taps has increased from 1,699 to 2,947 in the last eleven years. This consumption per tap averaged only 572 gallons a day in 1897, against 1,003 gallons in 1886. These figures are doubtless to be accounted for by the fact that of the 1,699 taps in use in 1886, only 433, or less than one-fourth, were metered, while in 1897 over three-fourths of the taps, or 2,244 out of 2,947, were metered. It should also be noted that the water supply of Poughkeepsie has been filtered through these and previous years, and that the filters have long been operated at least to their full capacity. Had the total consumption been allowed to increase as in many other cities, the duplication of the filter plant, recently effected, would have been imperative long ago. The population of Poughkeepsie in 1890 was 22,000, and the average daily consumption in 1897 was 1,688,298 gallons. Mr. Chas. E. Fowler is, and has been for many years, superintendent of the water-works at Poughkeepsie.

Only some 20 to 30 of the 4,187 service pipes connected with the water-works of Yonkers, N. Y., were unmetered at the close of 1897. The estimated population of the city was 42,000, of which it is estimated that 35,000 were on streets provided with water and 34,000 were actually supplied. The average daily consumption, stated in a variety of ways, was as follows: Total, 3,588,307 gallons; per inhabitant, 83; per consumer, 102; per tap, 857; per domestic meter, 174; per manufacturing meter, 7,396 gallons. About 20% of the total consumption passed through the 4,031 domestic meters. Mr. A. W. Kingsbury is now acting clerk of the works, Mr. Jos. Lockwood, for many years superintendent, and lately clerk in addition, having died last August.

The benefits of the meter system are still further illustrated by the last report of Mr. W. C. Hawley, Assoc. M. Am. Soc. C. E., Superintendent at Atlantic City, N. J. The cost of coal used at the pumping stations has been greatly reduced through the reduction in consumption; and enlargements to the plant estimated to cost $250,000 have been indefinitely postponed. Tin-lined galvanized iron has been used with satisfaction for service pipes. Mr. Hawley states that it costs less than the tin-lined lead pipe, and is believed to be as durable. The commissioners of these works state that a reduction in the meter rate from 18 and 14 to 12 cts. per 1,000 gallons has been made possible by raising $12,100 by general taxation, thus placing the burden of fire protection and water used for other public purposes where it belongs, upon the property benefited. The commissioners recommend that the minimum meter rate vary with the amount that would be charged for water at fixture rates.

A special report on filtration has been published by the water commissioners of Reading. Slow sand filtration is recommended, as previously noted in this journal. The pamphlet contains reports by Mr. Emil Nuebling, Superintendent and Engineer of the works, and Mr. Allen Hazen, Assoc. M. Am. Soc. C. E., Consulting Engineer, 220 Broadway, New York city, and copies of reports for the city of Philadelphia, by Prof. E. G. Smith, Madison, Wis., Prof. Wm. P. Mason, Troy, N. Y., and Mr. Rudolph Hering, M. Am. Soc. C. E., New York city. During the investigation preceding the reports, experimental filters were operated for a number of months, including ordinary filter beds and beds built on the plan of the Pennsylvania Sanitation Co., of Philadelphia. Numerous analyses of applied water and effluent are given in the report.

The Great Falls dam across the Potomac River, at Washington, D. C., was raised 2½ ft. in height for a distance of 2,095 ft. in the years 1895 and 1896. As a strong current of water, giving a head of from 3 to 5 ft. on the upstream side, flows over the dam, and as the river carries much driftwood at times, it was decided to use cofferdams, enclosing as much of the dam as the workmen could raise in a single day. Two wooden bulkheads, each 30 ft. long, were placed at the upper face of the dam, inclining upstream and held in place by the pressure of water above, resisted by 1½-in. iron bolts sunk into the old masonry. The bulkheads were composed of five 2 × 12-in. Georgia pine planks, placed edge to edge, fastened together longitudinally by five 2 × 12-in. cleats, 40d. nails being used.

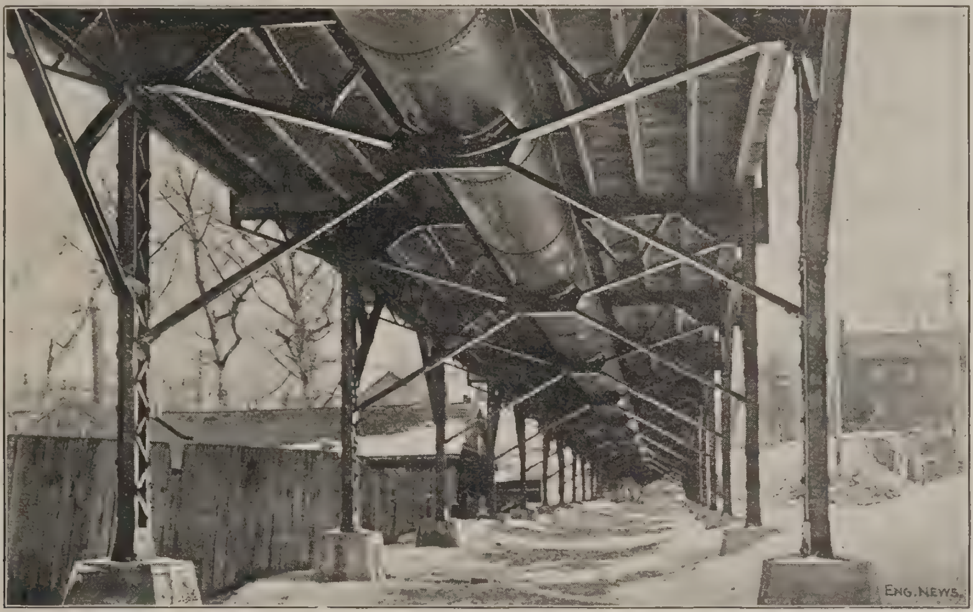
Sand bags were used for end dams. The average width of the masonry was about 8 ft. The work was done by contract in 176 working days, 84 working days being lost by high water, and 23 by lack of stone. The total cost of the cofferdams, including furnishing, setting and calking, was $2,064, or 98½ cts. per lin. ft. The total cost of raising the dam 2½ ft. for a distance of 2,095 ft. was $86,373, including $10,245 for a suspension cableway furnished by Mr. R. H. Hood, of Washington, D. C. The work was carried out under the direction of Capt. D. D. Gaillard, Corps of Engineers, U. S. A., in Charge of the Washington Aqueduct, and is described, with illustrations, in Appendix AAA. of the Annual Report of the Chief of Engineers for 1897.

The above report, which doubtless may be obtained by addressing Captain Gaillard, contains an interesting account of measurements of the flow through the old Washington Aqueduct. In this work the velocity was obtained by using a Buff & Berger current meter, provided with an electric register. Readings were taken through manholes, an index frame marked to correspond to 33 different points in the cross-section of the aqueduct being employed in taking the readings. The readings recorded were the average of two readings at each point, the second set in inverse order. The cross-section of the aqueduct was divided into 16 areas, "and the volume of flow per second through each of these areas was computed. The mean velocity was then computed by dividing the sum of these volumes by the total area of the conduit section." The carrying capacity of the conduit at low water in the Potomac was found to be about 75,000,000 gallons per day. The report contains a discussion of some of the hydraulic problems involved which might be of interest to those having large aqueducts in their charge, although the local conditions at Washington are in some respects exceptional.

Crude oil was used for fuel by the Detroit water-works for several years, but was discontinued in 1896, after the price had been raised from 1.55 to 2.8 cts. per gallon. For the year 1895, with crude oil at 1.55 cts. per gallon, the cost of fuel was $2.18 per 1,000,000 gallons. In 1897, using semi-bituminous coal costing from $2.40 to $2.60 a ton, the cost of fuel was $1.40 per 1,000,000 gallons, and the pressure had been increased 4½% meanwhile. The Detroit works continue to show the beneficial results of waste prevention, the total pumpage for 1897 being less than it was in 1887, although the number of families supplied has increased from 34,486 to 54,945. There seems to be plenty of room for further improvement, as the daily consumption in 1897 is given as 125 gallons per capita. The already low water rates were cut in half during 1897, and it estimated that the average amount paid by each family for water in 1898 will be only $4.02. Mr. L. N. Case is general superintendent of the works, and Mr. Gardner S. Williams is civil engineer. During the year Mr. Williams has made studies, by means of temperature observations and otherwise, of the possible pollution of the supply at the intakes from shore currents. The temperature studies were based on the fact that the shore currents would be warmer than the others.

The report of Mr. F. E. Herdman, Chairman of the Water Committee of Winnetka, Ill., is a good example of the value of an engineer as a member of a water board. Winnetka is a small suburb of Chicago, which built works in 1893. In his report Mr. Herdman presents a careful analytical study of the financial operations of the works, and shows how economies might be introduced by improvements in the plant. His report is a strong contrast with those of most small and many large works, and shows the value of accurate scientific records. Comparatively few works, if we can judge from the annual reports received, have their records kept in a way designed to throw the proper light on the economy of the operation of the different parts of the plant. Judging from the experience at Detroit, cited above, Mr. Herdman's allowance of 1.7 cts. per gallon as the price at which crude oil could be bought as fuel is too low, unless freight rates and other conditions would be more favorable in the vicinity of Chicago than at Detroit. The latter city paid only 1.5 cts. per gallon for oil at the start, but the price was advanced slightly soon afterwards, and finally, by a sudden raise, was fixed at 2.18 cts.

The last report of Mr. F. W. Cappelen, City Engineer of Minneapolis, contains descriptions of improvements to the water-works system, including a double line of 50-in. steel force and distributing mains 16,676 ft. long, 890 ft. of single 50-in. steel pipe, and 15,758 ft. of single 16-in. cast-iron drain pipe, apparently in the same trench as the steel pipe. The pipe line included a submerged river crossing about 750 ft. in length. The contract for this work, with all appurtenances, was let to the T. A. Gillespie Co., of Pittsburg, Pa., for $343,726. Winston Bros., of Minneapolis, bid $477,500 for the job, using cast-iron throughout.



VIEW UNDERNEATH APPROACH TO THAMES RIVER BRIDGE, LONDON, ONT., SHOWING STEEL PIPE SEWER.

A. O. Graydon, City Engineer; Willis Chipman, Consulting Engineer; E. Leonard & Sons, London, and Central Bridge & Engineering Co., Peterboro, Contractors.

The coating for the steel pipe was mineral rubber asphalt from Utah, manufactured by the Assyrian Asphalt Co., of Chicago, the pipe being dipped vertically in a bath at a temperature of 300° F. This coating, or some other equally good, was named in the specifications, the final determination to be made by the city engineer. Mr. Cappelen tested this coating, together with Trinidad asphalt, mixed with dead oil, used by the Hugo Iron Works, of Duluth, Minn., on the new 42-in. steel pipe in that city; California asphalt from Waldorf, Cal., and the same mixed with about 40% of maltha; and finally a coating from Dennis, Long & Co., of Louisville, Ky. The details of these tests and analyses of the mineral rubber, Trinidad and combined California asphalt and maltha coatings, which three were considered the best of the five, are given in the report. Regarding the mineral rubber coating, Mr. Cappelen says:

> Coating covered the pipe splendidly in all cases and somewhat thicker for the 300° (against 400°) temperature and stood hammer test perfectly. The material is so elastic that by cutting into the coating and entirely removing some of it, the opening can be covered by simply hammering the edges around the space so that it is impossible to see the joint. The coating did not foam even up to 700° F.
>
> The mineral rubber coating (on special plates.—Ed.) was not affected by muriatic acid (H C L) nitric acid ($H N O_3$) nor by sulphuric acid $H_2 S O_4$.

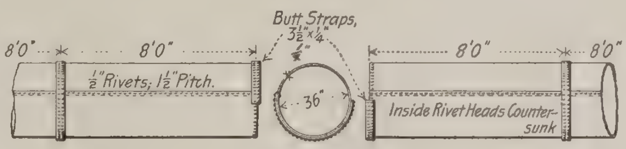
The cost per ton of the mineral rubber coating is given as about $60; for the Trinidad, $45; and for the California and maltha, $40. The contract for this pipe line was executed on June 22, the award having been made on June 18, and the contract time for doing the work being five months, with a bonus and penalty clause of $250 per day. Ground was broken July 18, the first pipe was laid July 29, and the work completed Nov. 9, the contractors thus earning a bonus of $2,250. A force of 500 men, two steam shovels, for trenching and back-filling, respectively, two air compressors and one pumping outfit were employed. On Aug. 24 there were laid 1,120 ft. of 50-in. steel pipe, which Mr. Cappelen says "is a record unequalled anywhere."

The report contains a "Chart Showing Relations Between Rainfall, Sanitary Improvements and Typhoid Fever in Minneapolis, Minn., from 1870 to 1897." The chart shows that while sanitary improvements have lowered the typhoid death rate very materially, there is still opportunity for much further improvement, there having been 70 deaths per 100,000 from typhoid in 1897. Filtration of the whole water supply is a part of the scheme of improvements adopted some time ago.

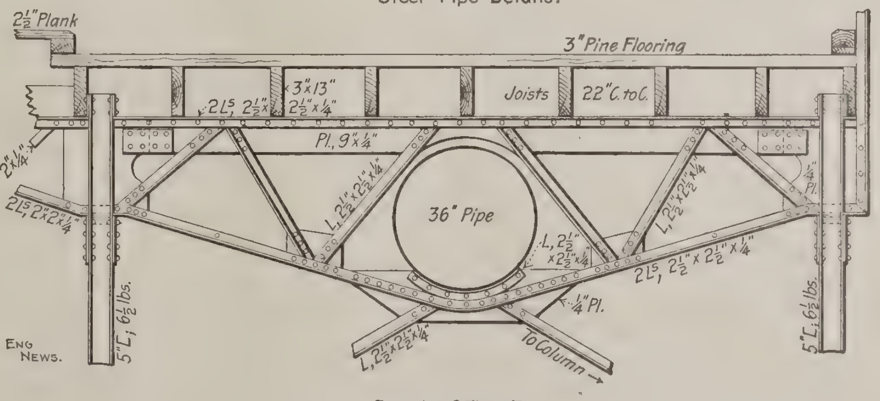
To encourage the use of meters at St. Paul, they are furnished by the water department without charge to the consumer, and also set free of charge. We have already expressed our opinion on this subject to the effect that meters should be considered as a part of the water-works plant and charged to construction. Of course there may be exceptions to this, as well as any other detail of water-works practice. In some cases the financial condition of the works, or the powers granted to the water department, will not allow the practice, but generally these difficulties might be surmounted if the resulting advantages were half appreciated. Mr. John Caulfield is secretary of the St. Paul works.

CARRYING A STEEL PIPE SEWER ACROSS A BRIDGE AT LONDON, ONTARIO.

In the construction of the intercepting sewers for London, Ontario, it was necessary to carry a 36-in. main sewer across the River Thames at an elevation of 24 ft. above low water. The portion of the sewer exposed is about 630 ft. long, and it was thought advisable to construct a steel truss bridge, of 162 ft. span, with viaduct approaches of 468 ft. to carry a 16-ft. roadway and 4-ft. walk, and supporting beneath the floor a 36-in. steel pipe for the sewage flow. The floor beams throughout were spaced 18 ft. apart, and their construction is clearly shown on the cut herewith.



Steel Pipe Details.



Details of Floor Beam.

CROSS-SECTION OF THAMES RIVER BRIDGE, SHOWING METHOD OF SUPPORTING STEEL PIPE.

The sewer pipe was built of ¼-in. plates, 8 ft. long, lap-jointed longitudinally and butt-jointed transversely. Below the horizontal diameter all rivet holes were countersunk, thus leaving the bottom half perfectly free from obstructions. The pipes were given two coats of pure graphite paint (inside and outside), over one coat of red lead. They were put together in the shop in 32-ft. lengths, and, to facilitate jointing in the field, the butt-strips on their ends were made in halves (upper and lower alternately). No difficulty was found in putting them in position, as much as 200 ft. being erected in one day under the viaduct. There are three curves in the pipe line and these were made to conform to a central radius of 74 ft.—the center of each seam coming on the arc of the circle.

The piers and pedestals (for columns) were made of concrete throughout, with four stone bridge-seats. The main body of the work was composed of concrete of the following proportions: Six parts of crushed stone, two parts sand, one part crusher screenings, one part Portland cement. The whole of the exposed surfaces were faced with 3 ins. of 2 to 1 mortar deposited at the same time as the rest of the work, and pressed firmly against the molds.

The concrete was laid in layers of from 9 to 12 ins. and gently rammed, not more than 3 ft. in depth being laid in any one day. On removing the molds the main piers were washed over with three coats of cement wash. The tops of the piers and pedestals are finished with 6 ins. of a concrete made of one part of cement, one part of sand and three parts of crusher screenings. A stonemason having to cut out some of this concrete a month later, said "it was harder cutting than limestone."

The molds used were of smooth 2-in. planks made in 4-ft. frames, held in position by iron rods passing through the piers, and so arranged that small bolts with hooks at their ends could be easily drawn out when the molds were to be removed. The west river pier was laid on a 10-in. timber foundation, resting on piles spaced 2 ft. 6 ins. on centers, while for the east pier hard clay was found at about 6 ft. below the river level. About 425 cu. yds. of concrete were laid. Canadian Portland cement was used throughout, giving high tensile tests and being very finely ground. Not more than 5% residue was left on a 2 sieve of 100 meshes per inch.

The work was designed and carried on under the direction of Mr. A. O. Graydon, City Engineer, and Mr. Willis Chipman was Consulting Engineer for the sewer system. The steel pipe was built by E. Leonard & Sons, of London, and the Central Bridge & Engineering Co., of Peterboro, built the bridge and erected the pipe. The cost of the work was about $12,750. We are indebted to Mr. W. T. Ashbridge, Assistant Engineer, in charge of sewers, for the material from which our illustrations and description are prepared.

TRACK ELEVATION AND DEPRESSION AT THE 16TH ST. CROSSING, CHICAGO.

One of the most extensive and complicated systems of railway tracks in the world is that which occupies the district along the Chicago River, from 14th St. to 22d St., which district contains the freight and terminal yards of a number of railways, and through which run a multitude of main tracks, crossing and connecting in a most bewildering manner. In fact, if a person undertakes to walk across this district he finds it somewhat difficult to keep his bearings. On the large proportion of this district, which is devoted exclusively to railway purposes, there is little need of track elevation, and safety to the train service entering and leaving the district is ensured by a complete interlocking switch and signal plant established at the outlet at Stewart Ave. and 21st St. This plant was described and illustrated in our issues of Sept. 22, 1892, and Nov. 16, 1893, and in the latter issue we published a map of the tracks throughout this entire district.

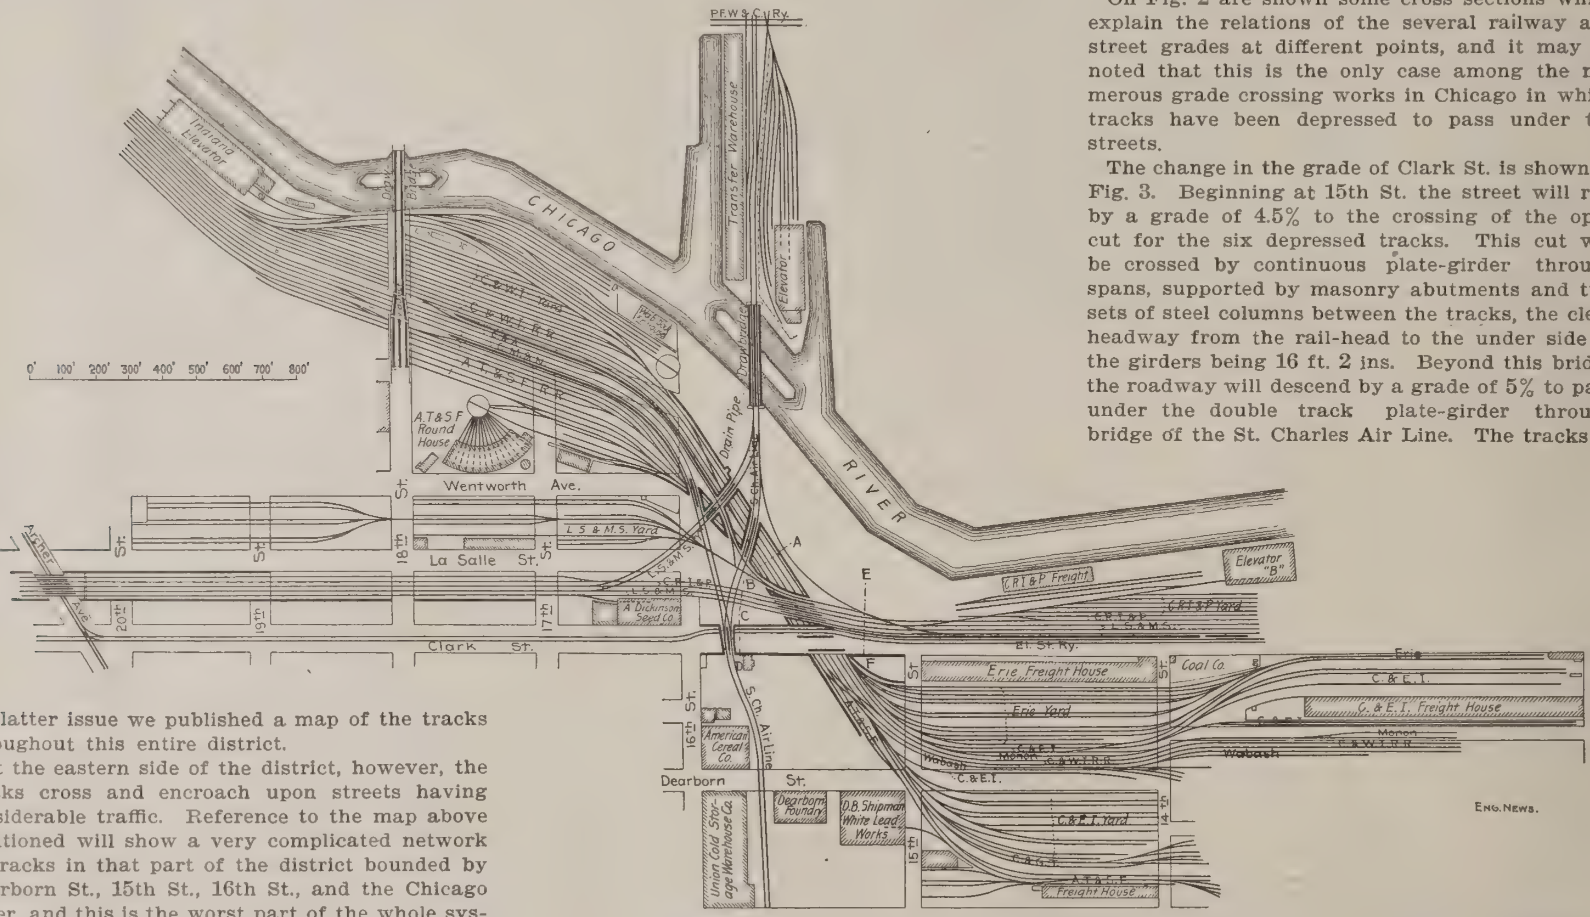


FIG. 1.—PLAN OF TRACK ELEVATION AND DEPRESSION TO ELIMINATE THE GRADE CROSSINGS AT 15TH AND 16TH STS., CHICAGO.

James Dun, M. Am. Soc. C. E., Supervising Engineer;
G. W. Vaughn, M. Am. Soc. C. E., Engineer in Charge.

At the eastern side of the district, however, the tracks cross and encroach upon streets having considerable traffic. Reference to the map above mentioned will show a very complicated network of tracks in that part of the district bounded by Dearborn St., 15th St., 16th St., and the Chicago River, and this is the worst part of the whole system, as there is a constant traffic of trains and switching movements, interfering with and endangering the street traffic. It is this section of the district which is dealt with in the present article. The interlocking plant above mentioned does not protect any tracks or crossings north or east of 18th St., and the railway crossings of this section were protected only by flagmen, while the Clark St. crossing was protected by gates.

This particular section, known as the 16th St. crossing, is probably the most complicated system of grade crossings in Chicago. It comprises a network of connecting and intersecting tracks, over which there is a continual traffic, including main line and suburban passenger trains, freight trains, light engines, and freight and passenger switching movements, to say nothing of the constant service of electric cars on Clark St. There is a daily movement of 5,000 cars and 500 engines, and the passage of this crossing was often enough to try the nerves of the street car passengers, who beheld engines and trains apparently moving upon them from all directions.

At this point the parallel tracks of the Chicago, Rock Island & Pacific Ry. and the Lake Shore & Michigan Southern Ry., running south from the Van Buren St. terminal station, and close to the west side of Clark St., are crossed diagonally by the tracks of the Atchison, Topeka & Santa Fe Ry. and the Chicago & Western Indiana R. R., which start from the Polk St. passenger terminal station and the various freight yards east of Clark St. Just beyond, the roads first mentioned are crossed at right angles by the tracks of the Chicago, Madison & Northern Ry. and the St. Charles Air Line (Illinois Central R. R.), which connect with the Illinois Central R. R. main line tracks on the lake front. These are not merely crossings, but every line is connected with every other line and with numerous freight tracks in order to provide for the interchange of cars between the various roads. Some idea of the traffic may be gathered when it is explained that, in addition to the roads named, the trains of the New York, Chicago & St. Louis Ry. now run into the Van Buren St. terminal station, and that the Chicago & Western Indiana R. R. is a terminal road used by no less than seven railways (the Atchison, Topeka & Santa Fe Ry., Chicago & Eastern Illinois R. R., Grand Trunk Ry., Chicago, Indianapolis & Louisville Ry., Erie R. R. and Wabash R. R.).

When the city of Chicago undertook in earnest the elimination of the numerous grade crossings of the streets by compelling the railways to elevate their tracks, this crossing came up for consideration, but the difficulties of preparing a satisfactory plan which would be accepted by the city and by all the railways interested were so great that the matter has been laid aside from time to time until the present year, when, by agreement, the entire work was put into the hands of Mr. James Dun, M. Am. Soc. C. E., Chief Engineer of the Atchison, Topeka & Santa Fe Ry. The difficulties arose largely from the fact that it was desired, in making the change, to separate the grades of the different railways, and thus, as far as possible, eliminate track crossings as well as highway crossings at grade. Considering that the tracks had still to be connected by switches and turnouts, it will be seen that the problem to be solved was difficult and complicated. The plans were finally agreed upon, however, by all parties concerned. Work was commenced on April 24, and is to be completed this season. Major G. W. Vaughn, M. Am. Soc. C. E., is the Engineer in Charge.

The accompanying plan, Fig. 1, shows the arrangement of tracks as it will be when the work is completed. The four tracks of the C., R. I. & P. Ry. and the L. S. & M. S. Ry. (running north and south), will be elevated about 12 ft., as a continuation of their track elevation which now extends north from Englewood to 16th St. (Eng. News, March 17.) The six diagonal tracks (two for the A., T. & S. F. Ry. and four for the C. & W. I. R. R., and the lines using it), will be depressed about 9 ft., passing under the elevated lines and under Clark St. in an open cut with vertical concrete retaining walls. The St. Charles Air Line and C., M. & N. Ry. will be elevated, so that there will still be one railway crossing at grade, a double track line crossing four tracks at right angles. The arrangement makes it necessary to change the grade of Clark St., which will be raised to pass over the depressed tracks and then inclined downward to pass under the elevated tracks of the St. Charles Air Line. The elevation of this latter line has made it necessary to raise the grade of the South Side Elevated R. R., which crosses it just east of State St.

On Fig. 2 are shown some cross sections which explain the relations of the several railway and street grades at different points, and it may be noted that this is the only case among the numerous grade crossing works in Chicago in which tracks have been depressed to pass under the streets.

The change in the grade of Clark St. is shown in Fig. 3. Beginning at 15th St. the street will rise by a grade of 4.5% to the crossing of the open cut for the six depressed tracks. This cut will be crossed by continuous plate-girder through spans, supported by masonry abutments and two sets of steel columns between the tracks, the clear headway from the rail-head to the under side of the girders being 16 ft. 2 ins. Beyond this bridge the roadway will descend by a grade of 5% to pass under the double track plate-girder through bridge of the St. Charles Air Line. The tracks of the Clark St. electric line, however, will descend on a somewhat steeper grade. These tracks will be at one side of the street, as shown in Figs. 1 and 2, and the portion of the roadway which they occupy, 26 ft. in width, will be separated from that used for street traffic, 42 ft. wide, by a dwarf wall and iron fence. Under the Air Line railway bridge the clear headway will be 12 ft. for the roadway and 13 ft. 6 ins. for the electric railway. South of this bridge the grades of the roadway and the car tracks will rise, approaching each other until they coincide at the point where they meet the present grade of the street, just north of 16th St. The new grade of the street will be about 10 ft. above the present grade at the depressed tracks, and about 1.6 ft. below it at the bridge under the St. Charles Air Line.

The retaining walls are all of concrete, and present a very good appearance, while the great advantage of this material is its low cost and the rapidity with which the walls can be built. The foundations are in a good stiff clay, the engineers having been agreeably disappointed in not finding the soft spots or pockets which had been expected. The concrete is mixed by machinery in a work train consisting of cars loaded with cement, sand and broken stone, a flat car at the head of the train being equipped with an engine and boiler to drive the mechanical mixer. When the train is in place on the side track, planks are nailed upon the cars, along which the materials are carried in wheelbarrows to the mixing plant. The concrete is made very wet, is carried to the site in iron wheelbarrows, and is kept well rammed. Two of these mixing plants are in use, being operated by the Brownell Improvement Co., which has the contract for the concrete work, which work is to be finished by August.

The incidental work includes the laying of new gas mains across the site, and the laying of pipes to drain the open cut for the depressed tracks. For this latter purpose 12-in. pipes will lead to three 24-in. pipes discharging into the river. To prevent flooding by high water in the river, there will be a pump house, with stop wall and gates built just behind the retaining wall. The gates will be closed by the back pressure from high water in the river, and a centrifugal pump will then lift the drainage water from a well or sump and discharge it into the river. During construction there is a continual rearrangement of the tracks. There are still in use 35 grade crossings within a radius of 150 ft., and the handling of trains over these various crossings is effected by a system of watchmen and flagmen who are very expert in keeping the traffic moving without confusion or accident. During the work a part of Clark St. has been closed to traffic and the electric cars have been diverted to another route.

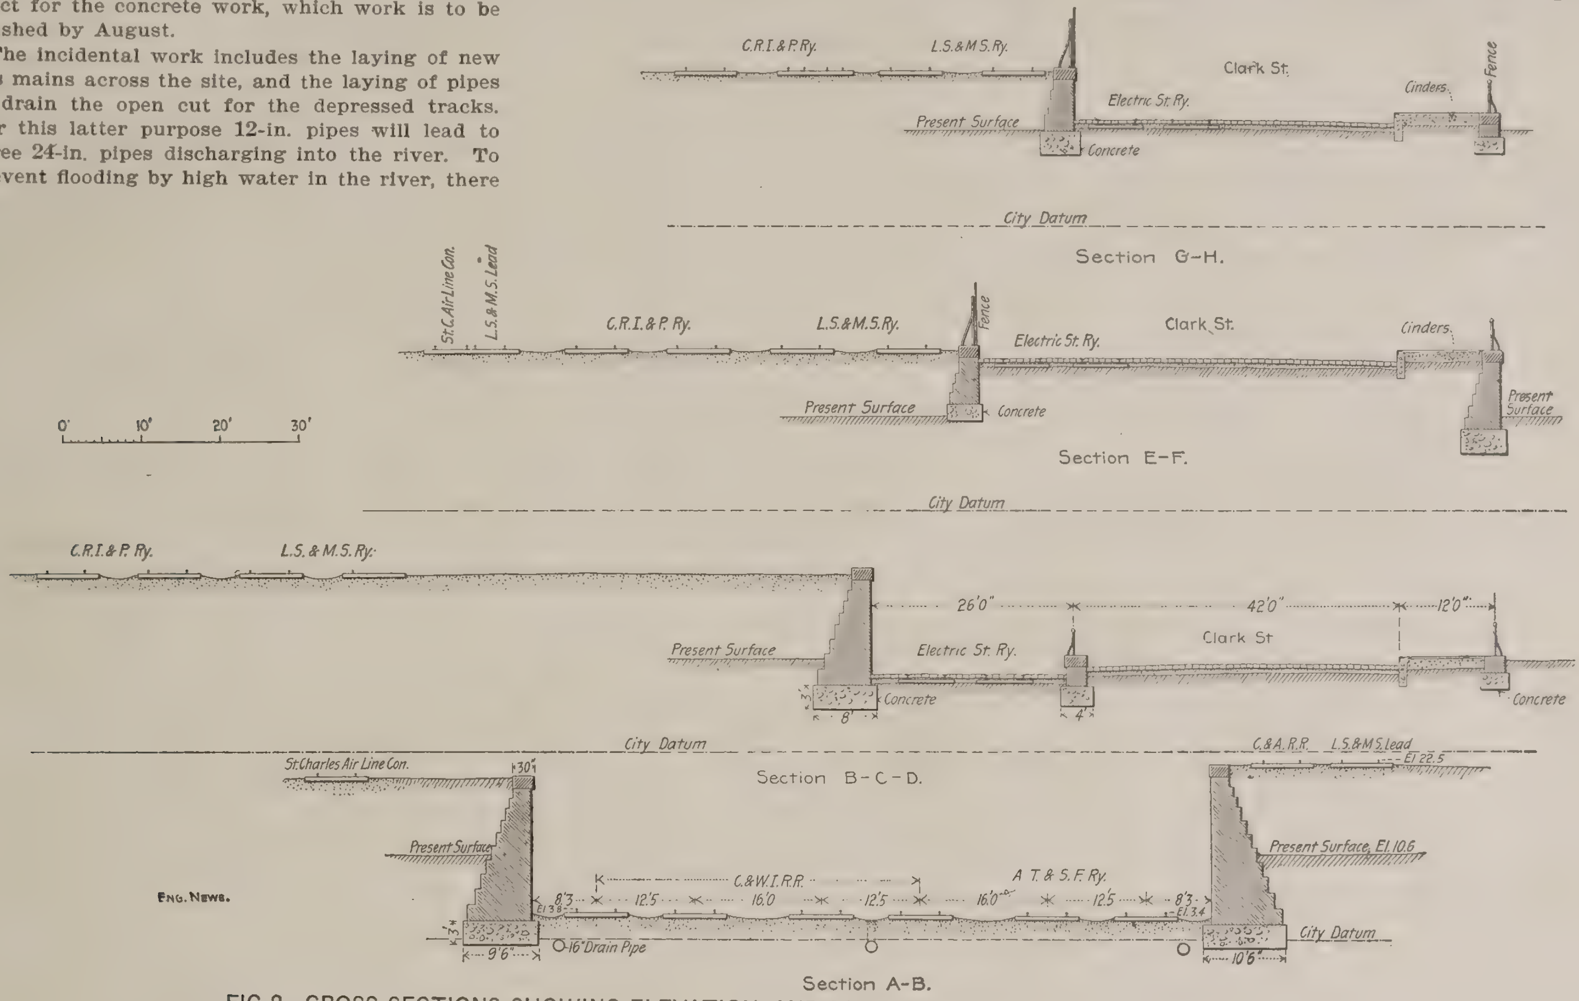

FIG. 2.—CROSS SECTIONS SHOWING ELEVATION AND DEPRESSION OF RAILWAY AND STREET GRADES.

When the retaining walls are built as far as the existing arrangements will permit, the filling in will be done for the elevation of the tracks of the L. S. & M. S. Ry. and C., R. I. & P. Ry. to their permanent grade. At the same time, some of the tracks of the A., T. & S. F. Ry. and C. & W. I. R. R. (which are ultimately to be depressed) will be raised to the same grade by sand filling, and will temporarily cross the other elevated tracks at grade. When this is done, the other tracks of the two latter roads, remaining on the surface, will be lowered to their permanent grade, and as soon as these are ready for traffic the temporarily elevated lines will also be depressed. The plan of gradually elevating the tracks by filling in with sand has been adopted as the one enabling the work to be carried out with the least interference to the heavy traffic. There is no specially important work of a structural character, but the most interesting feature is the execution of the work of making such radical changes in the grades of this complicated system of tracks, with all their switches and frogs, without stopping or interfering with the traffic.

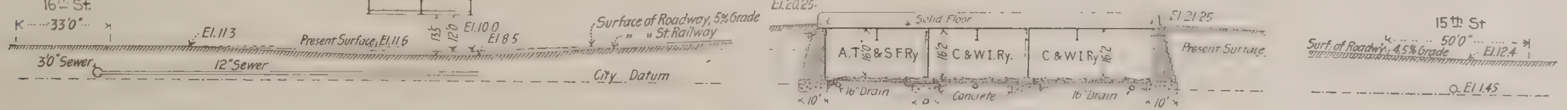

FIG. 3.—PROFILE OF NEW GRADE OF CLARK ST.

It is estimated that the work will cost about $400,000, but the apportionment of cost between the several railway companies interested can only be determined after the work is done, as previous to that time the monthly apportionments will vary as the work done for the benefit of each during the month varies.

* * *

THE NEWFOUNDLAND RAILWAY CONTRACT, entered into on March 15, 1898, between the Governor of Newfoundland and Mr. Robert G. Reid, of Montreal, is briefly presented, as follows, by Mr. M. J. Carter, U. S. Consul at St. Johns: In 1893 Mr. Reid contracted to build certain railways in this island for the government and received in land subsidies 2,500 acres per mile of road. By the present contract Mr. Reid controls the whole 775 miles of railway in Newfoundland for 50 years, and is to maintain and operate them under fixed maximum rates for transport of passengers and goods, and a subsidy of $42,000 per annum for mail service. In consideration of these obligations the government grants him in fee simple, in addition to the subsidies received in 1893, 5,000 acres of land for each mile of main line or branch throughout the entire system operated. These lands will be laid off in blocks one mile in length and ten miles deep, on either side of the line; the contractor and the government alternately selecting the blocks. Mr. Reid agrees to renew the rails on certain lines to the extent of $100,000, and to build a new branch from Topsail to St. Johns for $15.600 per mile paid by the government. For improved mail steamer service the government grants special subsidies; it transfers to the contractor the St. Johns dry-dock, for $325,000, and gives him control and management of the government telegraph lines, until April 15, 1904, on payment of $10,000 per year, and after that, to the end of the 50-year lease, the contractor must maintain these lines free of cost to the colony. The contractor agrees to have an electric railway built in St. Johns, while the government is to pave certain streets at a cost not exceeding $140,000. All disputes are to be referred to two arbitrators appointed by the two principals, and a third named by the Supreme Court. In consideration of the new contract Mr. Reid agrees to reassign and transfer to the government, at the end of 50 years, 2,500 acres of land for each mile of railway, to be deducted out of the land subsidies. The properties transferred to Mr. Reid, exclusive of land, cost the Newfoundland government as follows: Railways, $12,000,000; St. Johns dry-dock, $600,000; telegraph lines, $130,000; total, $12,730,000. For this Mr. Reid pays $1,000,000, out of which subsidies are to be returned for improvements. The government losses in operating these properties, per annum, were estimated as follows: On railway, $300,000; on telegraph lines, $18,000; on St. Johns dry-dock, $20,000; a total of $338,000 per year.

PRIZE DESIGNS FOR ARTISAN HOMES are requested by the Executive Committee of the Twentieth Triennial Exhibition of the Massachusetts Charitable Mechanics' Association. The prize offered for the best design is $750, taken from a fund provided by Dr. Geo. C. Shattuck. The nature of the work required is described as follows:

Upon a city block, 200 × 800 ft., surrounded on the four sides by streets, it is required to develop a scheme for housing, under the requirements of the Boston Building Laws, in the most convenient, sanitary and economical way, in other than a single structure, such number of artisan households as will promise a fair income on the investment. The land is to be reckoned as costing $1.50 per ft., and the rentals paid are to be considered as follows: Single room, $1.00 per week; two rooms, $1.50 per week; three rooms, $2.00 per week, and four rooms, $2.50 per week. It must be borne in mind that suites of four rooms are more in demand than smaller suites, and that single rooms are in comparatively little demand.

Full particulars regarding the number, size and scale of the drawings and other information concerning the competition can be had by addressing the Association at Mechanics' Building, Huntingdon Ave., Boston, Mass.

SUBSCRIPTION RATES: United States, Canada and Mexico, One Year, $5.00; *6 months,* $2.50; *2 months,* $1.00. *To all other countries in the Postal Union: Regular Edition, One Year,* $7.60 (31 *shillings*); *Thin Paper Edition, One Year,* $6.31 (26 *shillings*). *SINGLE COPIES of any number in current year,* 15 *cents.*

Mailing addresses may be changed at will by sending both old and new address. The number on the address label of each paper indicates when subscription expires, the last figure indicating the year and the one or two preceding figures the week of that year; for instance, the number 328 *means that subscription is paid to the 32d week (that is the issue of Aug.* 11) *of the year* 1898; *the change of these figures is the only receipt sent, unless by special request.*

ADVERTISING RATES: 20 *cents per line. Want notices, special rates, see page* 18. *Rates for standing advertisements sent on request. Changes in standing advertisements must be received by Monday afternoon; new advertisements, Tuesday afternoon; transient advertisements by Wednesday noon.*

The report of the board of officers appointed to examine the wrecks of the four Spanish armored cruisers, sunk off Santiago, makes interesting reading to naval experts throughout the world. There has never been so good an opportunity to test the efficiency of modern warships and their armament in actual combat, and as a result some remodeling will be necessary in the design of future ships of this class. One of the most important lessons taught is that torpedo tubes on battleships and cruisers, at least when located above the water-line, not only introduce an unnecessary complication into the armament, but form a great and positive danger to the ship itself. The report shows that the Spanish cruiser "Vizcaya" was practically destroyed by one of her own torpedoes; and while it is not stated whether the explosion was brought about by the direct impact of a projectile, or by the fire resulting from the explosion of the shells from the attacking fleet, the fact remains that several hundred pounds of gun-cotton did explode on this ship and wrought greater havoc than the hail of projectiles to which she was subjected.

The enormous value of rapid-fire batteries is attested in this battle where four ships protected by 12-in. armor belts were destroyed. It appears that only one 12-in. projectile struck any of these vessels, and yet they were destroyed in a comparatively short time. The terrific and accurate fire of our sailors drove the Spaniards from their guns, killed many men, pierced the parts unprotected by the heaviest armor, and set fire to one after another of the Spanish ships. The fact that fire played such an important part in the destruction of at least two of the Spanish ships fully justifies the efforts of our naval authorities in reducing the amount of woodwork on battleships to a minimum, and leaving it out entirely wherever possible. Early in the Santiago fight the water pipes on the "Infanta Maria Teresa" were broken, and when a bursting 6-in. shell set her on fire there was no way of putting it out.

As a result of the Santiago fight it is very evident that rapid and accurate gun-fire, combined with speed in the vessels and good seamanship, will virtually decide the battle of the future before the heavy ships can approach each other near enough to use a torpedo on the enemy's hull. Hence, torpedoes on this type of vessel are useless as a means of attack, and dangerous when exposed to the long-range fire of an enemy. The accuracy of the Yankee gunners is shown by the fact that the "Almirante Oquendo" was struck 66 times in the parts of the ship not now submerged; the "Infanta Maria Teresa" contains 33 shot-holes, the "Vizcaya" 24, and the "Cristobal Colon," which was purposely shielded by the others, was struck 8 times in the hull. The torpedo boat destroyers were so completely wrecked by our projectiles that they are beyond all hope of raising. We can honor the reckless valor of the Spanish admiral and his men, and regret the destruction of so much valuable property; but the experience is extremely useful in the design of our future naval armaments, and the United States, as in 1862, has the opportunity to teach European nations a few things relating to ships and guns that they did not know before.

◆

The American wire rod industry has had a remarkable history. Previous to 1882 nearly all the rods made in the United States were imported, the importations reaching nearly 200,000 tons in one year. In 1882 a rod mill was built at the Cleveland (O.) Rolling Mill by Mr. William Garrett, which was far in advance of any other mill in its capacity for turning out product at a minimum cost for labor. Soon Mr. Garrett was building new mills at other steel works, each one an improvement on the one preceding. In 1897 the United States produced nearly 1,000,000 tons of rods, 80% of them in mills of the Garrett type, and American rods are exported to every quarter of the globe. The sequel to this story is now told by the "Iron Trade Review," which says that Mr. Garrett has been occupied abroad for the past six months in equipping foreign manufacturers with American machinery which will enable them to meet American competition. An improved Garrett mill has been erected at Havre, France, and one of the largest wire rod manufacturers in Germany is about to duplicate the twin mill at Joliet, Ill., with the exception that it will begin rolling with a 5-in. instead of with a 4-in. billet. It is apparent from this that the French and German manufacturers are getting ready to put a stop to the exports of wire rods from the United States into European markets.

◆

The far-reaching importance of the application of electric traction to street and suburban railways, which has been made in the past decade, is well pointed out in a recent article in the St. Louis "Globe-Democrat." The writer makes the reasonable assumption that the average city worker cannot afford to spend more than an hour in transit between his home and his business, and this unit of time practically limits the availability of suburban districts as economic places of residence. With the old horse-car a speed of 6 miles an hour was the best attainable, and from any one center this gave a diameter of 12 miles and an area of about 110 square miles for the district within an hour of the central business section. Electric traction, however, increases the rate of speed to 10 miles per hour, and the area within an hour of a given center to over 300 square miles, or nearly three times the area accessible in this time by the horse-car. The electric car has thus much the same influence on the growth of cities that the horse-car originally had when it did away with the old-time necessity of living within walking distance of one's place of work. The benefit to the workingman in both cases was the possible removal of his home from crowded and unsanitary centers to a location in more remote, cheaper and healthier districts. While in Europe street railway rates are regulated by the distance traveled, as on steam railways, the American system of uniform fare provides for a short ride at a comparatively high rate, and very cheap long distance travel. Thus, the extension of the one hour radius by the application of electricity does not, as a rule, increase the rate of fare.

◆

There is no doubt as to the widespread benefits resulting from the use of electricity on suburban lines; both to the workingman, in providing cheaper and better houses, and to the community at large by increasing property values in converting agricultural land into building sites. But our contemporary omits consideration of one important element in comparing the speed of the electric car and the horse-car and the areas affected. In our issue of June 11, 1896, Dr. Louis Bell presented a study of the City of Boston and its suburbs, showing the areas within 15 and 30 minute distance of the business district by both horse and electric cars. Dr. Bell showed that in crowded business centers the average speed of both vehicles is almost the same for the first 15 minutes at least, the common rate being about 6 miles per hour. But for the second 15 minutes the electric cars gain over the horse-cars, in proportion as the streets become less crowded with business traffic; and, in the case of Boston, 57% is added to the area accessible within one-half hour's travel by the application of electricity to street railways. While this practical study of actual conditions considerably modifies the comparison of relative speeds and of residence areas assumed by our contemporary, it does not upset its general conclusion of great gain to the public by the use of electricity.

◆

There is still another way in which the electric car has operated to build up suburban districts which is not alluded to by either Dr. Bell or the journal referred to above. We refer to the building up of manufacturing districts in the outskirts of cities where land for factories, yards, and warehouses, and for employees' dwellings can be had at a small cost, and where by means of electric railways the city itself is still within easy reach. Under the old conditions, it was difficult to induce workmen to leave the crowded city with its social attractions, and its opportunities for cheap purchases; and there were also disadvantages in locating a manufacturing establishment where communication with the business center was difficult. The electric car has removed both these obstacles, and the influence it has had in building up manufacturing suburbs is not the least of the benefits it has brought.

◆

A conservative view of the possibilities of utilizing garbage as a fuel for electric light stations is taken by Mr. Jos. Lobley, M. Inst. C. E., Borough Engineer of Hanley, England, in a recent report. Several of his main points are very much the same as some made by us in an editorial discussion of the subject in our issue of Aug. 26, 1897. Mr. Lobley urges that the total amount of power now required by the local electric lighting plant at Hanley is about 1,150 HP., and that this will soon be greatly increased. He figures on only 100 HP. as available from the refuse destructors, after satisfying the demands for power at the garbage plant. He proposes to install a generator at the proposed garbage plant for the generation of 100 HP. to be used for the day load on the electric station. The two plants cannot be operated together owing to the lack of a suitable site. Mr. Lobley conveys the idea that the only combined garbage burning and electric lighting plants actually installed in England thus far are the two at St. Pancras and Shoreditch. The St. Pancras combined plant shows for the year a cost per electric unit of 1.33d., against 0.76d. at another electric light station owned by the same authorities where no garbage is used. The conditions at St. Pancras, however, are said to be unfavorable for the combined plant. At Shoreditch results for anything like a year were not available when Mr. Lobley's report was written, but he points out that a large expenditure was made there for storing heat, which of course means heavy capital charges. One point made by Mr. Lobley is well worth quoting, as follows:

> Though the generation of electricity by steam raised by the burning of house refuse may have good economical results in certain places, I am inclined to think that the spare heat evolved will be better utilized in the future by improvements that may be brought about in the destruction, or preparing for destruction, of the refuse itself. In other words, this means that a given number of cells will do the work now performed by a greater number.

The remarks quoted appear to be especially applicable to this country, where less progress has thus far been made in reducing the fuel cost of garbage cremation than is the case in England,

Manufacturers who wish to do an export business must have their circulars and catalogues translated into foreign languages, but care should be taken that the translator is not only a good linguist, but also an expert in the particular business to which the documents to be translated refer. Otherwise the translation is apt to be a matter of ridicule to those to whom it is sent. We cannot well give an instance to show how an English circular might be translated into bad German, for example, but the London "Engineer" gives us the following illustration of a translation from another language into English which is probably no worse than many translations from English:

> "We pique ourselves," says the circular, "on making you known that the sale of the —— has, by us, undertaken. This preparated, exclusively arranged by some vegetables, is entirely spoiled about something hurtful to the steam boiler blades. By our preparated every calcarious substance is neutralized, reducing it to power, and at the same time steam boiler blades are conserved from the usual corrosion, not only, but the ebullition, is totally avoided, as it appears about some very interesting experiments, which have been made in several establishments." In conclusion the circular adds: "To be willing, this preparated may be decomposed."

◆

THE PREVENTION OF STEAMSHIP COLLISIONS.

The disaster to the transatlantic steamer "La Bourgogne," on July 4, by which 560 of her passengers and crew lost their lives, is the most serious marine disaster, with respect to the number of persons lost, that has occurred for many years. So far as we have been able to find, no such great loss of life has occurred in an ocean steamship accident since the White Star steamer "Atlantic" was wrecked on the coast of Nova Scotia, on April 1, 1873. The number lost on that vessel was almost the same as on the unfortunate "Bourgogne."

The terrible loss of life in this accident calls world-wide attention to the greatest danger which now attends ocean travel, that of collision, and to the possible means of guarding against it. The other dangers which formerly attended ocean travel have been greatly reduced by the stanch construction of modern steam passenger vessels, by the perfection which has been reached in propelling machinery, and by the extent to which navigation is now assisted by signals upon the coasts of all civilized countries. The danger of collision, however, has been greatly increased by the improvements in ocean navigation. In the days when the sailing packet was the fastest method of passenger travel by sea, collisions were almost unknown. It was not possible with sailing vessels to follow so closely the shortest route in a trans-oceanic voyage; and in a fog, when collisions usually occur, a sailing vessel is either stationary or moving slowly with light winds.

The danger of collisions is, in fact, almost entirely an outgrowth of the conditions of steam navigation. The number of vessels plying on the ocean has greatly multiplied, the size has been increased, they run in closely-defined routes, and most important of all, the energy stored in the swiftly moving bulk of a modern passenger steamship has become so enormous that her engines cannot check her headway till she has gone a long distance, and if she strikes another vessel the force exerted is so great that no construction that can possibly be devised can resist it without serious injury.

Of course much can be done, and is done, by the best steamship designers to reduce the dangers that result from any injury to a vessel's hull. The division of the hull into water-tight compartments, and the adoption of a bow projecting above the water-line to absorb part of the shock of a collision before the space below the water-line has to suffer, are examples of the methods adopted to reduce the danger of loss from collision. But water-tight compartments are not always water-tight. Bulkheads are essentially emergency constructions, not likely to be actually put to use in the entire life of the vessel. Naturally the tendency is to make them as light as possible. An experienced marine architect, not many years ago, expressed the opinion that a large proportion of ship bulkheads would be so strained as to leak badly if the compartment of the hull on one side were filled with water, and that adjoining were empty. If this is true of the uninjured structure, what are the probabilities when a ship has suffered such a shock as that which sent "La Bourgogne" to the bottom? Such a shock must inevitably strain every plate and rivet anywhere near the point where the blow is received. Doubtless improvements will be made in the hull construction; but there appears no reason to expect more than a trifling diminution in the dangers of collision on account of improvements in this direction.

We have alluded to the fact that steam vessels are able to keep very closely to the shortest route in sailing between two ports. It is manifest that this tends to bring two vessels sailing between the same ports, but in opposite directions, in danger of collision. In the case of the much-traveled path between the principal American ports on the Atlantic seaboard and the chief ports of England, France and the North Sea, the danger has become so manifest that most of the transatlantic steamship companies have agreed to use different routes for east bound and west bound vessels. It is stated that the French Line, to which "La Bourgogne" belonged, is the only one of these companies which did not join in this agreement. The ill-fated "La Bourgogne," when struck by the "Cromartyshire," on July 4, was not only about 160 miles north of the course usually taken in the summer by eastbound steamers from New York, but was from 60 to 90 miles north of the usual route of the west bound vessels. The route on which "La Bourgogne" was sailing is nearer the short, great circle course, it is true; but besides putting a vessel in the track of steamers proceeding in a contrary direction, the more northern route is much more subject to fogs and icebergs than the southern. It is probably safe to say that after the bitter lesson it has had, the French Line will conform to the general custom and send its vessels eastward on the usual course pursued by other vessels.

On the other hand, it is well to point out that the fixing of different routes for vessels sailing in opposite directions, important though it is, still leaves large risks of collisions unaffected. Naturally such a separation of routes will only be made in the case of the most traveled ocean lanes, and even where such a separation is made and observed, there is still chance of collision where the course is crossed by that of vessels sailing for other ports, and by vessels which are driven by stress of weather from the usual path, or which go astray in their reckoning.

Whatever blame may attach to the managers of the French Line, for adopting their present east bound course for their vessels, it seems to us that we shall be getting much nearer to the important cause of this terrible calamity if we emphasize the fact that the vessel at the time of collision was running at high speed through a thick fog. This disaster makes plain the risk that always attends this too common practice.

According to the best information, the ill-fated steamship was steaming at a speed of 17 to 18 knots when she collided with the "Cromartyshire," a sailing vessel which was drifting before a light breeze at a speed of only four or five knots, and which was hardly one-fourth the size of the big French liner.

It is a popular excuse for the maintaining of high speed in fogs, that it is really safer for the fast vessel to do so, as she will cut down anything she may run foul of with little injury to herself. The fishing schooners on the Newfoundland Banks have a well-founded hatred of the great steamships, which come flying through the fog at railroad speed, and which are believed to have sent many a sailing vessel's crew to a watery grave. But the sinking of "La Bourgogne" proves that the theory of making the Atlantic greyhound into a projectile to protect her from collisions does not always work. It was the French steamer's high speed and enormous momentum that caused her own destruction, when she fouled the drifting sailing vessel. With the experience of "La Bourgogne" fresh in mind, steamship companies can no longer claim that it is the safety of the great number of lives in their care that causes them to maintain high speed in fogs, notwithstanding the dangers in which other vessels are placed by their action.

It is fair to say, however, that in this matter the French Line is no more at fault than every other transatlantic steamship company, so far as we know. One has but to see the regularity with which these vessels come into port, notwithstanding the fogs that are so frequently encountered, to appreciate the fact that the so-called slacking of speed in fog really amounts to very little. When one considers the great distance which a vessel at a 15 to 17-knot speed will run before her reversed engines can absorb her headway, it is easy to see that for the fast liners to slow down two or three knots in a fog really accomplishes little in the way of added safety. It is said that in one recent case the Courts have held that a speed of 10 knots in a fog was excessive; and the decision seems in accord with sound engineering. If a high-powered steam vessel slows down to a speed of 7 to 8 knots in a dense fog, she can pretty surely be brought to a stop before striking a vessel ahead after the lookout first hears her signals. Vessels with less powerful engines, which take longer to check their headway, ought to run still more slowly in a dense fog, if the safety of ocean travel is to be fully ensured.

Notwithstanding these plain facts, it is not likely the steamship companies will change their practice as to high speed in fogs, even with the fatal accident to "La Bourgogne" as a warning. The public demands high speed; and it is quite doubtful whether a company which should advertise that all its vessels slowed down to 8 knots in thick weather would find its passenger lists increased thereby. The steamship companies are in business to give the public what it demands. They do not run steamers at high speed because of the freight they carry, but because of the passenger list. If the travelers on ocean steamships manifest a strong preference for slower and safer voyages, the companies will doubtless be found ready to meet the demand; such a change would mean, doubtless, a lengthening of the time schedules, to make allowance for possible or probable delays by fogs. Both for their own profit and the convenience of their passengers the steamship companies strive to move their boats with the greatest regularity. If a 7-day boat is delayed two days by slowing up for fog, it may not be possible to get her cargo removed and the new lading in in time for her start at the scheduled hour on the return voyage. But a lengthening of the time schedule, means fewer trips for a vessel during the season, and a reduction in its earnings.

Taking all these things into consideration, it does not seem probable that steamship companies will generally adopt the practice of running at a safe speed during fogs. We must look for greater safety, then, in the direction of improvements in the methods by which vessels approaching each other may be more surely warned of each other's presence.

The problem of making light rays penetrate a fog appears to be impossible of solution. A searchlight beam may, it is true, be seen for a considerable distance at certain times, when only a thin mist covers the water; but in such fogs as those on the Banks of Newfoundland, a searchlight beam cannot begin to reach as far as the present sound signals, and in daytime, of course, the searchlight is of no use at all.

As light waves cannot penetrate fog, we have left two possible directions in which to look for systems of signaling, by sound waves and by electric waves. The former of these is represented by the system now in use; but it is applied with a crudity which is amazing when one considers the great interests at stake. According to the present laws, steam vessels are required to sound a steam whistle at certain intervals, when enshrouded in fog, while sailing ships must ring a bell or blow a horn. The ineffectiveness of the average sailing vessel's fog warning is too well known to call for comment. On the other hand, the fog sirens, with which many light stations are equipped, can be heard for many miles out at sea, not alone because of their power, but because they are designed to concentrate the sound and project it in the desired direction.

The laws of acoustics are well known, and there is really no difficulty, not only in creating a sound of almost any desired pitch and volume, but in concentrating and directing it toward the quarter where the warning is needed. Under the present system nothing whatever is done in the way of directing the sound. In the case of the fog signal on ocean steamers, the fog whistle is usually located amidships, and the sound from it is radiated in all directions. Again, it is by no means certain that the discordant note of the steam whistle is the best form that a marine sound signal could take; some purer musical tone might penetrate quite as far and be more readily recognized.

We have alluded to the fact that electric waves can traverse a fog as well as sound waves. In the so-called system of telegraphing without wires, messages have been sent and received over a distance as great as 14 miles. It is quite within the bounds of possibility that two ships equipped with proper apparatus might be able to determine each other's presence and approximate position by means of electric waves alone, when both were enveloped in fog. We say it is possible; but it is a very far cry from this to any practical plan for the adoption of radiant electric energy as a fog signal for general use on board vessels.

An inherent defect in any such system, no matter how perfect it might otherwise be made, would be the necessity of skill and care in handling the instruments. Their derangement or failure to indicate correctly might be the source of disaster, and the same thing is true of any momentary lapse on the part of the operator. A danger signal that every man on board can see or hear is worth forty which require a skilled operator to watch a magnetic needle or a gold-leaf electroscope, whose indications attract no attention save from the one who knows their significance.

In dealing with matters of ocean navigation, it must be remembered that sailing vessels, large and small, as well as steam vessels, must be taken into account. It is visionary to expect that anything in the shape of complicated electrical appliances could come into use on vessels of this class as a fog warning, or that it would be so operated as to be effective if it were brought into use.

In conclusion, then, it appears to us that the best that can be done to reduce the danger of collision at sea is to improve the sound signals at present in use. If fast-running steamers wish to continue on their course in a fog with little or no checking of speed, let them provide themselves with some device at their bows that will project a volume of sound which will be audible for several miles ahead. Sailing vessels which are near enough to the course to hear this warning will be impelled to an instant reply with their own fog signals. It would be quite practicable for sailing vessels in such emergencies to discharge explosives which would produce a volume of sound that would reach the approaching steamer even if she were some miles away, and warn her to at once slacken her speed.

With such improvements in practice as respects the production of sound signals, might well come improvements in the system of listening for and detecting them. The "Eophone,"[*] by which the direction from which a sound comes is accurately located, is already in use on some American coasting vessels, and seems to deserve a more general adoption in steamship service; and it is quite possible that other inventions may make it possible to detect sounds at a greater distance than is possible with the unaided ear.

We are aware that it is exceedingly difficult to introduce anything in the shape of an innovation on board ship. There is no place where prejudice and conservatism have a stronger hold. But if owners of ocean vessels elect to risk the property and lives in their care by running at high speed in fogs, they ought to welcome every method by which the danger arising from this practice may be lessened.

Since the above was in type, we have received reports of the first day's proceedings in the official investigation of the accident. According to the testimony of the captain of the "Cromartyshire" in this inquiry, the whistle of "La Bourgogne" was first heard on board his vessel not more than ten minutes before the collision, and it was heard seven or eight times before the vessels came together. If "La Bourgogne" was going 18 knots, as claimed, this would indicate that the sailing vessel first heard the steamer when she was about three miles away. The lookout on board "La Bourgogne," however, is said to have heard the sailing vessel's foghorn only four or five times before the collision; and it does not appear that the engine was reversed, or even stopped, before the vessels came together.

If these statements are correct, our suggestion above, that sailing vessels ought to have some more efficient means of warning approaching steamers in a fog, appears to be especially appropriate to the circumstances of this disaster. It must be said, however, that if engines are not immediately reversed to check the headway of a steamer as soon as warning is heard of the proximity of another vessel, all the improvements in signaling systems that ingenuity can devise will be of small effect. We have tried to make it clear above that to run at high speed through a fog is and must always be dangerous. If steamship companies persist in taking this risk, however, they should certainly see to it that as soon as the signal of another vessel is heard, the engines are reversed to check the speed as quickly as possible. To pursue any other course is a sort of gambling with death that cannot be condoned.

LETTERS TO THE EDITOR.

Note on the Behavior of Some Cements With Diluted Hydrochloric Acid.

Sir: Having occasion recently to analyze certain cements, it was noticed that some on treatment with hydrochloric acid, gave off hydrogen sulphide, while others gave off free chlorine. In all seven cements were examined: four Portland and three natural cements. All were well-known brands and most of them had been tested with satisfactory results in the engineering laboratory of this university. It was found that all of the Portland cements gave off hydrogen sulphide, while all of the natural cements gave off chlorine.

It was assumed that the evolution of hydrogen sulphide indicated the presence of a sulphide or of a compound of the nature of the ultramarine pigment, and that the evolution of chlorine indicated the presence of a peroxide.

As neither a sulphide nor a peroxide appeared in the reports of analyses found in the literature consulted, it was thought worth while to determine the amounts of hydrogen sulphide and chlorine given off, respectively.

The following table gives the results, which are in all cases the average of well agreeing duplicates:

Portland.	Sulphur given off as hydrogen sulphide.	Correspond'g to calcium sulphide, (Ca S.)
Marked "La Farge"	0.05%	0.11%
" "Giant"	0.04%	0.09%
" "Alsen"	0.02%	0.05%
" "Belgian"	0.02%	0.05%
Natural.	**Chlorine.**	**Correspond'g to manganese dioxide (MnO_2.)**
Marked "N. Y. & Rosendale"	0.25%	0.31%
" "Hoffmann"	0.23%	0.28%
" "XXX Rosendale" .	0.20%	0.24%

Although the amounts of hydrogen sulphide and of chlorine are so small, one or the other could be detected in every case by the sense of smell, and by the usual simple chemical tests.

The Effect of Temperature on the Flow of Water Through Soils.

Sir: In connection with the letter in your issue of June 30, from Prof. L. G. Carpenter, upon the effect of temperature upon the flow of water through soils, I beg leave to call your attention to the formula which I have commonly used, and which was referred to in the editorial article in your issue of May 12. This formula is as follows:

$$\text{Temperature factor} = \frac{t\ (\text{Fahr.}) + 10}{60},$$

unity being taken as the velocity of flow at a temperature of 50° F.

In the following table are given the temperatures and velocity factors, as computed by Prof. Carpenter, from the formula of Poiseville, together with the temperature factors as determined by my formula, and also these last multiplied by 1.36, this being approximately the factor representing the difference between the standard temperature of 50°, which is taken as the basis of my formula, and the standard temperature at the freezing point, as in the formula of Poiseville. As the factors express only the relative flows at different temperatures and have no absolute significance, the introduction of a constant factor is unimportant.

Temperature, degrees, F.	Temperature factor, $\frac{t + 10}{60}$	Temperature factor, Multiplied by 1.36.	Factor as given by Prof. Carpenter.
32	0.700	0.952	1.000
42	0.867	1.179	1.195
52	1.033	1.405	1.403
62	1.200	1.632	1.625
72	1.367	1.859	1.860
82	1.533	2.085	2.109
92	1.700	2.312	2.372

It will be noticed that for temperatures between 42° and 82°, the differences between the two formulas hardly amount to 1%, and this is the range of temperature for which most calculations of this class are made. For temperatures but little above the freezing point my formula gives considerably lower results than the other.

I do not know upon what data the formula of Poiseville was based. My own was based solely upon experiments which I personally executed, with the flow of water through fine sands at carefully controlled temperatures, and the results were afterward checked by very numerous experiments upon the flow of water through long and fine capillary tubes under constant pressures and completely immersed in water kept at exactly the desired temperature. The results thus secured evidently followed the same law as the results obtained with sand, and were more accurate, owing to more perfect control of all the conditions, and were thus taken as the basis of the formula.

These experiments were carried out from the freezing point, with the whole apparatus packed in ice, to the highest summer temperatures. All of the results agreed very closely with the formula as given, and I am strongly of the opinion that it is very nearly correct for all temperatures between the freezing point and 100° F. I am also of the opinion that it applies to the flow of water through soils, or through long and fine passages. It applies also to fine gravels, as far as the rate of flow is influenced principally by the viscosity of the water. With coarse gravels and high rates other factors than viscosity exert controlling influences, and the temperature factor disappears.

Very truly yours, Allen Hazen.

St. Paul Building, New York, June 30, 1898.

A NEW FORMULA BY BAZIN FOR COMPUTING FLOW OF WATER IN OPEN CHANNELS.

In the "Annales des Ponts et Chaussees," for the fourth quarter of 1897, Mr. H. Bazin, Inspector General of Bridges and Roads, gives a new formula, for calculating the flow, or delivery, of water in open channels, which he believes is less complicated and of wider general application than those now in use. Space forbids our giving the full paper, with all its accompanying experiments; but the new formula and the reasons for deducing it may be briefly set forth as follows:

After discussing the difficulties besetting the problem of fairly meeting all conditions, Mr. Bazin says that the simplest, monomial formula is:

$$A = \alpha + \frac{\beta}{R} \qquad (1)$$

In which A is an abridgment of the relation $\frac{R\,I}{U^2}$, and α and β are two constants; in these and other formulas, R = the mean radius; I = the slope, and U = the mean velocity. The above formula was adopted by Mr. Darcy as the result of his experiments upon pipes, in 1850; and it answered well for pipes, by reason of the constancy of the transverse profile, always circular, and because of the relative smallness of the coefficiet β. But it is less applicable to open channels, owing to the diversity of profile and the nature of the sides causing α and β to vary within very wide limits. It must be admitted that this formula is open to a double objection. It provides for no relation between α and β, the last coefficient increasing very rapidly with the roughness of the sides; and, if we assume that the mean radius R increases indefinitely, A would be different for each kind of side. But it would seem, on the contrary, that if the width of a channel were increased while the sides remained identical, the inequalities of the sides should be gradually effaced as the dimensions of the bed increase. As a consequence, the values of A, for all the broad divisions of side roughness, should progressively approach each other and converge towards a common limiting point.

As it is impossible to find a simple relation between α and β, Mr. Bazin proposes, in Equation

---

[*] See Engineering News, Jan. 6, 1898.

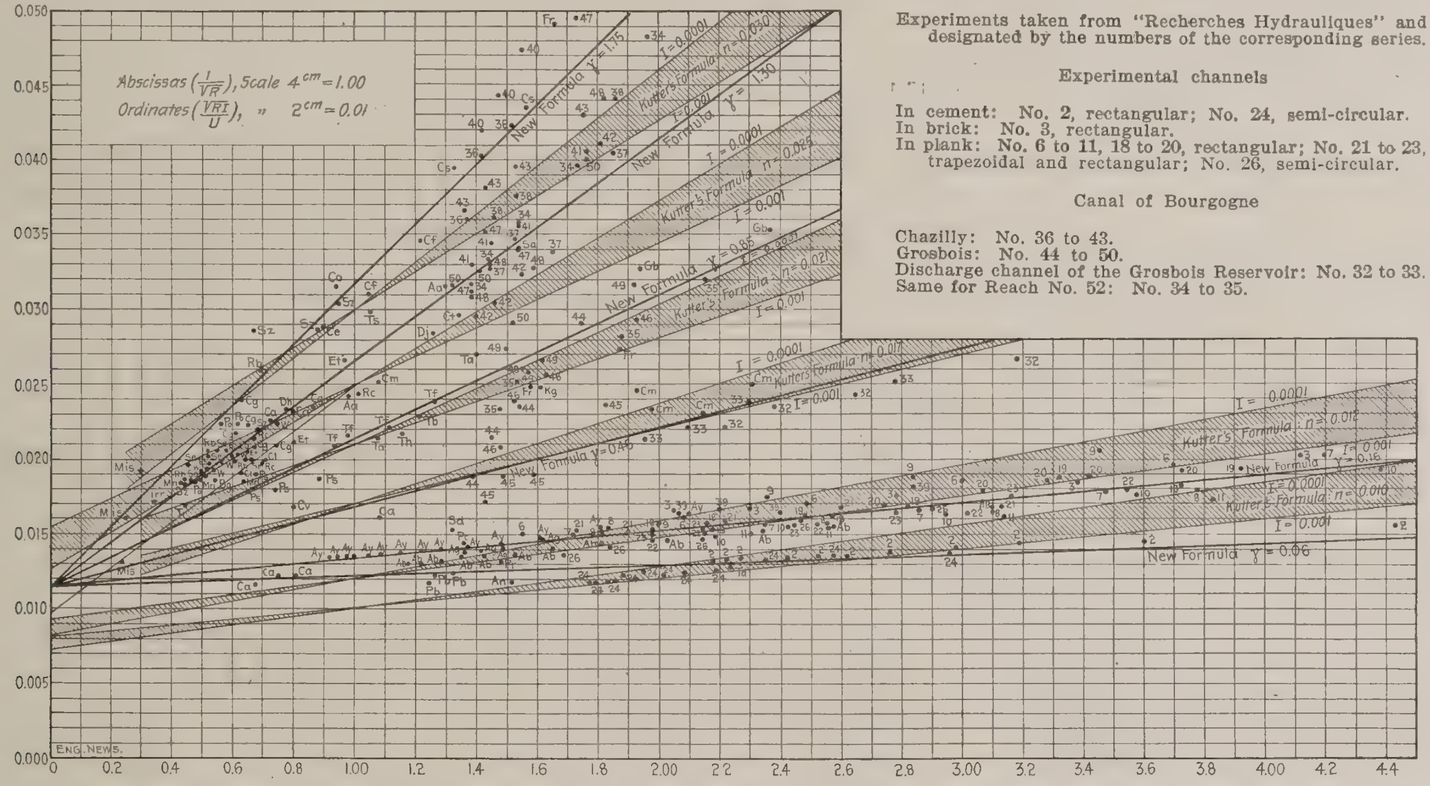
1, to replace A and R by their square roots, which vary less rapidly. He then has

$$\sqrt{A} = \alpha + \frac{\beta}{\sqrt{R}} \qquad (2)$$

We are enabled to obtain a sufficient approximation by assuming that α remains constant, and that the values of A, for the different states of the sides, always converge towards the limit α. The coefficient β then alone varies, becoming thus the characteristic of the degree of roughness of the sides.

In 1889, Messrs. Ganguillet and Kutter approached Equation 2 by writing it under the equivalent form of:

$$U = a\left[1 - \frac{b}{b + \sqrt{R}}\right]\sqrt{RI}$$



Experiments taken from "Recherches Hydrauliques" and designated by the numbers of the corresponding series.

They gave to a the constant value of a = 100, and attributed to b twelve different values, increasing from 0.12 to 2.44. But they complicated this simple expression by making its coefficients depend upon the slope I; and they did this to embrace some exceptional experiments made by Humphreys and Abbot upon the Mississippi River. Their definite formula, still much used in spite of its complication, is, in metrical measures:

$$U = \frac{23 + \frac{0.00155}{1} + \frac{1}{n}}{1 + \left(23 + \frac{0.00155}{1}\right)\frac{n}{\sqrt{R}}}\sqrt{RI} \qquad (3)$$

In this n is the coefficient of roughness. By making $23 + \frac{0.00155}{1} = K$, by an easy transformation, they wrote the formula:

$$\frac{\sqrt{A}}{n} - 1 = \frac{Kn}{1 + Kn}\left(\frac{1}{\sqrt{R}} - 1\right) \qquad (4)$$

Under this form $\sqrt{A}$ becomes equal to n and independent of the slope, when R = 1 meter. The factor between parentheses changes in sign, as R is inferior or superior to one meter, and the influence of the slope upon the value of $\sqrt{A}$ changes in the same degree and is not appreciable except for excessively slight slopes.

Returning to formulas 1 and 2, in admitting the first, we distinguish* four separate classes or types of sides, as follows:

1. Sides very smooth.........A = 0.00015 $\left[1 + \frac{0.03}{R}\right]$
2. Sides smooth ....A = 0.00019 $\left[1 + \frac{0.07}{R}\right]$
3. Sides slightly smooth......A = 0.00024 $\left[1 + \frac{0.25}{R}\right]$
4. Sides in earth ....A = 0.00028 $\left[1 + \frac{1.25}{R}\right]$

Admitting Equation 2, we would give to α the constant value 0.0115, in making β increase with the degree of roughness of the sides; from 0.0007, for very smooth sides, to 0.0150 for sides in earth.

The formula of Ganguillet and Kutter makes n vary between 0.010 and 0.025.

The comparison of the different formulas, as based upon given experiments, is graphically shown. If we take for the ordinates y the values of $\sqrt{A}$, and for the abscissas x the values of $\frac{1}{\sqrt{R}}$, the new formulas, as derived from the expression 2, would make,

$$y = 0.0115 + \beta x; \qquad (5)$$

or better still, if we designate by γ the ratio $\frac{\beta}{\alpha}$,

$$y = 0.0115\,(1 + \gamma x).$$

These would be represented by a number of straight lines all emanating from a single point ($x = 0$; $y = 0.0115$) situated on the axis of the ordinates. The inclination of these straight lines, measured by the angular coefficient 0.0115 γ, increases with the roughness of the sides. The Kutter formula for the same expression would be:

$$y = n + \frac{Kn^2}{1 + Kn}(x - 1) \qquad (6)$$

But instead of a single radiating bundle of straight lines, this expression would give for each value of n a separate bundle, departing from a variable point ($x = 1$; $y = n$). This set of bundles would be included between two straight lines corresponding to the two extreme values of I (I = OO; I = O), and having for angular coefficients, $\frac{23\,n^2}{1 + 23\,n}$ for the first, and n for the second; this last would pass through the origin. The inclination of all these lines, depending upon the term $\frac{0.00155}{I}$, increases just as I diminishes.

Not to complicate the figure given, Mr. Bazin only indicates the lines corresponding to the values I = 0.001 and 0.0001, except for the fourth type of roughness, where there has been added the very small slope I = 0.00004. The experiments referred to are represented by so many points, each having for co-ordinates the values of $\sqrt{A}$ and $\frac{1}{\sqrt{R}}$, corresponding to the particular experiment. These, however, are so numerous that the figure would become very confused if all were separately indicated; some, therefore, have been united to each other in groups, where the elements varied but little; and these are represented by a single point indicating the average of the group.

Mr. Bazin then goes on to the detail of the many experiments from which he deduces his new formula; but, as before remarked, space forbids entering into that part of his discussion.

---

*"Recherches Hydrauliques," Darcy-Bazin. 1865.

A MODERN ELECTRIC CENTRAL STATION.*

By George A. Damon.

The plant of the Imperial Electric Light, Heat & Power Company, of St. Louis, Missouri, is a good example of the present tendency in electric power station practice.

The territory to be supplied with electrical energy was a down-town district, and the character of the load to be expected included arc and incandescent lighting as required in stores, hotels, office buildings, and theatres, with more than the ordinary amount of motor work for elevators and light manufacturing establishments.

In planning an installation for a commercial enterprise of this character two conditions are imposed upon the designer. First, the service supplied the customer must be absolutely reliable. The second problem is to deliver to the customer electrical energy at the least possible cost, considering interest upon first investment, maintenance, and all other factors which enter into operating expenses.

The system which has been adopted as the one best fulfilling all the conditions in this particular case, involves the use of the direct current 220-volt incandescent lamp; the location of the station as near as possible to the center of distribution; the operation of generators capable of delivering current at a potential of 500 volts, a special arrangement of the generating units, and the installation of a storage battery in the plant to act as an accumulator, and also in parallel with the generators as an equalizer. The generators are run at a potential enough greater than 440 volts to overcome the line loss, and the motor circuits are at present operated at this potential. The storage battery across the outside mains allows 220-volt incandescent lighting feeders, to be distributed over the district.

The greatly reduced investment required for copper distributing feeders for a 220-volt system from that required by the usual direct current 110-volt system, the enlargement therefore of the territory which could be supplied, as well as the better quality of light and the possibility of operating 220-volt motors on the same circuits and thus making it possible to connect in many motors all ready in use in the city, were the main advantages which led to the adoption of the 220-volt lamp. The comparative lower efficiency and higher first cost of the lamp as compared with the 110-volt type was recognized, but these points are yielding to development, and it is thought that the difference between the two lamps in respect to efficiency and price is sure to become much less as the demand for the new lamp increases.

Local conditions made the location of the plant a much simpler problem than is usually the case. To have secured free water for condensation purposes would have removed the plant much too far from the center of distribution. The difference between drayage charges on the coal delivered to the station on its present site, and the cost of bridge tolls and switching charges which would have been necessary if the coal had been delivered directly from the cars, is only 15 cents per ton in favor of the latter plan, and this is not enough to justify the extra expense in feeders which would have been required to secure the location of the plant on a railroad switch. No doubt, therefore, was entertained in regard to the advisability, in this particular case, of carrying the fuel of the plant in wagons from the railroad to the station at the center of supply, rather than transmitting the product of the plant over copper conductors the same distance.

The advantages of supplying all classes of service from one type of generator, thus simplifying the distribution circuits as well as the arrangement of the station, and at the same time increasing the economy of the plant by reducing the amount of both fuel and labor required were not forgotten. At periods of light loads it is possible to furnish the entire output for incandescent lamps, arc lights and motors from one generator, while during the hours of minimum demand the load may be carried by the accumulator.

The battery acts in the same manner in carrying the peak of the load. This peak usually extends over a period of from one to three hours, and in an ordinary plant the equipment which is necessary to supply the extra demand at this time is inoperative during the remainder of the day. The storage battery auxiliary improves the unfavorable conditions, first, by evening up the load line, and thus increasing the efficiency of the generating plant, and second, by decreasing the total amount of investment required. The advantages of convenience and reliability of an accumulator in a central station cannot be questioned.

In the generating station proper every precaution known to modern practice has been adopted to deliver at the switchboard as much as possible of the energy originally contained in the fuel.

The engine room and the boiler rooms are upon the ground level, which arrangement ensures plenty of light, good ventilation, and convenience in operation. The engine room basement is used for the storage batteries, while in the boiler room basement is located the coal storage bin, the ash-handling apparatus, the piping, pumps, hot well and condenser. A second floor is added to the building for the offices of the company, for the storage of supplies and for a machine and repair shop.

The furnaces of the boiler are of the down-draft type. Considerations of availability and cost limit the fuel supply to coal from Southern Illinois mines, which produce a bituminous slack containing about 11,000 B. T. U. per pound. As the wagons deliver the coal directly on the boiler room floor, automatic coal-handling machinery was not thought to be a good investment.

Horizontal water tube boilers were adopted on account of their quick steaming properties, the comparatively small amount of floor space occupied by large capacities, their economy of fuel, and their safety under high steam pressures, the pressure adopted for this plant being 175 lbs. In determining the size of the boilers, due allowance was made for the fact that they were to be operated in conjunction with economizers, and their capacity was reduced accordingly. The question of economizers was thoroughly considered, and they were adopted only after careful estimates had been made, which demonstrated that the probable saving of fuel effected by their use would be sufficient to cover the usual allowance for depreciation, insurance, etc., and yet leave a very good margin for interest on the investment. As no steam-driven auxiliaries are to be used in the plant, there will consequently be no other feed-water heater besides the economizer. The economizer for each battery of two 375-HP. boilers consists of 320 pipes, and the heavy weight is carried on special iron framework which places the economizer at the back and above the boilers, as shown in the figure. The flue passages and stack connections are so arranged and fitted with dampers that the flue gases can pass either directly to the stack, through the economizer to the stack, or to the mechanical draft fan in series.

A mechanical draft fan is now considered by many engineers a necessary adjunct to a power station, and especially is this true if economizers are used. Unfortunately in this particular plant the city ordinances required a stack which would carry the gases up above the surrounding buildings. For this purpose a steel chimney has been built, but it is a disadvantage rather than a benefit as far as the question of draft itself is concerned.

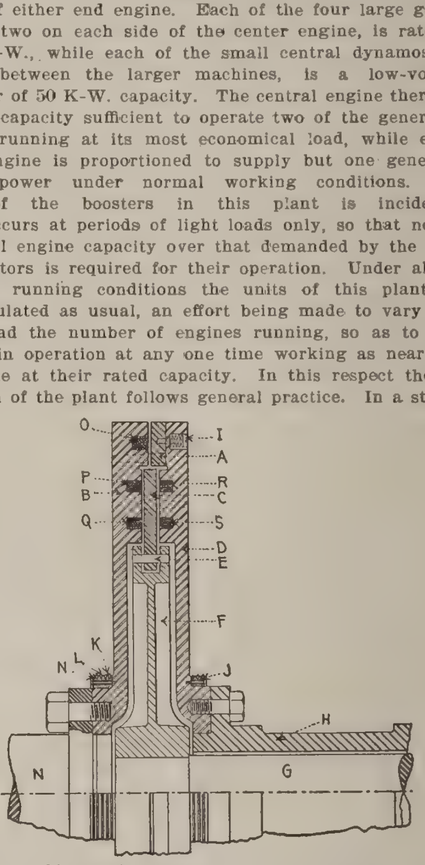
The engines are compound-condensing, and are the only steam using parts of the entire station equipment, all auxiliary apparatus being operated by means of electric motors. The steam thus passes directly from the boilers into the engines with a minimum amount of steam piping exposed for radiation losses. The steam from the engines exhausts into a surface condenser placed in the basement below the boiler room, from which, when condensed, it is pumped into the hot-well and through the economizers back into the boilers.

The condensing water is taken from the bottom of a cooling tower located upon the roof at an elevation of 50 ft. above the condensing apparatus. After this water passes through the condenser it is forced back to the top of the cooling tower by means of centrifugal circulating pumps. The water circuit is arranged so that the weight of the descending column is used to balance the weight of the ascending column of water. The work actually required of the circulating pump, therefore, is represented by the amount of power required to raise the water through the height of the tower, or about 30 ft., and the net result is the same as if the tower had been located on the ground level.

The plans for the completed station contemplate a total capacity of 5,000 K-W. There are at present, however, installed in the station but two engines, one of 750 HP. and the other of 1,500 HP. capacity. These engines are of the cross-compound marine type, of massive design, and run at a speed of 150 r. p. m. They are expected to develop an indicated horse-power hour on less than 14 lbs. of water per hour. Each engine is designed, however, to stand a continuous overload of 100%. This will be developed by means of admitting high pressure steam directly into the low pressure cylinder. The conditions under which it is expected to operate the engines in this manner will be referred to later. The cylinders are placed side by side, each piston acting upon a separate crank. Between the cylinders is located the receiver, which is provided with copper reheating coils. The high pressure cylinder is steam-jacketed on the barrel, and both cylinders have a steam-jacket on the heads. Both receivers and cylinders are protected with a non-conducting covering. Each engine is provided with a heavy flywheel located in the center of the frame between the cylinders. The speed is regulated by a shaft-governor operating an eccentric connected to the cut-off valves of the high-pressure cylinder, and in addition to this governor, each engine is provided with an additional automatic safety-valve, designed for the protection of the engine in case the speed should be abnormally increased for any reason. The engines also have a speeding device attachment by means of which they may be brought to the same rate of speed under frictional load as under full load.

The engines are directly connected to three 500-K-W. generators and two 50-K-W. boosters. These dynamos are of the multipolar type with ironclad bar wound armatures. Provision is made for sliding the field casting parallel with the shaft a sufficient distance to allow the field coils to be removed and the armatures reached for repairs. The brush holders are carried in a circular iron frame, arranged to be moved by means of a threaded rod and a hand wheel, so that the position of the brushes may be adjusted. An additional hand-wheel is provided for lifting the brushes from the commutator.

The engines and generators are connected by means of the "Arnold System." This system of power station design is well known, but its application to this particular station will be of interest. The general idea of the system is to improve upon the usual direct-connected unit principle by mounting each generator in such a manner that it can be operated by more than one engine. The line of engines and generators as they will eventually appear as the output of the station is increased contains three engines, the capacity of the center engine being 1,500 HP. and double that of either end engine. Each of the four large generators, two on each side of the center engine, is rated at 500 K-W., while each of the small central dynamos, located between the larger machines, is a low-voltage booster of 50 K-W. capacity. The central engine therefore has a capacity sufficient to operate two of the generators when running at its most economical load, while either end engine is proportioned to supply but one generator with power under normal working conditions. The use of the boosters in this plant is incidental, and occurs at periods of light loads only, so that no additional engine capacity over that demanded by the main generators is required for their operation. Under all ordinary running conditions the units of this plant are manipulated as usual, an effort being made to vary with the load the number of engines running, so as to keep those in operation at any one time working as nearly as possible at their rated capacity. In this respect the operation of the plant follows general practice. In a station containing independently-direct-connected units, however, if any piece of the generating machinery gets out of order, it disables the entire unit and thus the commonly accepted principle which underlies the selection of the size and number of units for a direct-connected station is to have in reserve and always ready to be put into immediate service, engine and generator capacity sufficient to take the place of the largest single unit in operation. Thus, with a station containing five generating units of equal size, the station capacity which may be safely relied upon is the combined output of but four of the units, the fifth unit being either held in reserve or undergoing repairs. An additional investment of 25% in station equipment over that actually required by the demands of the service is necessary, therefore, in this case, in order to ensure reliability. One of the advantages of the Arnold system of power-station construction is that the extra reserve unit is not required. Each generator is not rigidly connected to its corresponding engine but is in such a manner that it may be operated by more than one prime mover. Thus the central engine may run either one or all four of the generators as well as the two boosters, while the smaller end engines can reach either or both of two generators and also one booster.



Detail of Magnetic Clutch used in Arnold System of Connecting Engines and Generators in Power Station of the Imperial Electric Light, Heat and Power Co., St. Louis, Mo.

In the method of mounting and connecting the dynamos which makes this flexible arrangement possible each generator armature is mounted on a hollow shaft or quill, which is carried independently in its own bearings. The booster armature is attached to the solid shaft. This shaft is made of forged steel and extends through the hollow generator quills, but without touching them. It is by means of this shaft that any engine can reach the generators not contiguous to it; but under all normal operating conditions, this shaft does not turn, so that this system of connecting involves no more friction and requires no more lubrication than the ordinary arrangement. The coupling on the end of the shaft permits of three combinations: The engine may be directly connected with the quill of the adjacent generator, allowing the interior shaft to remain idle, or the solid shaft may be attached to either the engine flange or to the generator quill. The latter two combinations allow the transfer of power peculiar to this system.

The coupling or clutch is of particular interest, as it is said to be the first magnetic clutch applied upon a large scale to power station work. The accompanying cut shows a cross-section detail of this clutch. One part, B, is bolted to the engine flange, N. A corresponding part, D, is bolted to the generator quill, and this part carries an annular armature, A. Radial arms F, keyed to the solid shaft G. carry an interior armature C. Each coupling is provided with five circular coils of magnet wire O, P, Q, R and S. These coils are electrically connected to contact rings J, K and L, carried on insulating bushes bolted to the hubs of the clutch. Stationary brushes which are connected through a system of switches to the storage battery 'bus bars make it possible to send a current around any coil. The parts of the clutch containing the coils are made of cast-steel of high permeability, so that when a current is sent around any coil, the surrounding metal becomes a magnet and the armature facing the coil is immediately magnetically attracted. The two surfaces of the clutch parts being held in contact by a pressure of at least 80 lbs. per sq. in., it becomes possible to transmit power from one to the other. Thus to connect engine shaft N to generator quill H, a current is sent through coil O in that part of the clutch B attached to the engine shaft. Armature A, which is attached by means of strong studs to that part of the clutch which is securely bolted to the generator quill, is immediately attracted, and overcoming the small resistance of the spring I, the two parts become firmly attached to each other, making it possible to run the generator from the engine. If it is desired to revolve the interior shaft by means of the engine, the current is sent through coils P and Q in parallel, attracting armature C, while if the solid shaft is being turned by the other engine and it is desired to connect the shaft to the generator quill, then the coils R and S are energized and the armature C is attracted in the other direction. The circuits to these coils are all controlled by means of switches on the main switchboard. These switches are so arranged that when the circuit of any coil is broken, the discharge of the extra current is taken up through a carbon resistance, and the insulation of the coil is therefore protected from the liability to puncture. When the current in any coil is discontinued, spiral springs have been provided to overcome the residual magnetism and bring the armature back to its original position.

---

*Condensed from a paper presented at the 15th general meeting of the American Institute of Electrical Engineers, Omaha, June 30, 1898.

If both parts of the clutch which are to be attached are stationary, the connection becomes an easy matter, but if one part is revolving, it becomes necessary to put the other part in motion before the current is sent through the coils. This is accomplished by starting the dynamos as motors and bringing them up to speed before closing the magnet coil switch. For this purpose, regular starting-boxes have been installed, one for the boosters and the other for the generators, so that any machine may be thrown into or out of service directly from the switchboard. The result of the whole arrangement is, that a number of combinations between the engines and the generators becomes possible. Under all normal running conditions, the center engine will run its two adjacent generators, and the outside engines will operate the end generators. Each booster may be run when necessary, from either of two engines. The entire line of machinery may be connected together, so that all the engines and generators operate in unison as one large unit, the speeding attachment on the engines making it possible to operate them satisfactorily in this manner.

In case of accident to any generator that particular machine may be stopped without stopping its corresponding engine, and the electrical load will be immediately taken up by the other generators, but without overloading the engines. In case of accident to any engine, the ability of the other engines to carry an overload of 100% may be taken advantage of, if necessary, without overloading any of the generators. Thus the center engine is capable of carrying all four of the generators fully loaded, while the smaller end engines can operate two of the generators, if necessary, in case of a breakdown of the larger engine. The plant may, therefore, operate at period of maximum load, at its full rated capacity, depending entirely upon the advantages of the system of arrangement for a reserve in case of a breakdown to any part of the equipment.

All the variable speed motors operating the auxiliary equipment of the plant are designed to run at two voltages, the maximum being 440 volts, and the other voltage being one-half the maximum. Further speed regulation is obtained by changing the field excitation by means of a small resistance in the field circuits. The use of armature resistance is thus entirely obviated. A switchboard containing the switches and controling apparatus for the pumps and fan motors has been placed conveniently in the boiler-room and another auxiliary board has been placed in the engine-room to control the circulating pump and cooling-tower motors as well as the circuit leading to the crane which spans the engine-room. The use of economically controlled electric motors for running the pumps, fans and other auxiliaries of the plant is expected to result in a considerable saving of fuel.

The storage battery is located in the basement and has a capacity of 2,000 ampere-hours at the normal rate of discharge, but is capable of standing a discharge at the rate of 500-KW. for one hour. The station, therefore, as it now stands, can carry a maximum of 2,000-K-W., three-quarters of which can be taken care of by the generators, and the remaining quarter supplied by the battery. The battery consists of 280 cells, 100 of which are end or regulating cells, by means of which the potential may be regulated, the voltage depending, of course, upon the number of cells in circuit.

No radical departure is claimed for the design of this station. It has been described simply to show the latest solution worked out by conservative engineers of the problem of the generation and distribution of electrical energy. It is thought to be of interest because it presents a combination of the following widely discussed features of modern central station practice: (1) Improved furnaces; (2) Water-tube boilers; (3) Mechanical draft; (4) Fuel economizers; (5) Electrically-driven auxiliaries; (6) Cooling tower condensing system; (7) Arnold system of power station construction; (8) Battery auxiliary; (9) Two-wire distributing system, and (10) 220-volt lamps.

A STEAM ENGINE WITH OSCILLATING PISTON.

The engine illustrated herewith is somewhat of a novelty in steam engine design, and occupies a position midway between the ordinary reciprocating engine and the rotary engine. The cylinder has its axis parallel with that of the flywheel shaft, and in one end is the steam chest. The cylinder proper is divided into two compartments by a partition which is split along the middle to make room for the piston shaft. On this shaft are two pistons or wings which oscillate in the compartments, and on the end of the shaft is an arm carrying the connecting rod, no crosshead or guides being required.

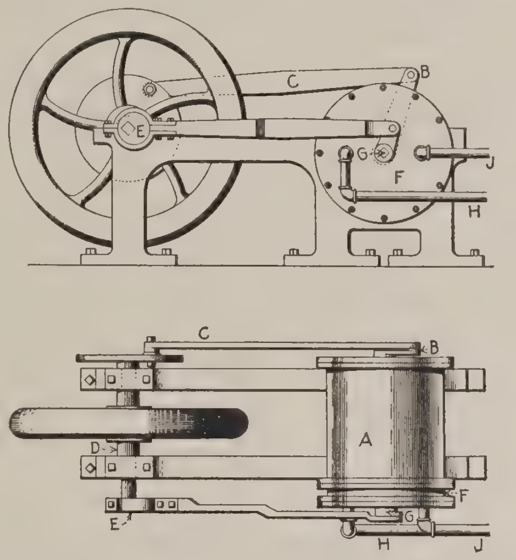


Fig. 1.—Elevation and Plan of Engine with Oscillating Piston.
Benjamin H. Trucks, Inventor.

Fig. 1 is a side elevation and plan of the engine, in which A is the cylinder, B a vertical oscillating arm on the piston shaft, which passes through the axis of the cylinder; C is a connecting rod which is attached to B and drives a crank disk on the flywheel shaft D. On the other end of this latter shaft is an eccentric, E, whose rod drives the oscillating valve in the steam chest F, this valve being carried to the stub shaft G, which is independent of the piston shaft. The steam pipe is shown at H, and the exhaust pipe at J.

its cover removed, showing the reciprocating pis-

Fig. 2 is an end elevation of the cylinder with ton K and the fixed partitions L, the inner ends of which are fitted with packing which bears against the piston shaft. Fig. 3 is an end elevation of the steam chest with its cover removed. In this view, M and M are the steam ports, and N, N the exhaust ports, while O, O are the exhaust passages leading to the exhaust pipe at J. Over these ports move two slide valves, P, P, Fig. 4, carried on the ends of a rocking bar Q, which is mounted on the stub shaft G. These valves have openings through which the exhaust steam from the cylinder passes to the passages O. In Fig. 4 only one of the valves is shown in position, in order to show the corresponding opening in the bar.

This engine is the invention of Mr. Benjamin H. Trucks, of Caldwell, Kan., who has had several built by P. I. Harris, of Wichita, Kan.; the L. P. Lester Machine Shop, at Newton, Kan., and the Ersham Machine Co., of Enterprise, Kan. The smallest, built merely as a working model, is of 2 HP., with cylinder 4 ins. diameter and 3 ins. long, the weight of the machine being only 68 lbs. The largest engine is of 15 HP., with a cylinder 8 ins. diameter and 6 ins. long, the piston area being 30 sq. ins. This engine weighs 750 lbs., and occupies a space only 24 × 44 ins. One of the larger engines is now at work driving the plant of the Enterprise Laundry, at Joplin, Mo., and has been in regular service since Feb. 23, 1897. The advantages claimed for this type of engine include reduction in friction and in number of parts, economy in steam consumption, and small floor space

THE INCREASE IN THE WORLD'S PRINCIPAL NAVIES.

Among the late reports of the Office of Naval Intelligence, in the U. S. Navy Department, is one by Lieut.-Commander W. H. Driggs, U. S. N., on "The Increase in Naval Strength" of England, France, Germany, Russia and Japan. At a time when additions to our own navy are being looked upon with especial favor it is interesting to note what other nations are doing in this direction, and for this reason we make a brief abstract of the paper of Lieut.-Commander Driggs.

England, as always in naval matters, is far in the lead. The budget voted for 1897-98 amounts to about $107,000,000, providing for an expansion in all branches of the navy. The number of officers and men has been increased from 88,850 in 1895 to 100,050 in 1897, including in these figures the coast guard. The total of ships under construction and to be built during the fiscal year of 1897-98 is 108, including 14 battleships, 8 first-class cruisers, 9 second-class cruisers, 10 third-class cruisers and 52 torpedo boat destroyers.

Russia is not only adding to her naval strength but is also actively engaged in opening up harbors and channels for strategical purposes and establishing naval bases in foreign countries. The naval program that was mapped out in 1896 involves an expenditure of $318,000,000, though the exact number of ships contemplated is not specified by Lieut.-Commander Driggs.

France in her budget for 1898 asks for $55,108,000 for naval purposes, allotting nearly $20,000,000 of this for new ships. Her present building program extends over a period of eight years, and involves an expenditure of about $144,300,000. Like Russia, she is providing for better harbors and channels at home, and is creating bases for supply and repair in foreign waters. Admiral Besnard, the French Minister of Marine, calls especial attention to the need of fast cruisers in modern naval warfare, and to emphasize his demand for additional ships of that class in the French navy he presents two tables showing certain naval conditions in May, 1897, as follows:

Available.	England.	Triple alliance.	Russia.	France.
First-class cruisers	24	3	5	8
Second-class cruisers	61	26	7	12
Dispatch boats	50	19	20	13
Torpedo-boats and torpedo-boat destroyers.	51	38	9	13
Total	195	86	41	46
Under construction.				
First-class cruisers	12	10	6	5
Second-class cruisers	6	3	1	7
Dispatch boats	10	5	0	1
Torpedo-boats and torpedo-boat destroyers.	14	1	1	3
Total	42	19	8	16

In addition to the above France had in 1897 10 battleships and 7 armored cruisers under construction, and, counting all classes, she had 65 war ships under construction in that year.

Germany is now putting into execution a naval program laid down in 1873 and deferred until the present time for lack of funds. This program calls for an active fleet of 17 battleships, 8 armored coast-defense ships, 9 large cruisers and 26 smaller cruisers. In addition, she proposes a reserve fleet of 2 battleships, 3 large cruisers and 4 small cruisers. The total proposed and those classed as available by the German government are shown in the following table:

	Total authorized.	Available.
Battleships	19	12
Armored coast defense	8	8
Large cruisers	12	10
Small cruisers	30	23

Germany recognizes the fact that to maintain a modern fleet she must provide for the replacement of old-type ships. To this end she fixes the period of efficiency of battleships and armored coast-defense ships at 25 years, of large cruisers at 20 years and of small cruisers at 15 years; after these periods of service they would have to be replaced by others of the newest type. The personnel of the German navy is to be raised from 18,138, its present strength, to 26,637 in 1904.

Japan has a naval program to be completed in 1906, and during this period she proposes to spend $102,396,546. This program calls for the addition to her navy of the following vessels: Four battleships of 15,000 tons, 4 armored cruisers of 9,500 tons, 3 second-class protected cruisers of 4,800 tons, 2 third-class protected cruisers of 3,200 tons, 3 torpedo gunboats of 1,200 tons, 11 torpedo boat destroyers and 89 torpedo boats. Prior to her war with China Japan only had 18 cruisers ranging from 1,500 to 4,000 tons. When those authorized are completed she will have a navy of 65 ships of war, 11 torpedo boat destroyers and 115 torpedo boats. Japan now has 1,725 officers in her navy exclusive of midshipmen and sub-lieutenants.

In the above lists the total proposed expenditure for naval purposes, according to adopted programs, amounts to $1,001,690,000, all to be expended before 1906 by five nations only.

TEST OF A PIPE DISTRIBUTION SYSTEM.*

By James S. Haring, M. Am. Soc. C. E.†

In testing the distribution system of a water-works recently designed and constructed by the writer, some peculiar facts were developed which have not as yet been satisfactorily explained.

In 1896 a new system of pipes, ranging in size from 12 to 4 ins., and in length about 10½ miles, were constructed. The work of laying the pipes began in May, and was completed in the following December. At the time the work was progressing provision was made for placing hydrants, but they were not then contracted for, and their T-connections were closed by a temporary plug, as were also some dead ends.

The pipe contract was awarded to one of our most reliable pipe companies. The specifications were the usual provisions for a test of 300 lbs. hydraulic pressure per sq.in , and to be sharply rapped with a hammer while under such pressure. No inspector was placed at the foundry, the pipe being taken under the company's guaranty. We had an inspector examine the pipe while being unloaded and again go over the pipe after being hauled to its position on the street; finally, it was inspected by the contractor's men when being laid. The same course was pursued with regard to the manufacture of the valves, each valve being tested at the factory to 300 lbs. internal pressure, the contract for which was also given to one of the largest manufacturers. About 175 valves were used in the mains, and 70 in setting hydrants as supplemental valves.

The contracts for laying the pipe and setting the hydrants had specified that a test of 200 lbs. per sq. in, should be made.

The territory covered was that of a side hill ranging in elevations from 0 to 250 ft., the reservoir being at an elevation of 352 ft. A temporary connection was made between the main leading from the reservoir and the system tested by means of a 2½-in. fire hose connected with a hydrant nozzle.

The test was under the charge of a foreman who had been an inspector on the pipe laying and hydrant setting, a man of more than ordinary intelligence, carefulness, and honesty in the performance of his work, and a man who had also been for a number of years a foreman in one of the largest foundries doing fine metal work, in the East. This inspector not only brought experience, but energy and trustworthiness to bear in the performance of his duties, and when he reached a conclusion it was reliable and could be depended upon.

The pipes were filled with great care; about two weeks were taken to accomplish this so that no hammer or compressed air would occur. Each hydrant was opened and left open to allow the escape of air as it was found the water was rising to near its level, until it ran out of the hydrant; blowoffs were opened and all dirt and accumulations gotten out of the pipes until we were satisfied that every precaution had been taken to make a proper test.

The means of testing were those usually employed, a boiler feed pump set in a galvanized sheet-iron 10-gallon can bolted through the bottom to a plank, the pump connected with an inch galvanized iron pipe and valve by a union to a special hydrant nozzle cap. Water was supplied to the can from a barrel filled from the hydrant before connecting the pump. Attached to the other hydrant nozzle was a test gage registering up to 200 lbs. pressure (this was afterwards changed to a gage registering up to 400 lbs., for the peculiar reason that the contractor who set the hydrants claimed that we were going over 200 lbs. in our test, and were thereby causing the various leaks which appeared in his work, and were violating the terms of his contract by excessive pressures); the sensitiveness of this gage was not very delicate and caused us some annoyance.

The test was begun at the bottom in small sections and from this proceeded slowly over the whole system. There being no service connections, the work was very much simplified. First the reservoir test was made by shutting off all supply; the pressure was noted for a few minutes, when the pump would be applied and a pressure maintained by closing the globe valve from the pump. All defects were sought for and corrected in each section as found.

The very liberal use of valves in the system made it possible to cut off small sections and to locate defective valves, the defect consisting generally of some obstructions under the disk. The writer at the beginning found considerable trouble on one section; the action of the gage convinced him it was not a leak, but must be a defective valve; after manipulating numerous valves, he located the trouble on one immediately at the corner where the test was being made. After digging up the valve and taking off the dome fully a pound of gravel, sand and part of a tin can were found in it.

We were able to make the hydrant test separately because of the supplemental valve with all but two joints, and the hydrant itself separated from its connection. The hydrant was the first test, then the whole to the valve, and finally the pipe section with such enlargement of it as was desired, or found advisable.

As a charge was to be made against the various contractors doing the work of furnishing materials, each was notified of the test to be made and the date when it would begin. Only the contractor who set the hydrants, a local man, responded.

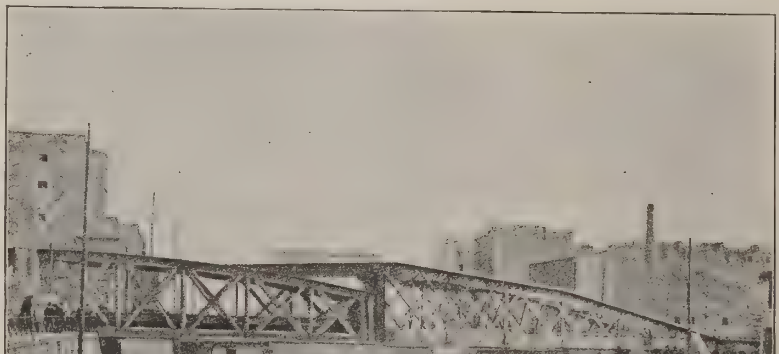

FIG. 1.—THE ERECTION OF A BRIDGE OVER THE NORTH RY., PARIS; VIEW OF OPENING SPANNED BY MAIN AND PILOT TRUSSES.

The test demonstrated only nine minor defects in pipe laying, the cost of repairing which amounted to $89.39. But the pipe demonstrated the peculiarities of the situation, and it in turn was surpassed by the strange defects found in the valves. Three breaks occurred in the 12-in. pipe, two in the 8-in. pipe, and two in the 6-in. pipe, the cost to repair which amounted to $237.49. The fracture in this pipe was, in every instance, shown by the pipe to be inherent foundry defects, cold shorts, honeycombed shrinkage, and foundry imperfections.

After the foundry test, after the care of inspection and every precaution, why should these pipe fail under a 200-lb. pressure test?

Now as regards the valves. The writer required in the valves supplied for the mains the use of sheet rubber gaskets, but in the hydrant valves that provision was not made, and the ordinary oiled paper was used for gaskets. Of the 175 valves used in the mains, 19 were found to be leaking around the packing gland gasket; of the 67 hydrant valves then placed, 13 gaskets were defective, the total cost of making good the defects being $152.33.

What caused these leaks is one of the excuses for bringing this paper to your attention. Our claim is that the general cause was that the gaskets were too thin, that the iron surfaces were compressed together without sufficient elastic material to shut off fully the space between their faces and also that in two instances the follower of the packing gland was too large to enter the casting.

The valve manufacturers made a careful examination of our claims, and disputed their liability for the damage, and they claimed:

(1) That we had not properly conducted the test, having compressed air in the system which had found its way out through the gaskets of the valves as the points of least resistance.

(2) That if the air had not been compressed in the system, it had been in the domes of the valves, thereby causing the gaskets to blow out, and that the air pressure would amount under such conditions to more than 200 lbs.

(3) It was claimed that the packing gland nuts had been tightened up when they were inspected in May, 1896, and that the gaskets had shrunken so that the nuts again needed tightening.

When we produced the gaskets, in each case tagged as to locality, and found none of them showing the least signs of having been blown out, no explanation made by them seemed to account for the cause.

That the leaks were very large from this cause, we demonstrated to the personal examination of a representative of the company who happened to be present when one of the leaks made itself evident.

It is claimed by the makers of these valves that no similar experience has ever come to them in a matter of this kind; of the many thousand of valves sent out by them none have ever been found defective in the two ways discovered in this case. They claim that with their shop practice and system of testing valves, that no such defects could be afterwards found; yet they were, and they are indisputable.

---

[*] Abstract of a paper prepared for the Buffalo meeting of the American Water-Works Association, June, 1898. Owing to the inability of the author to be present, the paper was not read, but it was ordered printed in the proceedings.

[†] Engineer of Water Commissioners, Nyack, N. Y.

THE ERECTION OF A BRIDGE OVER THE NORTH RAILWAY IN PARIS.

Owing to increased traffic across the sunken tracks of the Chemin de fer du Nord, in the XVIII. Arrondissement of Paris, the railway company was lately required to construct another bridge for street traffic at this point. The method of erecting, or rather of launching this bridge over the eight or ten tracks of the railway has been described by "Le Genie Civil," and from this description the following abstract is made:

The mean span between the faces of the bridge abutments was 132 ft.; the bridge floor was on a slight grade and the minimum free height above the tracks was 17 ft. The bridge itself was a riveted bow-string truss, 50.84 ft. wide between centers of trusses, and tied together by cross-girders spaced 13.74 ft. apart. The floor was made of longitudinal beams and buckle plates, supporting two footways of 10 ft. each, and the roadway proper 29.52 ft. wide. This floor was paved with wood upon a beton base and the footways were covered with a coating of asphalt ¾-in. thick. The metallic part of the bridge in place weighed 995,720 lbs. and cost erected $47,085, or not quite 5 cts. per lb.

Owing to the traffic upon the tracks beneath, and their peculiar arrangement, it was deemed impracticable to erect this bridge upon the usual timber falseworks; and the engineers of the railway company decided to erect the bridge upon the ground, at one side of the opening, and then to move the whole structure forward to its destined position. As it was a single-span bridge it became necessary to provide the bridge with an advance or pilot truss. This pilot had a total length of 87.94 ft., and it weighed 110,000 lbs. Acting as a concentrated load, this weight centered at a point 36 ft. beyond the point of connection of the two trusses. The extreme forward end of the pilot truss was slightly curved upwards to permit the truss to more easily slide upon the forward rollers. The pilot truss was constructed with a slight grade, designed to compensate for the general deflection during the operation of launching. The two trusses were connected by riveting together the abutting end members and by struts extending back upon and riveted to the upper chords of the bridge proper, as shown in the illustrations; the bottom of the joint between the two bridges was covered by steel plates. The two main trusses of the pilot were firmly united by a system of horizontal and vertical bracing.

The bridge proper was erected in such a position that the pilot truss could be built and attached to it, with the nose of the pilot resting upon rollers on the near abutment. These rollers were 23.58 ins. diameter, made of cast steel, and they were arranged in four groups of six rollers each under each truss, on the launching side of the opening, and one group of four rollers under each truss on the far side of the opening. These rollers rested in pivoted supports of cast steel, carried by balance beams supported in turn by "Belleville" or pivot washers on beams on the ground. All of these rollers were so placed that the lower chord of the bridge was upon a uniform down grade of 63.4 ft. per mile. The actual grade of the bridge in position was 126.7 ft. per mile, or twice this grade; but the reduction was made for the purpose of greater safety in launching.

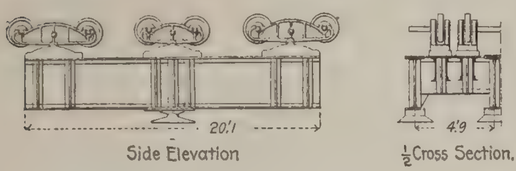

Fig. 2.—Roller Supports Used in Erection of a Bridge.

The bridge was moved forward upon the rollers by two windlasses, placed behind the bridge and each operated by eight men. From the drums of these windlasses two chains passed under the bridge, over pulleys attached to the farther abutment, and then back over two other pulleys attached to the rear of the bridge, with the ends of the chains fixed to the nearest abutment.

After every detail of the proposed operation had been carefully tested, the launch was made in two days, Aug. 23 and 24,. On the first day work was commenced at 9 a. m., and it was stopped, according to the program arranged, as soon as the pilot-truss had entirely cleared the rollers on the near abutment. The launching was resumed at 7 a. m. the next morning, and the truss proper was rolled across the opening by 11 o'clock, without interruption of traffic on the railway or trouble of any kind.

In place for launching the total weight of the bridge was 877,800 lbs., on a length of 143.9 ft. The total length of the pilot truss was 87.94 ft. and it weighed 110,000 lbs. As a result, the uniform distributed load of the main truss was 6,100 lbs. per lin. ft. and that of the pilot truss 1,251 lbs. per lin. ft. The work was done from the plans and under the direction of M. Boreux, Chief Engineer of Public Ways and Lighting, of Paris.

The actual cost of this pilot-truss and its manipulation is not stated in the article in "Le Genie Civil," nor does the author say what was finally done with this expensive and seemingly wasted material. It is safe to say that an American engineer, with a problem of this kind on his hands, would have made use of timber which can be used again. With eight or ten tracks at his disposal, one or more could certainly have been thrown out of service long enough to build a central wooden tower or pier; and this tower could have been utilized as a midway roller support for the pushing out of the counter-weighted main truss. Or, the same tower could be used for erecting two 70-ft. temporary wooden spans, upon which the bridge proper could either have been erected or rolled out complete. If headroom were lacking, the main bridge could have been built above grade and lowered into place upon the abutments.

THE COST OF PRODUCING POWER AT THE LACHINE RAPIDS ELECTRIC POWER PLANT.

The Lachine Rapids power plant, a full description of which was given in our issue of Feb. 18, 1897, has now been in operation about eight months, although all of the turbines and electrical generators have not as yet been installed. This plant, it will be recalled, utilizes a portion of the water power of the Lachine Rapids of the St. Lawrence River about 7 miles above Montreal. The rapids proper are about 5 miles long, with a fall of 30 ft. The Lachine Rapids Hydraulic & Land Co. built a dam about one mile from the foot of the rapids and a dike parallel with the bank and some 5,000 ft. long, which together give the company about 15,000 cu. ft. of water per second with a head of 11 ft.

Taking the plant as it now exists and as it is at present operated, Mr. W. McLea Walbank, managing director of the company, deduces some interesting figures which he presented in a paper read before the National Electric Light Association at its convention held at Chicago in June. The cost of distributing power is not considered since it would be the same no matter how the current was generated, and the figures given consider only the cost of generation and transmission to the sub-stations in Montreal.

The cost of all water rights, dams, wing walls, power houses, hydraulics and electric generating and transmitting machinery installed to the present time amounts to $957,200. This includes a power house, dams, etc., sufficient for the maximum output (about 14,500 HP.), although the present hydraulic machinery and generating apparatus has a capacity of only 4,000 K-W. at the generator switch-board. Allowing a loss of 10% for transmission, the present generator plant can deliver at the sub-station for customers' use 3,600 K-W., and taking the investment at $957,200, this corresponds to a first cost of $263.83 per kilo-watt.

To determine the total cost per kilo-watt an estimate is made as follows:

Interest on $263.83 at 6%, per K-W	$15.95
Depreciation, 5% on $300,000 (taken as the value of that portion of the plant of 3,600 K-W. subject to depreciation), = $15,000, or per K-W	4.17
Operating expenses, including labor, repairs, insurance, etc., for 3,600 K-W., per K-W	2.85
	$22.97

This gives a total cost of $22.97 per K-W. per year for continuous service.

Considering the plant completed and all machinery installed as planned, there will be 72 turbines in operation, and the plant will represent an investment of $1,113,273. At that time the output after deducting all losses will be 13,500 K-W. delivered at the sub-station, and the investment per kilo-watt of such output will be $82.46. As in the former case:

Interest on $82.46 at 6%, per K-W	$4.95
Depreciation at 5% on the increased value of depreciable property but distributed over 13,500 K-W., per K-W	1.68
Operating expenses, also increased but now spread over 13,500 K-W., per K-W	1.51
	$8.14

On this basis the cost per K-W. per year for continuous service will be only a trifle more than one-third of what it is at present.

If the above figures for the cost of power are compared with the cost of steam power at Montreal, where steam coal costs about $3.50 per ton, it will be seen that the company can market its power at a good profit and still make a large saving to its customers over the cost of power or electric current produced by steam.

◆

THE RECLAMATION OF THE SAND-DUNE territory of the Pacific Coast, at Golden Gate Park, near San Francisco, is carried on as follows: The shifting sand is first seeded with sand-grass (Arundo arenaria) and this is allowed to grow for two years; by this time the ground is sufficiently held in place to permit the planting of the Monterey Pine and Cypress, and these trees, in two or three years, complete the reclamation. The entire cost of reclamation does not exceed $50 per acre, and out of the 1,040 acres in the park, 500 acres are now planted with the pines.

◆

A LARGE FLEXIBLE WOVEN SUCTION HOSE, for a centrifugal pump dredge, has been made by George Angus & Co., of Newcastle-on-Tyne, for use in the dredging of sand bars by the Natal government. The pipe is 42 ins. diameter and 10 ft. long, and is made of 1-in. best yacht Manila rope, extra soft laid. To keep the tube in shape iron hoops, 1½ ins. diameter, were woven into the circumference at intervals of less than 1 ft. The same firm has just shipped a similar suction pipe to East London, Cape Colony. This latter pipe is 27 ins. diameter, with 1⅛-in. hoops 30½ ins. apart at the top and 8 ins. at the bottom of the pipe, and the pipe was 9 ft. 8 ins. long and woven on a curve of 10 ft. radius.

◆

MEASUREMENTS OF STREAM FLOW in California in 1897 gave the following main results:

River.	Daily flow, sec.-ft.* Maximum.	Minimum.	Mean.	Total, for year, acre-ft.*
Sacramento[1]	89,100	4,600.0	12,482.0	8,912,617
Stanislaus[2]	10,580	140.0	1,835.0	1,319,333
Tuolumne[3]	14,700	28.0	3,364.0	2,422,827
San Joaquin[4]	18,600	60.0	3,105.0	2,248,979
Kings[5]	22,732	250.0	2,933.0	2,129,964
Kings[6]	18,900	208.0	2,115.0	1,533,288
Kern[7]	5,342	260.0	1,234.0	893,055
Little Rock Creek[8]	308	0.2	25.0	17,979
San Gabriel[9]	1,765	18.0	130.4	93,169
Santa Ana[10]	585	29.0	86.6	61,524

Gaging Stations: [1]Red Bluff, [2]Oakdale, [3]La Grange, [4]Herndon, [5]Red Mountain, [6]Kingsburg, [7]Bakersfield, [8]Palmdale, [9]Azusa, [10]Warm Spring.

*1 sec.-ft. equals 50 California's miner's-inches. 1 acre-ft. is the amount necessary to cover one acre 1 ft. deep, or 43,560 cu. ft.

The measurements were made by the United States Geological Survey, of which Mr. Chas. D. Walcott is director. We are indebted for this information to Mr. J. B. Lippincott, Resident Hydrographer for California, 412 Byrne Building, Los Angeles, Cal.

◆

THE CARR AUTOMATIC MACHINE GUN, invented by Howard Carr, of San Francisco, was lately tested in that city. The gun is fired from a tripod and weighs 20½ lbs. complete. It uses the Krag-Jorgensen cartridge and is fed by a detachable magazine containing 310 cartridges and weighing about 25 lbs. The gun itself is described as "an ordinary Krag-Jorgensen barrel, automatic breech-action, with pistol-grip." In the test noted it was used as a single shot, and then with the continuous fire at the rate of 600 shots per minute. The San Francisco Arms Co. control the patents.

◆

A NEW ENGLISH SERVICE BULLET has been adopted and will be first used in the Egyptian campaign now in progress. This bullet is the same in general form as the Lee-Metford bullet; .303-in. diameter, 1⅕-in. long and weighing 215 grains; it thus fits all the service rifles and machine guns. The case is nickel, with the lead filling the base only and leaving the conical end empty. When this bullet strikes, the conical end burrs and opens backward, lessening the penetration and increasing the shock. Cordite is used for propelling it, and while it is only half the weight of the old Martini-Henry bullet of 410 grains, it has as much energy as the latter with the old service charge of powder. The new bullet is being made at the Woolwich Arsenal at the rate of 2,000,000 rounds per week. If it proves satisfactory in the Khartoum expedition, a permanent stock will be kept on hand at Woolwich.

◆

THE TRANS-SIBERIAN RAILWAY, according to U. S. Consul Smith, of Moscow, has cost, in the five years, 1893 to 1897, inclusive, $188,014,938. In addition to the above, $5,978,663 has been spent for topographical and astronomical work, irrigation, surveys, geological study, agricultural instruments, etc., connected with the development of the country adjacent to the railway.

◆

WESTINGHOUSE AIR-BRAKES, in value ranging from $2,000,000 to $3,000,000, have been ordered by the Russian government for the Manchurian Railway; and there is a prospect of this contract being doubled in the near future, according to U. S. Ambassador Hitchcock, of St. Petersburg.

◆

CUBAN RAILWAYS, says the U. S. Consular Reports, for July, 1898, aggregate about 1,000 miles of main line, not including private branch lines to all important sugar estates. The most important company is the Ferrocarriles Unidos, with four lines connecting Havana with Matanzas, Batabano, Union and Guanajay. The Western Railway extends to Peurto de Golpe, 96 miles from Havana, and 10 miles from Pinar del Rio, the center of the tobacco district. The other lines join the towns of Cardenas and Santa Clara; Mantanzas and Murga and Matanzas and Guareiras; Concha and Cruces; Cienfuegos and Santa Clara; Caibarien and Placetas, Puerto Principe and Nuevitas, and the Guantanamo railway. A line, 8½ miles long, also connects Havana with Marianao. There are four cable lines connecting with Cuba, but only Havana, Cienfuegos and Santiago de Cuba are connected with these lines. The International Ocean Telegraph Co.'s cable runs from Havana to Florida; the Cuban Submarine Co. has a cable connecting Havana with Cienfuegos and Santiago de Cuba; the West Indian & Panama Co.'s cable connects Havana with Santiago de Cuba, Jamaica, Puerto Rico, the

Lesser Antilles, Isthmus of Panama; the Compagnie Francaise connects Havana with Santiago de Cuba, Haiti, Santo Domingo, Venezuela and Brazil.

◆

THE NILGIRI RACK RAILWAY, now being built in India, starts from the Meltapollyam Station, on the Madras Railway. The alinement is nearly straight for 4½ miles to the foot of the hills, at Kulhar Station, with easy curves and a steepest grade of 1 in 40. From Kulhar, which is 1,250 ft. above sea-level, to Coonor, 5,600 ft. elevation, the line rises with a grade of 1 in 12½, with curves as sharp as 328 ft. radius and 70% of the whole line in curve. On this railway there are 35 plate-girder bridges of 60 ft. span and 44 bridges of shorter span; the Burliar bridge has five 60-ft. spans and is 120 ft. above the water in the gorge. Most of these bridges are on curves of 328 ft. radius and on the steepest grade of 1 in 12½. The rack-bars, 10 ft. 2¾ ins. long each, are stamped out of steel. The four tank engines to be used were built by Bezer, Peacock & Co., and weigh 33 tons each, with 13 tons on driving axles, and 10-ft. rigid wheel-base. Each engine will pull 90 tons on the 1 to 40 grade, and 60 tons on the 1 to 12½ grade, and both engines and cars are fitted with powerful brakes. It is proposed to later carry this line over the hills to the port of Calicut, on the west coast of India, and to make connection with the meter-gage railways to the east.

◆

BRAZILIAN MANGANESE ORE has been exported for the last four years. It comes from the district of Miguel Burnier, State of Morias Geraes, about 310 miles from Rio Janeiro. The mines are about 4,000 ft. above sea level, and they are worked by Italian and native labor. In 1897, the entire output of 8,800 tons went to Philadelphia. An analysis of the ore shows an average of 54.7% of metallic manganese, 0.021% sulphurous acid, and 0.077% of phosphoric acid.

◆

A NEW PROCESS OF OBTAINING GREAT HEAT, in metallurgy, is described in "Stahl and Eisen" by Mr. Hans Goldschmidt. The process is based upon the utilization of the high temperature disengaged in the combustion of aluminum. The body to be heated is wrapped in an envelope made of a mixture of aluminum and metallic oxides in a pulverized state. This is then exposed to a temperature sufficient to decompose the oxides and burn the aluminum; and the interior of the packet is very rapidly raised in temperature with results comparable to the work of an electric furnace. The process appears to be especially applicable to the reduction of chrome. On account of the chemical effects resulting, we can substitute for the oxides, or oxidizing bodies, sulphur or sulphureous bodies. The aluminum may also be replaced by magnesium or carbide of calcium.

◆

A MATCH PASTE, free from white phosphorus, and which will light on cloth or other substances, is wanted by the Belgian government, which offers a prize of 50,000 francs to the inventor. The competition is international and is open until Jan 1, 1899. M. Woesti is the President of the Adjudicating Commission, and his address is 2 Rue Laterati, Brussels.

◆

COAL TESTING BY THE RONTGEN RAYS is a new application suggested by H. M. Couriot in a communication to the Paris Academie des Sciences. He states that carbon, in all its forms, is exceedingly transparent to the rays, while silica and silicates are opaque. By placing a lump of coal between a Crookes tube and a fluorescent screen, all the slag and clinker forming parts of the fuel can be detected. In this manner M. Couriot has tested anthracite and bituminous coal, lignite, coke and block fuel. The conglomerate character of the latter fuel is clearly shown; and in coke the particles of iron sulphide show as black spots on the screen. Rough lumps of coal, 1⅛ to 2 ins. thick, may be used, with an exposure of 5 minutes and with a coil having a 10-in. spark.

◆

THE COPPER PRODUCTION of the world for four years, 1894-1897, inclusive, is given in two tables in "The Engineering and Mining Journal" of June 25, from which we extract the following, the figures being tons of 2,240 lbs.

	1894.	1895.	1896.	1897.
World's production	324,859	334,268	381,109	412,050
Production in the U. S.....	163,394	177,881	214,149	227,763
Consumption in the U. S...	84,267	125,619	102,083	126,438

◆

THE VALIDITY OF THE PATENT of C. J. Van Depoele, No. 424,695, April 1, 1890, for improvements in suspended switches and traveling contacts for electric railways, now owned by the General Electric Co., was sustained on June 23, 1898, by the U. S. Circuit Court, Eastern District of New York, and a perpetual injunction was decreed against the defendants. On Jan. 8, 1896, the U. S. Circuit Court of Appeals reversed a decision of the lower court against this patent, and remitted the case to the Circuit Court with instructions in favor of the complainant. The patent covers broadly the switch in overhead wires for electric railways, now in universal use. Two of the sustained claims are as follows:

3. The combination, with an overhead wire for receiving an underneath contact, of a switch-plate attached to the wire in about the same horizontal plane as the wire.
4. The combination of a track having switches, an overhead conductor above the track and having switches, and a car on the track provided with a contact-carrying arm arranged to engage the conductor at a point in rear of the front wheels of the car.

◆

THE GREATEST DANGER of a severe loss by fire in a factory insured in mutual insurance companies, according to the report of the Boston Manufacturers' Mutual Fire Insurance Co. for the month of May, is the possibility that some valve in the automatic sprinkler service will be closed at the time when a fire breaks out. That this danger is not a slight one is shown by the fact that the company's inspectors during six months found 48 instances of sprinkler valves being wholly or partly closed, which ought to have been open. To avoid this source of danger it is recommended that all sprinkler valves should be sealed or strapped open and that each mill manager shall require an inspection and report upon the condition of the valves to be made once a week, such reports to be kept on record for revision by the inspectors of the insurance companies.

◆

HOT-AIR MOTORS are discussed in "Dingler's Polytechniches Journal," for April 10, 1898. In attempts to improve existing machines Messrs. Lombaerde and Lecompte, of Paris, replace the air-compressor by an annular space around the motor cylinder itself. Mr. Korndoerfer, of Bohemia, is striving to maintain tightness and the lubrication of the cylinder at high temperatures. Mr. Ledin, a Swiss, proposes to employ as a motor-fluid a mixture of steam and the products of the combustion of petroleum in a closed vessel. Messrs. Rozer and Mazurier have patented a device for combining a hot-air and explosion motor, in such manner that the escaping gas of the one heats the air in the other motor.

◆

THE COLONIAL POSSESSIONS of European states are given as follows in "Consular Reports" for June:

Country.	Area, sq. miles —(1 = 1,000.)—		Population —(1 = 1,000.)—	
	Motherland.	Colonies.	Motherland	Colonies.
Great Britain	121	16,662	39,825	322,000
France	204	2,505	38 520	44.290
German Empire	209	1,616	53.325	7,450
Portugal	36	810	5.050	10,215
Holland	13	783	4.930	34,210
Spain	198	405	17,300	9,800
Italy	111	242	31,290	195
Denmark*	15	87	2,175	130

*Including Faroe Islands, Iceland and Greenland.

BOOK REVIEWS.

PHYSICAL GEOGRAPHY OF NEW JERSEY.—By Rollin D. Salisbury. With Appendix by Cornelius Clarkson Vermeule. Vol. IV. of the Final Report of the State Geologist. Cloth, 6½ × 10 ins.; pp. 170 + 200; 24 plates, 37 figures in text, large map in tube, and many tables. Address John C. Smock, State Geologist, Trenton, N. J.

This volume contains some of the matter given in the first volume of the present series, "Topography, Magnetism and Climate," which is now out of print. Part I. of the main work is devoted to a detailed description of the topography of the state, and Part II. to the history of the topography. The illustrations are made up of maps, diagrams, profiles and reproductions of photographic views, all well designed to aid in a ready understanding of the text. We have rarely seen a selection of views in a work of this kind which so truly illustrate the text, as distinguished from embellishment. These views do both. The colored relief map is on a scale of one mile to the inch, and is a very creditable piece of work.

The appendix contains a variety of useful information, mostly in statistical form, but conveniently arranged. Among this information may be mentioned bench-marks; elevations of prominent points and topographical features; drainage areas, forested areas and population of stream basins; areas and drainage areas of lakes and ponds and areas of tidal waters; yield of streams; areas of counties and townships; and detailed results of a magnetic survey of the state.

MONOGRAPH UPON RESERVOIRS AND THEIR EFFECTS ON THE FLOODS OF THE MISSISSIPPI SYSTEM.—By James A. Seddon, U. S. Assistant Engineer. Washington, Government Printing Office. Paper; 9 × 6 ins.; pp. 26. Maps and diagrams.

This monograph is the result of long and laborious investigation on the part of the author, and is based upon existing facts, instead of being a deduction from assumed or supposed conditions. For the Upper Mississippi System the period of study covers the years 1880-1885, inclusive; and for these years the stages and discharges of the Mississippi, Missouri and Ohio Rivers have been observed and plotted so as to show the combinations that make up the final floods at Cairo. A similar study covers the floods of the Lower Mississippi, for the years 1882-83-84, 1892-93, and 1897. This gives the stages and discharges at points of maximum outflow and inflow, from Cairo to Vicksburg, and shows the free and restrained outflow and the resulting changes. The map accompanying the flood data indicates the levee lines and distances subject to overflow, and the areas of the several swamp basins. From the material here made available, Mr. Seddon is enabled to, at least, approximately estimate the capacity of reservoir required for a given reduction of any flood; and to do this both for the Upper and Lower Mississippi systems. As to the Upper System, Mr. Seddon concludes that if any head water reservoirs are to be established with the view of reducing flood extremes at Cairo, this must be done wholly in the Ohio River basin; and before any intelligent estimate can be made of the ultimate effect of such reservoirs, the discharge data for this river must be more closely studied and subdivided and traced back to its sources.

The Lower Mississippi has an immense reservoir capacity in its swamp overflow; but these are of little value, as they are, for reducing or controlling flood levels. This lack of value does not arise from any want of capacity to take off water; but from their inability to hold it until after the flood period has passed. The author then suggests a system of cross levees, cutting the natural drainage area into a series of shallow reservoirs, with outlets under control. He discusses the question fully and generally estimates the capacity to be given to such a chain of reservoirs. The detailed location and dimensions he leaves for further consideration.

THE ALASKAN GOLD FIELDS AND THE OPPORTUNITIES THEY OFFER FOR CAPITAL AND LABOR.—By Sam. C. Dunham. Bulletin of the Department of Labor; Carroll D. Wright, Commissioner; No. 16. May, 1898. Washington: Government Printing Office. Paper, 9×6 ins.; pp. 297 to 507. Large map of Alaskan gold fields and smaller maps of particular localities.

To obtain trustworthy information relating to the opportunities for remunerative employment of American labor and capital in the Alaskan gold fields, Mr. Sam. C. Dunham, of the U. S. Department of Labor, was sent out to make an official investigation. He left Washington, D. C., on July 31, 1897, and his report brings matters up to Jan. 8, 1898. He commences his report by a brief account of the discovery of gold in this region; describes the four principal trails leading to the Yukon gold fields, and then presents in the form of a diary, the details, cost and incidents of his trip from Dyea to Dawson. This part of the report is of exceeding value to the would-be gold-seeker; for it tells him what to expect and how much each step towards the Yukon may cost him, in cash and in personal effort. He was exactly one month in reaching his destination; or, from Aug. 23 to Sept. 23, 1897. The separate gold fields are then taken up in detail and illustrated by maps of each. The report is so full of detail that it is impossible to generalize with profit to the reader; but Mr. Dunham freely quotes from and recommends as the best book yet written on the Yukon country, Mr. Wilson's "Guide to the Yukon Gold Fields," published in 1895.

A few facts of general interest may, however, be noted. The mean annual temperature of the Yukon Valley is roughly estimated at 23° F.; with 78° below zero as the greatest cold on record. Open water, even in the coldest weather is found on many of the tributaries of the Yukon, and many springs never freeze over. The annual rainfall in the valley is figured at about 25 ins., with 60 to 70 ins. on the coast. May, June and part of July bring delightful weather, on the lower Yukon; but the rest of the summer is very wet. Timber is abundant; the most valuable and largest tree being the white spruce, which attains a height of 50 to 100 ft., and a diameter of one to two feet. As indicated by annular fiber, this tree attains an enormous age; a tree 8 ins. in diameter often showing rings indicating 600 to 700 years of growth. This slow growth, due to climatic conditions, eliminates any hope of a new timber growth of any consequence when once the present timber supply is exhausted. The other more common trees are the birch, balsam poplar, willows and alders. The first is the only hard wood in the country, and the others are usually soft, rotten and valueless. The Yukon Valley has abundant capacity for producing root crops; but it is not yet known that oats, barley, wheat or rye, can be cultivated. It is highly improbable that this territory will ever become a self-supporting agricultural district; and its chief wealth lies in its fish, furs and gold.

The Yukon River itself is formed by the junction of the Lewes and Pelly rivers, and taking the first as its main source, the river is nearly 2,600 miles long. A number of steamers are now operated on this river, during the navigation season of four to five months, and the head of navigation is at Fort Selkirk, 2,210 miles above the mouth. The fare from St. Michaels, 60 miles across the bay from the Yukon mouth, to Dawson, 2,050 miles up the river, is $90. The up-stream freight, of which there is very little, is figured on a basis of 53 cts. per ton per running hour; and the down-stream freight at 55 cts. These figures mean $150 and $70 per ton respectively, between St. Michaels and Fort Selkirk. On the lower river, or 600 miles above the mouth, driftwood is entirely depended upon for fuel for the steamers, as all standing timber has been cut away by the ice coming down the river. But there is an abundance of good coal, further up, near Tawana, Circle City and Forty Mile. But the interested reader must obtain this report for himself to benefit by the patient work of Mr. Dunham; and the large folding map of the region contained in the report is essential to an intelligent study of the material which he presents.

BIDS FOR TRANSPORTING THE 25,000 SPANISH prisoners at Santiago de Cuba to Spain were opened in the office of Col. F. J. Hecker, U. S. Volunteers, in the Army Building, New York, July 20, at 11 a. m. The United States Government will deliver the prisoners at Santiago, and it asked proposals for a per capita price for transporting officers and men from Santiago and delivering them on shore at some Spanish port. Cabin accommodations must be provided for the 1,000 officers and the men are to receive the regular U. S. Army ration. Ships must report at Santiago between July 30 and Aug. 10, and payment will be made on satisfactory evidence of the landing of the prisoners in Spain. The following bids were received:

(1) New England Chemical & Supply Co., Boston, Mass., bid $890,000 for the transportation of 1,000 officers and 24,000 enlisted men. Officers to have cabin accommodation; enlisted men to be given steerage quarters. Transportation to be under any other flag than that of the United States.

(2) L. A. Thieme & Co., Philadelphia, Pa., offer to carry 25,000 Spanish soldiers to Spanish soil for $385,000.

(3) James W. Elwell & Co., New York, N. Y., offer the steamship "Meustria," with accommodations for 1,000, at $35 a head for enlisted men and $75 each for officers.

(4) William H. Thompson, New York, N. Y., offers a steamer to carry 150 officers at $90 each, and 1,400 enlisted men at $45 each.

(5) George Osgood Lord, New York, offers to carry 24,000 enlisted men at $37.50 each and 1,000 officers at $72.50 each. Another bid was also received from him which was not considered, owing to its not conforming to the terms of the advertisement, in which the United States was to provide blankets and rations for the prisoners.

(6) Thomas L. St. John bid $37.37 each for officers and $24.87 each for men, including subsistence.

(7) Joint bid from Anchor Line, represented by Henderson Brothers, New York; Cunard Line, represented by Vernon H. Brown & Co., New York; Leyland S. S. Co., represented by Sanderson & Son, New York; Hamburg-American Packet Co., New York; Wilson & Furness-Leyland Line, represented by Sanderson & Son, New York; North German Lloyd S. S. Co., represented by Oelrichs & Co., New York; Royal Mail Steam Packet Co., represented by Sanderson & Son, New York; Robert M. Sloman & Co., represented by Emil Boas, New York, bid as follows: $110 for officers, who are to be given cabin accommodations; $55 for enlisted men, to be carried in the steerage; payment to be made on the number embarked, without regard to whether the vessel reaches port safely or is lost.

(8) C. B. Richards & Co., New York, offer two ships: "Spartan Prince," to carry 40 officers at $55 each, and 800 enlisted men at $25 each.

"Tartar Prince," to carry 50 officers and 1,000 enlisted men at the same rates. A second offer from the same firm tendered its services as agents to arrange for the transportation; this proposition was not considered.

(9) Davis & Huger offered to furnish from one to fifty steamships of foreign build. The offer was not accepted as it did not conform to the terms of the advertisement.

(10) The Tweedie Trading Co. offered bids in triplicate for three ships, with a total carrying capacity of 3,000 men, at a charge of $29 each for enlisted men and $50 each for officers.

(11) R. A. C. Smith, New York, offered to carry enlisted men at $30 each and officers at $60 each on steamers of the Spanish Transatlantic S. S. Co., sailing under the Spanish flag, the United States to guarantee safe conduct. The Washington authorities will award the contract later.

THE LOG OF THE U. S. BATTLESHIP "OREGON," on her now famous run from Puget Sound to Florida, is thus filed in the U. S. Navy Department:

Port.		Record of run.		Average knots per h'r
Left.	Arrived.	knots.	hours.	
Puget Sound, March 6.	San Francisco, March 9	826	72	11.48
San Francisco, March 19.	Callao, April 4	4,112	375	10.96
Callao, April 7.	Tamar, April 16	2,550	214	11.9
Tamar, April 17.	Sandy Point, April 17	131	9	14.6
Sandy Point, April 21.	Rio Janiero, April 30	2,148	221¼	10.16
Rio Janiero, May 5.	Bahia, May 8	749.7	74¼	10.09
Bahia, May 10.	Barbadoes, May 17	2,228	191¼	11.54
Barbadoes, May 19.	Jupiter Inlet. May 24	1,666	141½	11.27

The total distance from Puget Sound, in the Pacific, to Jupiter Inlet, on the Atlantic Coast of Florida, was 14,511 knots, and the ship consumed on this trip 3,909 tons of coal. The total running time was 1,298.25 hours; and the average hourly rate of speed for the entire trip was almost 11.2 knots. According to the above record the coal consumption was almost exactly 3 tons per hour of actual running time, auxiliaries and consumption in port being included, however, in the total.

PROGRESS ON NEW WARSHIPS is reported by Chief Naval Constructor Hichborn, to July 1, as follows: Battleships "Kearsarge," 61% completed; "Kentucky," 61%; "Illinois," 48%; "Alabama," 61%; "Wisconsin," 40%. These five battleships are all to have a maximum contract speed of 16 knots. Of the ten torpedo boats under construction, the "Rowan" and "Mackenzie" report 99% completed; the "Davis," 94%; the "Farragut" and "Fox," 88%; the "Dahlgren," 80%; the "T. A. M. Craven," 60%; the "Stringham," 35%; the "Bailey," 21%; and the "Goldsborough," 10%. The submarine torpedo boat "Plunger," at Baltimore, is within 73% of completion.

◆

THE COMPAGNIE TRANSATLANTIQUE or French Line of steamers, made, on July 3, a contract with the French government for ten years beginning in 1901. After 1901 the company is required to make 52 round trips per year to New York at an average speed of at least 20 knots per hour. The company is now building at St. Nazaire two new steamships which are to have a guaranteed speed of 22 knots per hour, and are to cost about $3,000,000 each. The "La Lorraine" will be ready in 1900, and "La Savoie," three months later. In 1903 and 1905, two more ships, faster still, are to be ready for service.

◆

AN OCEAN LINER LARGER THAN THE "KAISER Wilhelm der Grosse," of the North German Lloyd, is reported to have been ordered by the Hamburg-American Line of the Vulcan Shipbuilding Co., of Stettin, to be completed in 1900. The vessel will be 685 ft. long, 66½ ft. beam and 44 ft. deep. The "Kaiser Wilhelm" is 648 ft. over all, with 66 ft. beam and 43 ft. depth.

◆

THE MORGAN LINE has contracted with the Newport News Shipbuilding and Dry-Dock Co. for three freight steamships, to cost about $2,500,000 in all. These vessels will be built of steel, with single screws, and will generally resemble the "El Rio" and her sister ships now in the government service. They will each measure 5,000 tons gross, be 400 ft. long, 50 ft. beam and 35 ft. deep. They will have three decks, be provided with water-tight bulkheads, have steam heat, electric lights, etc., and triple expansion engines of 4,000 I-HP., with boilers carrying 165 lbs. of steam. The propellers will be 18 ft. diameter and the average speed is to be 17 knots. The Newport News Co. is also building two vessels for the Cromwell Line; and two are being built for the Old Dominion Line at Chester, Pa.; all intended to replace vessels secured by the government.

◆

BIDS FOR TWO FLOATING DOCKS are asked for by the U. S. Navy Department, the cost not to exceed $250,000 for both. Docks ready built are wanted, as there is need for them now in Cuban waters, and two such docks are located in New York and three are in and about New Orleans. The bids for the larger floating docks, provided for in the late naval appropriation bill, will be called for within a couple of weeks.

THE OUTER BREAKWATER LIGHTHOUSE, in New Haven harbor, Conn., will be put under contract on Aug. 1, 1898. This lighthouse will consist of a circular cast-iron caisson foundation 36 and 33 ft. diameter and 58 ft. high, sunk by the pneumatic process and filled with concrete. The depth of water is 28 ft. to M. H. W., and the caisson will be sunk into the sound for 8 ft., and then surrounded by rip-rap, 18 ft. deep. The upper 10½ ft. of the foundation pier will be lined with brick work and forms a cellar, covered by the main-gallery floor supported on brick arches. This will be surmounted by an iron dwelling house, 18 ft. diameter at the base and 45 ft. high to the focal plane. A covered gallery, with a diameter of 38½ ft., will surround the first story of the four in the dwelling portion. This gallery will be accessible from the water by ladders and a spiral iron stairway, inside, leads to the lantern. This light will be located some distance outside the entrance to the harbor, with the focal plane 61 ft. above Mean High Water. Lieut. Col. D. P. Heap, Engineer Corps, U. S. A., Lighthouse Engineer, Third District, Tompkinsville, N. Y., is the engineer in charge.

◆

THE EXTENSION OF THE WEATHER SERVICE to the Caribbean Sea is now before President McKinley in the form of a draft of an order, and an appropriation of $75,000 to be used at his discretion for this purpose. Negotiations are now in progress with other governments interested and whose consent will be necessary in locating stations and providing observers. The scheme contemplates stations on the islands of Trinidad, Curacoa, Martinique, Hayti, the Barbadoes and San Domingo. There are now operating stations at St. Thomas, at Kingston, Jamaica, and at Havana. The Mexican government is also establishing a line of stations along the Mexican Gulf coast to Yucatan, and these are being fitted with instruments adjusted to U. S. standards. With the proposed belt of stations daily weather reports would cover the entire coast line of the Gulf of Mexico and Caribbean Sea for the benefit of the commerce of all nations.

THE EXPORT TRADE OF THE UNITED STATES, for the fiscal year ending June 30, 1898, amounted to $1,231,311,868, an increase of $180,300,000 over the preceding year. The imports for the same year were valued at $616,052,844, a decrease of over $148,600,000 as compared with 1896; the balance of trade in our favor was thus $615,259,024 for the fiscal year. For the month of June, 1898, the exports were valued at $94,808,263, or an increase of over $21,600,000 over the same month of the preceding year. The imports of gold coin and bullion, in the last fiscal year, amounted to $115,173,988, against an export of only $15,324,929.

A PERMANENT EXHIBITION OF MANUFACTURES is proposed for New York city, under the direction of the Merchants' Association of New York, an organization having as its object the fostering of New York city's trade. The scheme contemplates the erection of a suitable building and the placing in it of a large and attractive collection of manufactured articles. It is further contemplated to establish similar exhibitions in a number of European commercial centers. A meeting will be held Oct. 1, details of which will be announced later, to organize a company for this purpose.

◆

THE SCARCITY OF TIN ORE IN THE WORLD is pointed out by Geologist B. G. Skertchley, of Australia, in a published monograph. He shows that while known gold fields cover 1,500,000 sq. miles of the earth's surface, the located tin fields have an area of only 12,500 sq. miles. The seven tin districts of Europe produce about 8,300 tons yearly, with 8,000 tons of this credited to the Cornwall mines. Asia has two tin districts; Hunan, in China, said by some to yield 10,000 to 20,000 tons annually, but proven to yield less than 2,500 tons per year; and the tin mines of the Straits Settlements and adjacent territory, the richest in the world, yielding 58,000 tons yearly. Africa has no known tin mines; North America has no paying mines; South America mines less than 4,000 tons per year, in Bolivia and Peru, and Australia contributes about 6,000 tons a year.

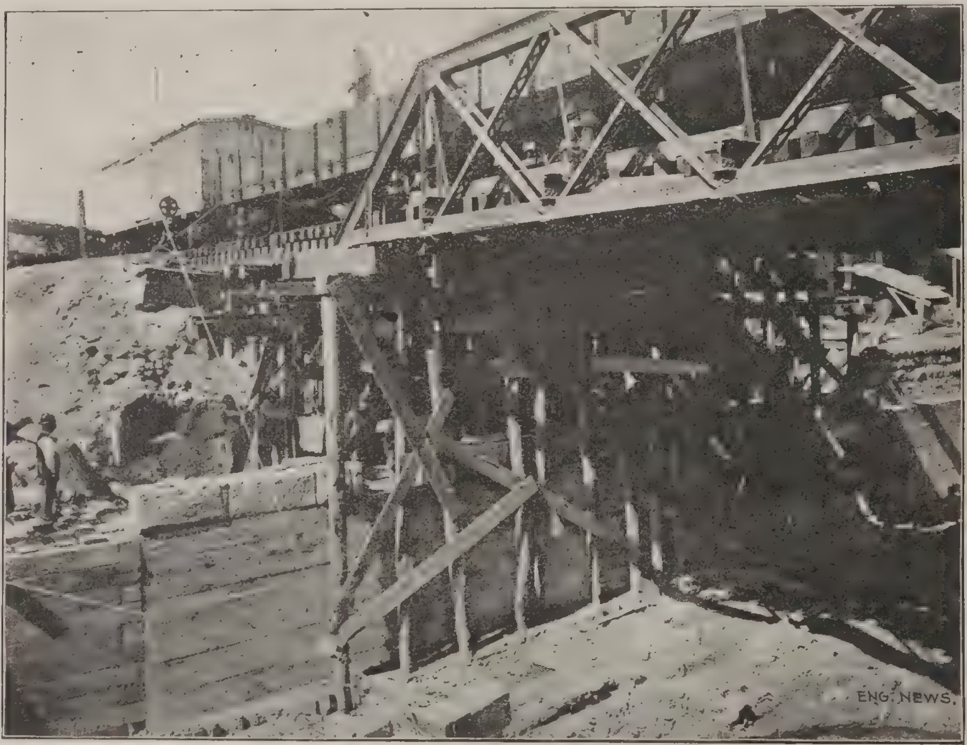
◆

A HAWAIIAN CABLE CONTRACT was signed, on July 2, between the executive council of the Hawaiian government and the Pacific Cable Co., of New York, granting the exclusive right to lay a submarine cable between the United States, Hawaii, Japan and China. The grant also includes the Ladrones and the Philippine Islands, subject to authorization by Congress. The proposed cable would start from San Francisco, and then proceed to the Hawaiian Islands, a distance of 2,097 miles, and thence to Japan and such other islands as shall be later designated. The total distance from San Francisco to Japan would be about 6,500 miles, or, with 16% of slack, about 7,500 miles of cable would be required. The estimated cost of cable and repair ship is $7,500,000. The official messages of the United States are to be transmitted free of cost forever. The officers of the Pacific Cable Co. are: James A. Schrmyser, president; Edmund L. Baylis, vice-president; and these gentlemen, with Rear Admiral John Irwin, J. Pierpont Morgan and J. Kennedy Tod, are the directors of the company.

CONCRETE ABUTMENTS FOR A RAILROAD BRIDGE AT BUFFALO, N. Y.

The rebuilding of the abutments of the three-track bridge of the Buffalo & Niagara Falls branch of the New York Central & Hudson River R. R. across the branch of the Erie Canal in Buffalo, N. Y., known as "Niagara Slip," was made necessary by the recent deepening of the Erie Canal, and the consequent removal of the glacial drift between the original abutments, which were built of stone masonry some thirty years ago, and were founded upon this drift. The rebuilding was done during March and April, 1898, by the Donnelly Contracting Co., of Buffalo, N. Y., and the arrangement of the work and plant present several features of interest. The underlying limestone formation occurred at an average of 10 ft. greater depth; its surface being very irregular and varying 5 ft. or more in the area of the abutments. This was scraped clean to receive the concrete forming the new structures.

The branch of the canal spanned by this bridge connects the Erie Canal proper with Buffalo harbor, and two cofferdams were, therefore, needed to shut off the water. This construction presented difficulties in that the adjacent formation in which the cofferdams must abut was of the most irregular and uncertain character, consisting of drift, lake beach gravel with embedded logs and drift wood, and "made ground" of varied materials. A deposit of 8 ft. of quicksand was encountered and required careful handling to avoid undermining a closely-adjacent brick round-house.



VIEW OF NORTH ABUTMENT OF N. Y. C. & H. R. R. R. THREE-TRACK BRIDGE AT BUFFALO, N. Y., IN PROCESS OF RECONSTRUCTION.

Walter Katte, M. Am. Soc. C. E., Chief Engineer.
Donnelly Contracting Co., Buffalo, N. Y., Contractors.

The bridge is in daily use by 250 or more regular and yard trains of the New York Central, Grand Trunk, Michigan Central, Toronto, Hamilton & Buffalo, and Canadian Pacific railways (three trains having often been seen on the bridge at once), and this service must be maintained without interruption. To permit this, the bridge was supported upon pile bents at either end, and a platform was built beneath the bridge on which were placed the materials, conveyor and mixer for the concrete.

The cofferdams were formed of crib-work 18 ft. wide and 22 ft. high, filled with clay. The crib-work, of 12 × 12-in. square timber, was so designed that, without extra labor in building it, the timber from the dry side of each dam could be taken out intact, and in condition to be used elsewhere. This was effected by using interior vertical posts with horizontal screw bolts, engaging the cross-ties and the face timbers, and with the nuts of the screw bolts exposed. No drift bolts were used in this face of the crib, and no gains were cut in the timbers to receive tie-heads, which came through full size, with the face timbers butting against the tie ends. Wakefield triple-lap and other forms of sheet piling were used to secure the ends of the dams and extend them, and no breaks occurred, though rises of the lake level of 6 ft. or more, caused by the winds down the lake, overflowed the dams twice.

After the area had been pumped dry, the old abutments were taken out, and the excavations for the new ones were made to the bed rock. Upon the irregular surface of this, the abutments were built of concrete for an average height of 18 ft. above rock (to low water line), and of rock-face, massive, stone masonry for 13 ft. above the concrete.

To construct the latter, an overhead track was built lengthwise of each abutment, upon which traveled a truck, from which was suspended a 10-ton Harrington hoist for the blocks of stone, which were thus carried to place and laid in the superstructure. These blocks were first lowered from cars on the bridge overhead by steam derricks, standing on the nearest cofferdam, and thus placed within reach of the truck-hoists.

The total quantities were 835 cu. yds. of concrete and 466 cu. yds. of masonry. The prices were $6.50 per cu. yd. for American Portland cement concrete, and $7.93 per cu. yd. for second-class masonry of rock-face sandstone and backing. The aggregate was $21,000 for the whole work, including building and removing of cofferdams, etc.

The concrete was formed of one part Atlas Portland cement, one part beach sand, and six parts of crushed corniferous limestone and flint, using the total product of the crusher when set at 2-in. opening; the finely-crushed limestone included in this product being equivalent to one part of sand in addition to that already named. These materials were mixed by four or more revolutions of a Ransome rotary mixer, which is so arranged with interior paddles that one revolution is equivalent to four turnings by hand shovels. The mixer was run by a 10-HP. engine, supplied with steam from one of the boilers operating one of the cofferdam pumps.

The crushed limestone and flint were run directly into dump cars at the contractor's crusher, and the cars were then hauled on to the bridge, where their contents were dumped through the floor of the bridge on to the mixer-platform beneath. The plank molds into which the concrete was filled and which confined it to the defined form and dimensions, were composed of smoothly-dressed plank placed with care to have the butts and joints tight to prevent leakage of any surplus water from the concrete. That portion of the forms which came between the pile bents supporting the bridge was braced against these piles, while the molds for the wing-walls were tied together—front and back—by iron tie-rods which were removed as the concrete filling came up to them. As the concrete was to be wholly submerged and out of sight, it was not considered that the face should be specially finished, and therefore the lines of the mold-plank show in the accompanying photograph.

The proportions of materials were here accurately measured in cubical barrows of 2 cu. ft. capacity each, and the concrete was made in batches of 16 cu. ft. every two hours, producing about 90 cu. yds. per day of ten hours. This was conveyed to place and thoroughly rammed in 10-in. layers with 6 × 8-in. wooden rammers. No concrete was made or placed at night, and each morning when work was resumed, a thin grout of clear Portland cement was spread over the top of the last-made concrete, just before placing the fresh concrete upon it. The actual weight of the resulting mass was found to be 159 lbs. per cu. ft. after the test-block of about 1 cu. ft. had been dried for two weeks in a warm room; this being 95% of the weight of the solid rock before crushing.

The work was under the direction of Mr. Walter Katte, M. Am. Soc. C. E., Chief Engineer of the N. Y. C. & H. R. R. R., with Mr. E. F. Van Hoesen, M. Am. Soc. C. E., Division Engineer; Mr. Wm. Pierson Judson, M. Am. Soc. C. E., was the engineer for the contractors.

The accompanying illustration shows the north abutment on April 14th, when the concrete base was completed, and the first course of sandstone superstructure was in progress. When completed and the cofferdams removed, the mean low water level stands about 1 ft. above the top of the concrete.

MARINE WOOD BORERS.

(With full-page plate.)

The destruction wrought by the teredo navalis upon marine constructions in wood is doubtless familiar in a general way to every engineer, but comparatively few are acquainted with the habits of this pest and with the methods by which he accomplishes his destructive work. It is also a fact not generally well known, perhaps, that the navalis is only one species of the teredo, and that the teredo is only one of several forms of wood borers known to naturalists and abounding in sufficient numbers to be a serious menace to marine works constructed of wood. In an interesting paper, by Prof. Charles H. Snow, of New York University, to be presented at the Detroit Convention of the American Society of Civil Engineers next week, the more destructive forms of these marine wood borers are described, with numerous illustrations of the animals themselves and their work. From these illustrations we have selected the engravings published on a full-page plate with this issue, and from the paper itself we abstract the following items of most interest in connection with them. We are indebted to the courtesy of the American Society of Civil Engineers for the use of the cuts.

The four forms of marine wood borers, which are the most numerous, and, consequently, about which the most is known, are: the teredo, the limnoria, the sphaeroma and the chelura. Of these the teredo is the most destructive, and therefore merits the most extended description:

The Teredo.

The teredo is a very ancient form of life, fossil remains having been found in both England and America. Among the ancients it has been mentioned in the writings of Pliny (23-79 A. D.). In modern times it was first observed and studied by the Dutch in 1730, when it threatened the woodwork of the Holland dykes. It has been since this latter date that most of our present knowledge of the teredo has been developed. Up to the present time seven species of teredo have been identified as existing in the United States, one of which is the navalis. This multiplicity of species needs to be remembered, since, owing to the comparatively greater familiarity of engineers with the navalis, the term "teredo navalis" is used indiscriminately by many engineers in speaking not only of the teredo but of all forms of marine wood-borers. The generic name is of course "teredo," which should be used always unless the specific form of teredo is known. These various species of teredo, however, are similar in their principal characteristics, which are shown by Fig. 1.

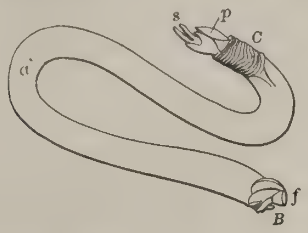


Fig. 1.—Sketch Diagram Showing Distinctive Features of the Teredo.

a, body; C, collar; p, pallets; s, syphons; B, boring shells; f, foot or sucker.

Notwithstanding its worm-like appearance, the animal is a true mollusk. Its principal parts are the body a, the collar C, the pallets p, the siphons s, the boring shells B, the foot or sucker f, and the lining shell. The last is a calcarious substance invariably deposited by the animal upon the newly cut surface of the tunnel which he excavates; and it forms an enameled lining through which he can glide backward and forward as he expands and contracts. The several members and their processes can be considered best separately.

The Body.—The body of the teredo in the young animal is so transparent that some of the interior organs, such as the heart and the ovary, may be observed through it. The heart consists of two auricles and a ventricle. The pulsations, which may be readily counted, are irregular, the rate being about four or five per minute. The blood is a transparent, colorless fluid. Many of the important organs, as the mouth, the palpi, the liver and the foot are inclosed in the boring shell at the further extremity of the animal. The gills are located for the most part at the outside of the shell, and are long and narrow, usually reddish brown in color, and perform the important office of sheltering the eggs and embryo. The nervous system is well developed, and consists of filaments and ganglions connecting the mouth, the branchiae, the foot, the collar and the syphons. The stomach is not distinguished by any peculiarity, but there is a well-developed intestine. The great length of the body is due to the elongation of the syphons or breathing tubes.

The Collar.—The collar extends entirely around the posterior portion of the animal, and fills the place between the body and the circumference of the tunnel. Water cannot pass through the orifice of the tunnel, save as it is controlled by the syphons. The collar contains several well-defined muscles, and these act upon the pallets, which are pulled down over the syphons in such a manner as to close the entrance to the tube when the extremities of the syphons are drawn into the burrow.

The Syphons.—The syphons are the two principal organs, and extend throughout the greater length of the body. One of these tubes conveys the oxygen, water and infusorial food to the vital processes of the animal; the other conveys the exhausted water, the excretions, the debris from the excavation and the eggs to the free water without. The outer structures of the syphons are united while they remain in the body, but signs of divergence are seen as they emerge from between the pallets. They continue united for a little and are then separated into two distinct tubes. These divergent extremities constitute the only part of the animal which can be seen from the outside, and are sometimes mistaken for the entire animal. The longer or incurrent extremity can be pushed out to a distance of 2 ins. or more, while the outcurrent throat remains at about half the distance. The teredo is able to expand or contract these extremities at will and when the conditions are favorable they are extended through the orifice to their full length, and remain stationary or wave slowly backward and forward. When the animal is alarmed the syphons are withdrawn into the tunnel. The siphons are erected by means of a current of blood sent into them from the vessels within. When the water is warm the animal is active and the siphons are extended out full length. They are withdrawn when the water becomes cold, and the teredo is entirely hidden. The extremities of the syphons must always be kept at the orifice of the wood. As the animal grows, the muscular collar and the pallets recede from the entrance, so as to permit the extremities of the syphon to remain there.

The Pallets.—The two shelly plates near the orifice are called pallets, and are connected with the muscles of the collar so that they relax when the syphon extremities pass out between the crescents or horns, which will be seen at the top of the shells, and contract when the syphons are withdrawn. The pallets are then folded over so as to serve as an operculum to protect the soft tubes from enemies.

The Boring Shell.—The boring shell, which is nearly as long as it is broad, presents an irregularly triangular appearance when observed from the side. It may be best seen in Fig. 2. The two halves close tightly at the hinge and at the side opposite the hinge; the open space at the top being toward the main bulk of the animal, and the opening toward the extremity of the tunnel permitting the emergence of the foot or sucker. The shells of young animals are larger in proportion than those of old animals, and when the animal is very young it is for a short time entirely enclosed in the shell.

The Foot.—The foot, which in form resembles a pestle, is a short, stout, muscular organ, broadly truncated or rounded at the end, and so arranged that it can exert a powerful suction upon anything to which it is attached. This cupping action assists the shell in excavating.

The Lining Shell.—This shell follows the tunnel until it finally terminates in a spherical cap. The adult animal occasionally shrinks, and a second cap or partition may be formed as he retreats, the space between the caps remaining unoccupied. The early portion of the tunnel, which was cut by the young animal and is later occupied by the syphon extremities, is below the normal diameter. The lining shell at this point sometimes divides itself into two tubes, each containing one of the syphons. It has been stated that the extremities of the syphons must be kept at the orifice of the wood. The collar and pallets recede as the animal grows larger, thus forming a considerable space between the pallets and the orifice of the tunnel, which is filled with little rings of shell, whose sharp edges serve to protect the entrance. The slender syphons emerging from the pallets pass readily through the spaces at the centers of the rings.

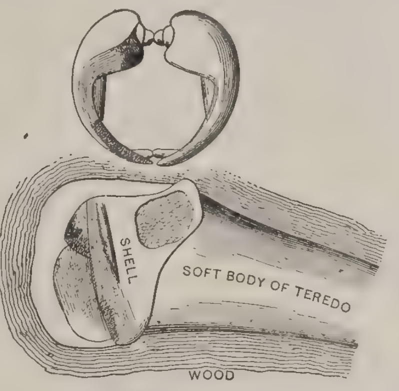

Fig. 2.—Enlarged Sketch of Head of Teredo, Showing Boring Shell.

The teredo can rarely advance for any time in a straight line, being forced to deviate therefrom so as to pass around obstacles, such as cracks, knots or the pre-existing tunnels of its companions. The tunnels may wind in and out and pass so close to one another as to occupy almost the entire content. This fact is well illustrated by Fig. 3.

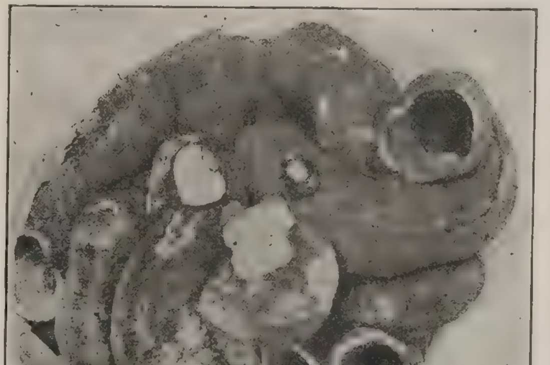

Fig. 3.—View Showing Proximity and Tortuous Nature of Tunnels Made by Teredo.

The thickness of the lining varies with the species. It is sometimes so thin and fragile that it becomes detached by the slightest shock, and is sometimes very thick. The lining presents a surface against which the soft body of the mollusk may press without injury, and also seals the interior of the cell so that the water supply may be better controlled by the syphons.

The teredo rarely crosses a seam or joint in the wood, probably because it fears for the integrity of the lining. Specimens exhibiting the attempt of the teredo to cross a seam show that the shell has been much strengthened at the junction point. When the teredo arrives at maturity, or whenever an insurmountable obstacle is encountered, it seals over the inner extremity of the lining. The growth of the animal, in length. is stopped in either case, and it is entirely surrounded by shell. There is a communication with the outer sea at the two syphon points only, and as the animal continues to live for some time under these conditions it is evident that its sustenance is derived from other sources than the wood.

Vital Processes.—The teredo resembles other bivalve mollusks in that it exists upon infusorial life. This food, together with the necessary amount of oxygen, is drawn in through the longer or incurrent syphon, and flows throughout the length of the animal until it reaches the mouth at the other extremity. The mouth, stomach and intestine are well developed and perform their usual offices. The oxygen is retained by the gills. The return current, beginning at the gills, removes the exhausted water, the excretions and the woody particles. These flow out through the animal and are ejected by the shorter or outcurrent syphon. The teredo does not devour wood; its form is such that dust and other debris have to pass through its body to the point of ejection. Where a teredo is watched for some time, small clouds of very fine dust may at length be observed puffed out from the orifice. The circulation through the syphons is continuous. The teredo may live for a short time out of water. This fact explains its ability to attack wood between high and low water. The specimens which enter wood where it is exposed between the tides do not seem to be greatly hindered in their work.

The Boring Apparatus.—While the animal is still very small, it settles upon the surface of the wood and almost immediately begins to clear away a place in which to burrow. A small pit is made by the edges of the valves of the shell, which come together on pivots shown in Fig. 2. The shells are controlled by powerful muscles acting so as to swing them backward and forward upon the pivots. Only a few of the teeth upon the shell are shown in Fig. 2, and these are exaggerated in size. When the posterior muscle contracts, the shell, with the teeth, is thrown outward and backward and rasps upon the surfaces of the wood. The process is assisted by the foot which emerges through the large blank space between the shells and performs a cupping action.

The Character of the Excavation.—The teredo is very small when it begins to attack the wood, and the hole by which entrance is made, which is the only perforation that appears upon the exterior, is very minute, as shown by Fig. 4. Fig. 5 shows the real interior condition of the same piece of wood. The animal develops very rapidly. The adult diameter is usually attained within 1 or 2 ins. of the surface, and the burrow increases in diameter regularly from the point of entrance to the maximum diameter. The animal grows principally in the direction of length, and therefore it atacks the wood so as to accommodate its quarters to this increase in length. The boring is first carried on across the grain, but ordinarily turns within a short distance and passes in the direction of the grain. This general direction is usually followed, but obstacles are so frequently encountered that the tunnels become exceedingly tortuous, and pass in every conceivable direction.

The teredo usually passes around knots, although quite competent to penetrate knots of oak and other hard woods. Adjoining tunnels are not encroached upon, because these tunnels are completely occupied by live teredos, and more ingenuity would be required to pass through one of them than to avoid it. When cracks exist in the centers of large timbers, they are approached from all sides, but the film is never willingly broken through. It prefers wood that is not surrounded by bark, because of the line of contact between the wood and the bark. When a piece of wood is thoroughly infested, the animals have to pass very close to one another, and the thin film of wood left between the adjacent tunnels is reinforced by the calcareous lining. More than 50% of the weight of the wood may be removed by the teredo, without being greatly evidenced upon the surface. Wood may appear to be quite sound and yet be so weakened that much of it can be crushed by the hand. Failure, therefore, frequently comes suddenly.

Fig. 6 is from a photograph of a log of Panama mahogany, which was cut in the uplands of the isthmus and floated through fresh water to the harbor of Colon, where it remained floating in salt water awaiting shipment. The log was overlooked for one season, and the work of the teredo is thought to have been accomplished in about nine months. The heavy, wet specimen was shipped with others, under the impression that it was sound, but it broke by its own weight after its arrival in New York.

The Size of the Teredo.—The size of the teredo depends upon the species, locality and age, and the absence of obstacles to excavation. Locality has much to do with development. Specimens grow more rapidly and attain larger size where the climate is warm. The teredo continues to grow until it reaches its maximum size, unless an obstacle is encountered. The species navalis may be assumed to average from about ¼ to ⅜-in. in diameter and from about 10 to 15 ins. in length, but specimens of the teredo frequently attain a much greater size. Prof. C. O. Siegerfoos, of Johns Hopkins University, writes that he has measured them up to 4 ft. in length and that the specimens thus measured had not arrived at their full limits. The minimum diameter and length of a boring may be taken as ¼-in. and 5 ins., respectively. The maximum length may be taken at 4 ft. After the teredo has penetrated the wood for a little distance, the diameter remains about constant. Diameters are measured in this portion of the burrow and not at the entrance.

The Range or Field of Work.—The teredo operates throughout a vertical field of considerable depth. This field begins at a point a little above low-water mark, and extends downward until the pressure becomes too great, or the soil at the bottom is encountered. The teredo seems to be able to exist for a little time without submergence, and is therefore able to live above the low-water mark, although exposed daily between the tides. The interior extremity of the tunnel may be higher up than the entrance. The upper limit of the excavated wood cannot be determined by an examination of the orifices at the surface. The lower limit is uncertain and is probably different for different species. It has been assumed by many that the lower limit could be set at about 14 ft. below low water, but recent information, thought to be reliable, indicates that piles have been affected at a depth of from 20 to 25 ft. below that level. The fact that the interior extremity of the burrow is often found below the mud line has given the impression that the field of the animal may extend below this limit, but the outside opening or entrance made by the teredo is never below the soil, although the boring may turn downward for the whole length of the animal. If sediment accumulates around the bottom of the wood so as to cover the syphons, the death of the teredo results.

It is reported that in some harbors the teredos attack at the surface, and in others at the mud line. These differences are partially due to differences in the constituents of the upper and lower layers of water. Where the fresh water of a river meets the heavy water of a sea, the teredo may be almost entirely confined to the lower stratum. The range or field of the teredo is important, because protective processes which could be confined to this field would be more economical than those in common use which are applied to the entire structure.

The Rapidity of the Work.—The rapidity of the work of the toredo depends upon conditions similar to those which govern its size. The evidence upon this subject is not always accompanied by a statement of the conditions under which the results were accomplished, such as the species of toredo, the character of the wood, the season, the climate and the depth of submergence, all of which are points as important as the geographical location of the work. The period in which the teredo accomplishes its work is variable. It may be six weeks or as many years, but rapid work is usually accomplished under the conditions which exist in warm climates. Impure water and cold weather retard its activity, while pure or warm water expedites the work. Maximum probabilities being more important than minimum possibilities, it is safe to assume that a 6-in. boring may be driven in six weeks, and hence, as the animal attacks all sides, a pile 1 ft. thick may be destroyed in that period.

Reproduction and Development.—Mollusks produce their young by means of eggs. Those of the teredo are spherical in shape and greenish yellow in color. The animal is exceedingly prolific; the eggs of a single specimen being probably numbered by the million. The eggs are first deposited in the gill cavity, and are almost at once fertilized. They are free-swimming at the end of three hours, have a well-developed shell before the end of the day, are very hardy, and all seem to be fertilized and to develop.

The embryo passes through several interesting stages before it assumes the character and form of the adult. It is first covered by fine hairs or cilia, which enable it to swim. These are soon lost, and the rudiments of a small bivalve shell appear, which is at first heart-shaped and very small, yet large enough to enclose the entire animal. The portion of the body which protrudes from the shell is fringed with cilia. These, again, constitute swimming organs, and the teredo swims actively until a piece of wood is encountered. The shell has now become rounder, and organs of sight and hearing have been developed. The appearance of these organs marks a climax in the life of the young animal, and it begins to elongate. The locomotive cilia disappear, the eyes are lost, and the mature form is gradually assumed. The life of the larvae is about four weeks, during all of which time they are free swimmers. If the animal has become attached to wood, however, its energies may be expended thereon. The life of a specimen which has not found any wood to attack has not been determined, but is probably quite short.

The extreme life limit of the teredo is unknown, but it is thought that under favorable conditions the animal may live for several years. In the vicinity of New York the processes of reproduction take place for the most part in May. They are not entirely confined to that month, however, but may extend throughout a greater part of the summer. Reproduction in tropical countries is probably extended throughout the entire year. The animal may develop to a very large size, and may possibly attain maturity in a single season.

The Effect of Climate, Temperature or Water.—The teredo navalis thrives best under the influence of heat, but, notwithstanding this fact, it can resist cold to a considerable degree. It is not active when subjected to low temperatures, yet it can endure them. Some species of the teredo have been reported as far north as Eastport, Me., and they exist abundantly under such conditions as obtain at Cape Cod. Destruction is not carried on as continuously or as rapidly in cold climates as in warmer ones, and for this reason maximum results are seen along the South Atlantic and Gulf States and on the Pacific Coast, where the conditions are more favorable, and where reproduction is continued during a longer period.

The purity of the water should be considered in connection with the work of the teredo. Some species inhabit pure sea water; some prefer brackish water, others abound in waters that are muddy, while others again live only in waters that are clear and pure.* The teredo is often present in certain waters, yet absent in the others nearly adjacent. This is usually due to some difference in the water. The xylotrya fimbriata seems to be able to survive the brackish, impure water of the inner New York Harbor, while other species could not live there, though they are present in the nearby outer ocean. The teredo is very active on the North Pacific Coast, yet is absent near the mouth of the Columbia, where the ocean is influenced by the outflow from the river.

The effect of the condition of the water upon the teredo is interesting. The opinion that the periods of unusual prevalence in Holland were in some way connected with a change in the quality of the water was expressed as early as 1733, and since that time has frequently been endorsed by Dutch engineers. Dr. von Baumhauer, Holland Commissioner to the Centennial Exposition, has called attention to the fact that but little rain fell in the years when the teredo was so unusually prevalent, hence the smaller volumes of river water were thought to have permitted larger proportions of salt to reach the coast. This theory is strengthened by the fact that analyses showed a variation in the proportion of salt during dry and rainy seasons.

The Distribution of the Teredo.—The teredo navalis has been identified as existing in the United States between Florida and Cape Cod, and in Europe, from Sweden to Sicily. The teredo norvegica has been found from Cape Cod northward to the coast of Maine. The teredo megotara has been found in floating pine wood at Newport, R. I., and in cedar buoys, etc., at New Bedford, Mass. It has been found south as far as the coast of South Carolina. The teredo dilatata occurs from Massachusetts Bay to South Carolina. The teredo thompsoni has been found at Cape Cod, Mass. The xylophaga dorsalis inhabits the waters of the North Atlantic. The xylotrya fimbriata is found along the Atlantic Coast from Long Island Sound to Florida. It also abounds in the waters of the North Pacific, and is one of the European forms. Different species of the teredo are notably present in such localities as the Bermudas, Jamaica, New Zealand and Australia. The teredo, as a rule, may be generally found in the tropics, and is hardly less numerous in many of the northern waters.

Woods Affected by the Teredo.—All varieties of wood commonly used in construction are subject to attack when exposed to the teredo. Immunity is occasionally claimed for some particular wood, but it will generally be found that the claims have been based upon local conditions and are not fully substantiated.

The following list of partially exempt woods has been compiled by Mr. T. A. Britton from authorities which are said to be reliable:† (Western Australia) jarrah, beefwood and tooart; (Bahama) stopperwood; (Brazil) sicupira, greenheart; (India) malabar teak, sisso, may-tobek; (South America) Santa Maria wood; (Tasmania) blue gum; and (West Indies) lignum vitae. It is not urged that these are entirely exempt, but that they have been exempt for long periods. Very few of them are widely known in construction. It is understood that at Southampton some greenheart piles have failed recently. It may be assumed that the conditions of impregnation or structure necessary to repel the teredo do not exist naturally in such woods as are commonly used in engineering works. It may also be assumed, so far as known at present, that partial or complete immunity, as applied to such woods as are in common use, is a question of locality rather than of variety of wood.

The Limnoria Lignorum.

This small crustacean has several names, as the limnoria terebrans, the gribble and the boring gribble. The limnoria has not been studied for so long a period as the teredo. It was first noticed by Robert Stevenson in 1810, and was examined by Dr. Leach, who one year later pronounced it a new species. It has been investigated since that time by numerous European writers, and, in the United States, it has been studied by Dr. Verrill, of Yale University, and Dr. Sidney I. Smith, of the United States Fish Commission.

The limnoria is gregarious and is found, if at all, in large quantities. It is much smaller than the teredo, but it exists in greater numbers. It has been traced from New York northward to the Bay of Fundy, and large numbers exist in the North Pacific Ocean. It is a very familiar and destructive form of life in Europe. If the destruction accomplished by the limnoria could be estimated it would be found to be surprisingly great.

Descriptive.—The limnoria, Fig. 7, is about as large as a grain of rice. The body is flat, round at each end, and consists of fourteen segments. The sides are nearly straight and are parallel to one another. To each of the seven segments which follow the head is attached a pair of short, stout legs, terminating in claws, the shape of which suggests the small claw of the lobster. The upper surface of the body is covered with small hairs to which more or less dirt usually adheres. The body is grayish in color, and sometimes resembles the color of the wet wood so much that it is difficult to distinguish it. The limnoria can swim, creep backward and forward, as well as jump backward by means of its tail. When touched, it rolls itself into a ball, and in this particular, as well as in general appearance, it resembles the common sow bug.

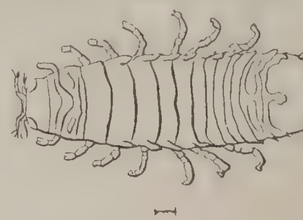

Fig. 7.—Sketch Showing General Appearance of Limnoria or Boring Gribble.

Vital Processes.—The limnoria differs from the teredo in that it is a vegetarian. The teredo is sustained by infusorial life, but the limnoria devours wood. Its tunnel affords both food and shelter.

Boring Apparatus.—The limnoria attacks the wood by means of its mandibles or claws. It prefers wet wood, and succeeds in making a very clean-cut excavation.

Character of the Excavation.—The work of the limnoria differs from that of the teredo in that it works upon the surface of the wood in such a manner as to be clearly seen. The limnoria is similar to the teredo in that its tunnel must communicate directly with the salt water; hence neither of these animals can live in the interior of thick woodwork, such as that of a caisson. The limnoria makes a small, round, parallel-sided tunnel through which it can pass freely back and forth from the sea. The diameter of the entrance of the tunnel is similar to the average diameter. The tunnels are quite short, and are placed very close together, as shown by Fig. 8. They are so numerous that the wood is rapidly reduced to a series of very thin partitions, which soon decay or are washed away by the waves, thus exposing a fresh surface which is at once attacked. Layer after layer is thus rapidly removed, so that the timber is destroyed in a very few years. The limnoria frequently works in conjunction with the teredo, attacking the exterior, while the teredo destroys the interior of the wood, and this combination effects a rapid destruction.

The limnoria attacks both the hard and soft parts of the wood. The hard annual layers have not been avoided in the specimens examined. The limnoria can penetrate knots, but frequently avoids them, so that these hard portions stand out in relief as the timbers waste away. Iron rust is said to cause a somewhat similar effect.

The Range or Field of Work.—The wide range observed between the several species of the teredo does not apply to the limnoria. Its work, as observed in the United States, is generally confined to a limited distance above and below the low-water mark. Where the variations of the tides are extensive, as in the vicinity of the Bay of Fundy, the range of the limnoria is correspondingly great. The United States Fish Commission states that it has been found, although rarely, as deep as 40 to 60 ft.

The Rapidity of the Work.—The limnoria does not work as rapidly as the teredo. The number of individual workers may be taken as a measure of the work they accomplish. The number of tunnels is more important than their depth. Limnoria are almost invariably found in large numbers and destroy a layer from ¼-in. to 1 in. in thickness in a year, the average yearly destruction being probably ½-in. Almost all wood used in marine locations is in the form of piles, which are necessarily exposed upon all sides. Their effective diameter may be reduced at the rate of 1 in. for each season, which result, while not equal to that accomplished by the teredo, is sufficient to cause a great loss.

The Effect of Climate, Temperature and Water.—The limnoria is found where the coldness of the climate prohibits the existence of the teredo. It requires pure sea water, and cannot exist in fresh or impure water, consequently it is not found at the mouths of rivers.

Distribution.—The animals are distributed along the American coast from Florida to Nova Scotia. They exist sparingly in Long Island Sound, but are quite numerous upon the coast of Massachusetts, and are very destructive in the Bay of Fundy. They are very active along the North Pacific coast, and are as much feared in the vicinity of Puget Sound and the Straits of Fuca. They exist also in abundance upon the coast of Great Britain and in other parts of Europe.

Woods Affected.—The limnoria seems willing to attack all varieties of wood commonly used by American constructors, but is said to prefer soft woods. It has been known to attack the gutta percha of submarine telegraph cables. It is said that teak wood is free from attack. Fig. 8 is a life-size photograph of part of a piece of wood from Port Townsend, Wash., showing the work of the limnoria.

---

*Percival Wright describes a kind of "ship worm" called Nausitora Dunlopei found in India, 70 miles from the sea, in perfectly fresh water.

†Treatise, "Dry Rot in Timber," p. 223.

Sphaeroma Destructor.

Attention has recently been called to this hitherto undescribed form of life. This animal is interesting in that it is active in comparatively fresh water. It resembles the limnoria, in that it attacks the wood from without, the interior of the wood being unaffected while the exterior is being destroyed. The work of these animals was first noticed upon some of the trestles of the Florida East Coast Railway in the vicinity of St. Johns River in Putnam County, Florida. Specimens of the wood were submitted to the Carbolineum Wood Preserving Co., of New York city, and were referred by them to the Smithsonian Institution at Washington, where they were studied by Miss Harriet Richardson. The animal somewhat resembles the limnoria in appearance, and is dark brown in color. It works between high and low-water marks. These are not tidal levels, but changes due to the wind assisted by the tides. The water appears to be quite fresh and the water hyacinth, which is not commonly found in salt water, flourishes in the vicinity. The distance to the ocean is about 100 miles.

The Chelura Terebrans.

This animal was first noticed at Trieste in 1839, and was next found in some piles in the harbor of Kingston. The chelura was not identified in America until 1875, when two small specimens were discovered by Prof. Sidney I. Smith at Wood's Holl, Mass. No others were observed until August, 1879, when Professor Verrill discovered a number of them in some piles at Provincetown, Mass. The chelura unquestionably belongs to the amphipods, and there is apparently but one species of the genus.

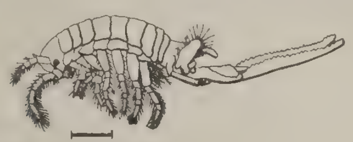

Fig. 9.—Sketch Showing General Appearance of Chelura Terebrans.

Descriptive.—The general appearance of the chelura, Fig. 9, resembles that of the ordinary shrimp, and for this reason is sometimes referred to as the wood shrimp. Its shape differs from that of the limnoria in a very striking degree. The two animals resemble one another only in size. The chelura is a very active little animal, and swims upon its back. It is a jumper, and can project itself to a considerable height when placed upon dry land, and in this respect resembles the sand hopper. The body is semi-translucent, and is thickly spotted or mottled with pink. The animal is distinguished by three pairs of caudal stylets, the last of which are nearly as long as the body. Those of the females or the young animals are not so long.

Vital Processes.—The chelura resembles the limnoria in that it is a vegetarian, and its burrow affords both residence and food. The fact that the chelura devours wood for sustenance is proved by the minutely divided ligneous matter found in the alimentary organs of dissected animals.

Boring Apparatus.—Professor Allman's original study of the chelura is in part yet regarded as authoritative. He states that the chelura attacks the wood and reduces it to minute fragments by means of a kind of file.

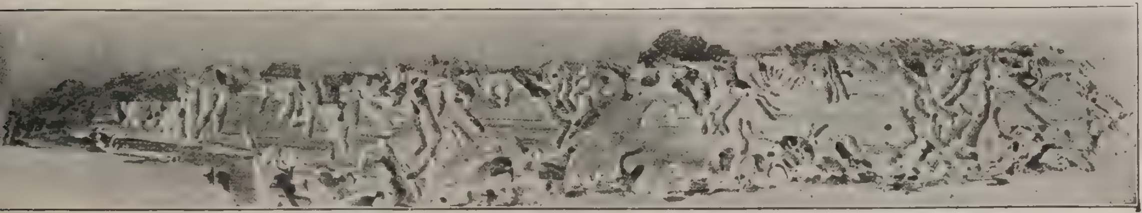

FIG. 10.—APPEARANCE OF TIMBER INFESTED BY CHELURA TEREBRANS.

The Character of the Excavation.—Great difficulty has been experienced in obtaining specimens of the work of the chelura, and those obtained are not sufficient to warrant many generalizations. In many particulars the work of the limnoria and of the chelura bear such a close resemblance, Fig. 10, as to lead to the suspicion that these animals are sometimes confused with one another. The excavations of the chelura are slightly larger than those of the limnoria, but are conducted in much the same manner, as the wood is attacked entirely from without. Numerous punctures are made, and then the weakened layers succumb to the action of the waves, the surface thus exposed being in turn attacked and the wood destroyed in the same manner. It is stated that the excavations of the chelura are more oblique in their direction than those of the limnoria, and this is certainly true of the specimens observed.

The chelura appears to prefer soft wood, and its attack is made as much as possible in the softer annual rings. The work of the chelura differs from that of the limnoria in that the latter attacks the wood at any available point, while the chelura, on the contrary, prefers the softer portions, and avoids the hard wood around knots. Perforations found in such localities may be assumed to be the work of the limnoria.

The Range of Field Work.—The question of range is unsettled. The specimens found at Provincetown were all taken from wood submerged from 8 to 12 ft. below low-water level.

The Distribution of the Chelura.—The chelura was sought many times along the American coast between New Jersey and Nova Scotia, but was not discovered until 1875. It is yet confined, so far as known, to the two original localities, Wood's Holl and Provincetown, both in Massachusetts, but it is more than possible that the animal has escaped observation, and that it is common on the North Atlantic coast. The unskilful eye would readily confound the chelura with the limnoria, although the two animals belong to distinct divisions of the crustaceans. It is quite possible that some of the damage hitherto ascribed to other animals has been accomplished by the chelura.

The chelura has been reported at many places on the coast of Europe, and is mentioned as existing from South Norway to the Adriatic. Attention has been called to the extent of its range. It is said to be an inhabitant of Australia. In Europe a very great amount of destruction is attributed to this species, and efforts have been made to substantiate these points, but have thus far been unsuccessful. It may be that some European results, attributed to this animal, are deserved by the limnoria, as it is probable that some of the work of the limnoria in America should be attributed to the chelura, and it is more than probable that the animals are frequently associated. Efforts to discover particular works affected exclusively by this form of life in Europe have not thus far met with success. The chelura has earned a most unenviable reputation in Europe, but it is not known in which places it exists as a specimen and in which as a pest.

* * *

A COMPLETE THEORY OF IMPULSE WATER WHEELS AND ITS APPLICATION TO THEIR DESIGN.

By R. T. Kingsford.*

The common theory of the impulse water wheel has been given so many times by different authors that the fact that it is only an approximation has been almost entirely lost sight of. It is well known that the speed of the bucket for maximum efficiency is not one-half of the velocity of the jet as the ordinary theory indicates, but from 85 to 95% of the half velocity.

The common theory is correct for the conditions assumed, i. e., a wheel of infinite radius and without friction; conditions that are impossible, and far enough from the facts to make the theory based on them of very little use to the designer and engineer. In a wheel of finite dimensions the bucket does not travel straight before the jet, but cuts through it at an angle of say 20° or 30°, and changes its direction relative to the jet by 70° or 80° before leaving it. It is usually stated also that for maximum hydraulic efficiency the direction of discharge relative to the bucket should be parallel and opposite to that of the jet, while in reality it should be tangential at all times, irrespective of the direction of the jet, for in no other way can the velocity of the bucket neutralize that of the discharging water on the bucket, and the resulting absolute discharge velocity become zero.

For the velocity of discharge to become zero, it is then necessary for the velocity of the water relative to the bucket at the point of discharge to be equal and opposite to the velocity of the discharge portion of the bucket. In practice the discharge velocity can never be quite zero, as the relative direction of discharge must depart from a tangent to the bucket's path, by a small angle of from 5° to 15° in order that the water may leave the wheel without being struck by and exerting back pressure on the succeeding bucket. Referring to Fig. 1, it is clear that the minimum value of this discharge angle, b, may be found from the equation

$$\tan b = \frac{n\ t}{2\ \pi\ R}. \qquad (1)$$

Where t = the combined thickness in feet, of water and bucket, at the point of discharge, as shown in the figure.

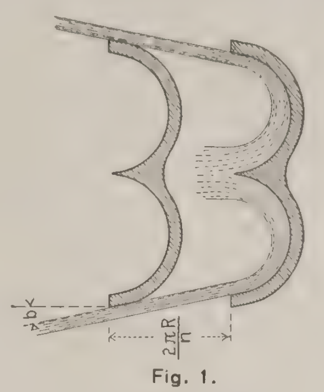

Fig. 1.

n = the number of buckets on the wheel.

R = radius in feet, to the average point of discharge from bucket.

To Find the Speed for Maximum Hydraulic Efficiency.

In Fig, 2, the nozzle T is shown, and four of the buckets or vanes, A F, N P, etc. The centre of the shaft is at M.

Let

H = Head of water available, before nozzle.
P = Pressure per sq. in. equivalent to head H.
V = Spouting velocity of jet in ft. per second = A C in figure.
v = Velocity of bucket for maximum hydraulic efficiency at average point of discharge, in ft. per second = F G in figure.
a = Angle of jet to the path of the average point of water entrance = $\cos^{-1}(p/r)$ = angle D A C in figure.
b = Angle between the direction of discharge relative to the bucket, and the path of bucket at average point of discharge = angle K F J in figure.
c = Average angle of water entrance on bucket = angle D A B in figure.
R = Radius of bucket at average point of discharge, in ft. = F M in figure.
r = Radius of bucket at average point of water entrance in ft. = A M in figure.
p = Perpendicular distance from center of wheel to center of jet in ft.
N_h = Revolutions per minute for maximum hydraulic efficiency.
S_h = Speed ratio for maximum hydraulic efficiency, i. e., ratio of circumferential velocity v of wheel to one-half the spouting velocity of the jet = 2 v/V.
C_f = Retardation or friction factor of water on buckets.
C_v = Retardation or friction factor of water in nozzle.

Referring to the figure, the absolute velocity of discharge F H will be a minimum, and, therefore, the hydraulic efficiency a maximum, when the tangential component F K of the relative discharge velocity F J is exactly neutralized by the velocity F G of the discharge portion of the bucket. The velocity of discharge F J relative to the bucket, is less than the velocity A B of entrance, because of friction between water and buckets, i. e., $F\ J = C_f \cdot A\ B$; also from the right angle triangle J K F, $F\ J = \frac{v}{\cos b}$, therefore,

$$D\ C = A\ B = \frac{v}{C_f \cos b}.$$

Since velocities of rotation vary as the radii, the velocity A D of the entrance portion of the bucket $= \frac{v\ r}{R}$.

Now, from the figure $A\ E = A\ D + D\ E$, or,

---

*120 Liberty St., N. Y. City.

$$V \cos a = \frac{v\,r}{R} + \frac{v}{C_f \cos b} \cos c;$$

which is

$$\frac{\cos c}{\cos b} = \frac{V}{v} C_f \cos a - \frac{r}{R} C_f. \tag{2}$$

From the figure, A C . sin a = D C . sin c, or $(A\,C)^2 \sin^2 a = (D\,C)^2 \sin^2 c$. Substituting A C = V, $D\,C = \frac{v}{C_f \cos b}$, $\sin^2 a = 1 - \cos^2 a$, and $\sin^2 c = 1 - \cos^2 c$, this becomes

$$\frac{\cos^2 c}{\cos^2 b} = \frac{1}{\cos^2 b} - \frac{V^2}{v^2} C_f^2 + \frac{V^2}{v^2} C_f^2 \cos^2 a. \tag{3}$$

Squaring (2) and equating its second member to the second member of (3),

$$\frac{r^2}{R^2} C_f^2 - 2 \frac{Vr}{vR} C_f^2 \cos a = \frac{1}{\cos^2 b} - \frac{V^2}{v^2} C_f^2. \tag{4}$$

To simplify this equation let

$$A = \frac{r}{R},\ B = A \cos a = \frac{p}{R}, \text{ and } C = \frac{1}{C_f \cos b},$$

then (4) becomes

$$\left(\frac{V}{v}\right)^2 - 2\,B \left(\frac{V}{v}\right) = C^2 - A^2,$$

and, solving for V/v, thus gives

$$\frac{V}{v} = B + \sqrt{B^2 + C^2 - A^2}. \tag{5}$$

and, therefore,

$$S_h = \frac{2}{B + \sqrt{B^2 + C^2 - A^2}}. \tag{6}$$

Knowing the speed ratio S_h, the speed of the wheel for maximum hydraulic efficiency N_h may be found from either of the equations,

$$N = \frac{15\,V\,S}{\pi R} = \frac{15\,S\,C_v \sqrt{2gh}}{\pi R} = \frac{183\,S\,C_v \sqrt{P}}{\pi R}$$

Where N = revolutions per minute, corresponding to any speed ratio, S.

To Find the Speed for Maximum Commercial Efficiency.

The effect of bearing friction is to drop the speed for maximum efficiency below that for maximum hydraulic efficiency. This is shown in Fig. 3. O A N C is a curve of HP. and speed of a wheel with frictionless bearings, and is therefore the hydraulic efficiency curve of the wheel. Bearing friction varies directly with the speed, and may therefore be represented by the straight line O J B. By subtracting the ordinates of O J B from those of the curve O A N C, the actual or commercial efficiency curve, O D K, is obtained, having its maximum, D, at a lower speed ratio.

The efficiency curve of a perfect wheel would be a parabola, and if a wheel has enough buckets, the actual curve does not depart from the parabolic form until the speed is beyond the point of maximum efficiency. In the figure, O A B C is a parabola corresponding to the curve O A N C, and this when combined with the line O J B, gives the parabola O D E.

It may be proven from the properties of the parabola, that the ratio of G F to O F is half the ratio of F J to F A, therefore,

$$C_b = \frac{2 - D}{2}. \tag{8}$$

Where, C_b = Ratio of speed for maximum commercial efficiency, to speed for maximum hydraulic efficiency = O G / O F in figure.

D = Ratio of power absorbed by friction at the speed for maximum hydraulic efficiency, to the maximum power that would be developed with frictionless bearings = F J / F A in figure.

Putting S_c = Speed ratio for maximum commercial efficiency = C_b, S_h, equation (6) gives

$$S_c = \frac{2 - D}{B + \sqrt{B^2 + C^2 - A^2}}. \tag{9}$$

Knowing S_c, the revolutions per minute may be found from equation (7).

To Find the Maximum Commercial Efficiency.

The losses in a mounted impulse wheel may be divided into nozzle, bucket, and bearing losses. Referring to Fig. 3, it may be proven from properties of the parabola that the miximum commercial efficiency G D, equals C_b^2 times the maximum hydraulic efficiency F A. Therefore,

$$E_c = C_b^2 E_h \tag{10}$$

In which E_c = Maximum commercial efficiency.

$E_h = C_v^2\ E$ = Maximum hydraulic efficiency.

E = Maximum efficiency of buckets.

The bucket losses may be further divided into losses due to clearance angle at discharge, friction of water or buckets, and irregular actions such as breaking up of the jet by impact, back pressure on buckets, etc. The irregular losses cannot be calculated, but are negligible when the entrance and discharge angles are correct, dividing edges sharp, and curvatures not abrupt. The proportion of power lost in the discharge (see Fig. 2)

$$= \frac{(F\,H)^2}{(A\,C)^2} = \frac{v^2 \tan^2 b}{V^2} \text{ or}$$

$$= \frac{S_h^2 \tan^2 b}{4} \tag{11}$$

The effect of friction between water and bucket is to reduce the velocity of the water, and produce a polygon of forces on the surface of the bucket, the resultant of which is practically perpendicular to the plane of rotation, and, therefore, lost.

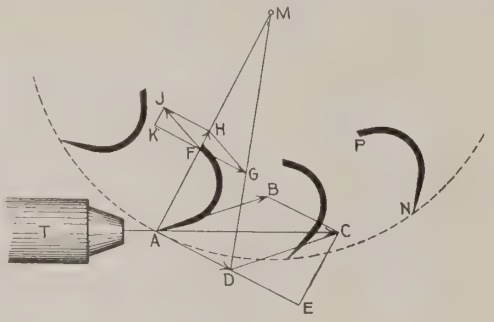

Fig. 2.

The proportion of bucket friction loss

$$= \frac{(A\,B)^2 - (F\,J)^2}{V^2} \text{ (Fig. 2.)}$$

Substituting $A\,B = \frac{F\,J}{C_f}$, and $F\,J = \frac{V\,S_h}{2 \cos b}$, this becomes

$$\frac{S_h^2 (1 - C_f^2)}{4\,C_f^2 \cos^2 b} \tag{12}$$

therefore from (11) and (12) the maximum efficiency of the bucket is

$$E = 1 - \frac{S_h^2 \tan^2 b}{4} - \frac{S_h^2 (1 - C_f^2)}{4\,C_f^2 \cos^2 b} \tag{13}$$

the second term being the loss at discharge and the third that due to bucket friction. The maximum commercial efficiency may now be found from (10) and (13), thus:

$$E_c = C_b^2\ C_v^2\ E \tag{14}$$

To Find the Proper Number of Buckets.

The number of buckets has much to do with the efficiency and regulation of the wheel. If too many, the losses due to the breaking up of the jet, clearance angle, and bucket water friction, will be much increased; and if too few, part of the water will pass through between the buckets without imparting its energy to the wheel. The effect of the latter on the efficiency is shown in Fig. 3 by the falling away of the efficiency curves O A N C and O D K at high speeds.

In Fig. 4, A B is the bottom of the jet, and A and C two adjacent bucket tips. A particle of water having just passed under bucket A, must overtake bucket C, before it reaches B; i. e., for the minimum number of buckets, the time of the jet from A to B equals the time of the bucket from C to B.

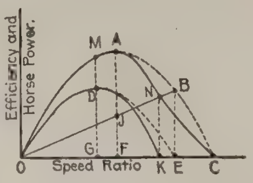

Fig. 3.

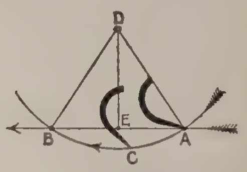

Fig. 4.

Let n_o = Minimum number of buckets allowable.

d = Diameter of jet, in feet.

e = Half the angle subtended by the bottom of the jet = angle E D A in the figure $= \cos^{-1} \frac{2\,p + d}{2\,r_1}$

p = Perpendicular distance in feet from centre of wheel to centre of jet.

r_1 = Radius of bucket in feet at tip, or initial point of water entrance on bucket = D A in figure.

S_b = Speed ratio at which water commences to pass through between buckets. It must not be taken less than S_c.

The time of jet from A to B is

$$\frac{2\,r_1 \sin e}{V} \tag{15}$$

The time of bucket from C to B is

$$\frac{2\,R}{V\,r_1\,S_b} \cdot C\,B \tag{16}$$

and, from the figure, C B = A C B — A C

$$= 2\,\pi\,r_1 \left(\frac{e}{180} - \frac{1}{n_o}\right)$$

Substituting value of C B, equating (15) and (16) and solving for n_o,

$$n_o = \frac{180\,\pi\,R}{\pi\,R\,e - 90\,S_b\,r_1 \sin e} \tag{17}$$

If a wheel is to be used without a governor, S_b should be taken as small as possible, so that the rapid falling off of efficiency at speeds higher than that for maximum efficiency, will tend to prevent racing at light loads.

To Find the Entrance Angle of the Bucket.

In order to prevent loss by the generation of heat, formation of eddies, backwater, etc., the bucket surface at entrance should be parallel to the course of the jet relative to the wheel.

Let c_1 = Angle between entering or initial edge of bucket, and an arc of radius r_1, = angle D A B in Fig. 2.

$a_1 = \cos^{-1} p/r_1$ = angle between center line of jet, and an arc of radius r_1, = angle D A C in Fig. 2.

From the figure, $D\,E \cdot \tan c_1 = A\,C \cdot \sin a_1$, or,

$$\tan c_1 = \frac{A\,C \cdot \sin a_1}{A\,E - A\,D},$$

and substituting $A\,E = V \cos a_1$, and $A\,D = \frac{V\,S_c\,r_1}{2\,R}$, this gives

$$\cot c_1 = \cot a_1 - \frac{S_c\,r_1}{2\,R \sin a_1} \tag{18}$$

Calculations of a Wheel of 32-in. Nominal Diameter.

The following calculations will serve to show the application of the preceding formulae:

The wheel in question is of the tangential type, discharging on the sides; the principal dimensions being, diameter outside of buckets, 35 ins.; radial length of buckets, 4 ins.; diameter of jet, 2 ins., radius to center line of jet, 15¼ ins. These dimensions, in the notation used, give:

$$r_1 = \frac{35}{2 \times 12} = 1.46;$$

$$d = \frac{2}{12} = 0.167;$$

$$p = \frac{15.25}{12} = 1.27.$$

The average radius of entrance will necessarily be between p and r_1, and may be taken as equal to ¾ p + ¼ r_1; i. e.,

$$r = 0.95 + 0.36 = 1.31.$$

The average radius of discharge will be slightly less than p. With type of wheel it may be taken equal to 1.5 p — 0.5 r, or

$$R = 1.9 - 0.65 = 1.25.$$

The value of S_b should be taken to suit the conditions under which the wheel is to run, as previously explained. Ordinarily take

$$S_b = 1.1.$$

Half the angle subtended by the bottom of the jet equals

$$e = \cos^{-1} \frac{2\,p + d}{2\,r_1}, \text{ or,}$$

$$e = \cos^{-1} (0.93) = 21° \, 30'.$$

To find the proper number of buckets use equation (17),

$$n_0 = \frac{180 \times 3.1416 \times 1.25}{3.1416 \times 1.25 \times 21.5 - 90 \times 1.1 \times 1.46 \times 0.366} = 24.$$

The combined thickness, t, of water and bucket at discharge equals $\dfrac{\text{Area of jet}}{2 \times \text{Radial length of bucket}}$ + thickness of bucket and an allowance for irregularity. In this case, make

$$t = ¾\text{-in.} = 0.0625.$$

To find the minimum clearance angle, b. use equation (1).

$$b = \tan^{-1} \frac{24 \times .0625}{2 \times 3.1416 \times 1.25} = 11°.$$

The actual angle of discharge will probably be about 16°. The friction factor of the water on the bucket C_f must be found experimentally. It increases with the extent and roughness of the surface. Assume,

$$C_f = 0.94.$$

To find the speed ratio S_h, for maximum hydraulic efficiency, use equation (6). In this equation,

$$A = \frac{r}{R} = 1.05,\ B = \frac{p}{R} = 1.02,\ C = \frac{1}{C_f \cos b} = 1.11$$

$$S_h = \frac{2}{1.02 + \sqrt{1.04 + 1.23 - 1.1}} = 0.954$$

The proportion of bearing friction, air resistance, etc., must be estimated. Assume D = 0.03. The coefficient C_b may now be found from equxation (8),

$$C_b = \frac{2 - 0.03}{2} = 0.985.$$

The speed ratio, S_c, for maximum commercial efficiency, may be found from equation (9),

$$S_c = C_b \; S_h = 0.94.$$

The friction factor C_v, of the water in the nozzle, increases with the taper angle, being almost unity for a thin flat plate, and for a reamed taper of not less than 25°, it is seldom less than 0.96 or 0.97. Assume

$$C_v = 0.97.$$

The correct speed in revolutions per minute may now be found for any head or pressure from equation (7),

$$N = \frac{183 \times 0.94 \times 0.97}{3.1416 \times 1.25} \sqrt{P} = 42.5 \sqrt{P},$$

The efficiency, E, of the bucket may now be found from equation (13),

$$E = 1 - 0.019 - 0.034 = 0.947.$$

Knowing E, C_b, and C_v, the maximum commercial efficiency may be found from (14),

$$E_c = 0.97 \times 0.94 \times 0.947 = 86\%.$$

To obtain this efficiency, the wheel must be run at the correct speed: i. e., $N = 42.5 \sqrt{P}$, as found above, and the entrance angle of the bucket must be correct.

To get this angle, use equation (18), in which

$$a_1 = \cos^{-1} p/r_1 = 29° \, 30'.$$

Then the correct angle for the entering edge of the bucket is, from (18),

$$c_1 = \cos^{-1} (1.78 - 1.12) = 56° \, 30'.$$

With some wheels the bucket is of such a form that the loss at discharge would be much increased if the angle were made as large as formula (18) indicates, and a compromise has to be made. This is, however, a source of considerable loss and should be avoided by proper designing.

◆

ATMOSPHERIC RESISTANCE TO THE MOTION OF RAILWAY TRAINS.

In a paper with the above title by Prof. W. F. M. Goss, published in the "Proceedings of the Western Railway Club" for April, 1898, there is described a series of experiments on wind resistance of small models of railway cars, from which the author deduces a set of formulas for the air resistance of actual trains of different number of cars at various speeds. The models used were 1-32 the size of an assumed standard box car, or 12 1-16 ins. long, 3⅛ ins. wide and 4½ ins. high. They were placed inside of a smooth air-tight wooden conduit with glass sides, 20 ins. square, 60 ft. long, through which air was blown by means of a fan blower, the velocity of the air current being ascertained by Pitot tube gages. The pressure exerted by the wind in the direction of the axis of the conduit was measured by a very sensitive dynamometer attached to each car. The condition of the cars being at rest and the air in motion was taken as equivalent, so far as the pressure tending to move the cars was concerned, to the natural condition of cars in motion through still air. Numerous observations were made with the number of cars varying from 1 to 25 and with velocities of air from 25 to 105 miles per hour. The actual pressures on the model cars, as registered by the dynamometers, were compared with the theoretical pressures due to the velocity calculated from the formula $P = .0025\ V^2$, in which P = pressure per square foot and V = velocity in miles per hour.*

It was found that when one model only was used the ratio of the force tending to displace the model to the pressure due the velocity was respectively 0.61, 0.54, 0.48, 0.47 and 0.49 for velocities of 25, 41, 73, 88 and 102 miles per hour. For the speeds higher than 25 miles per hour the average ratio approximates 50%. When two models, placed end to end, were used the pressure on the first was about 40% and that on the second about 13%, a total on both of about 53% of the theoretical pressure acting on an area equal to the cross section of a model. For three models the pressures were respectively about 0.40, 0.05 and 0.13 of the theoretical, a total of 58%. For five models the pressures were about 0.39, 0.03, 0.04, 0.04, 0.11, a total of 61%. For ten models the pressure on the first was about 0.39, on the second to the ninth inclusive about 0.039 each, or one-tenth that on the first, and on the tenth about 0.1, making a total of 80% of the theoretical pressure on the cross section of one model. With 25 models the pressures were about the same on the first, last and intermediate models respectively as with ten models, the sum of the pressures for the 25 models being about 1.4 times the theoretical end pressure on a single model. In all cases of trains of more than ten models, however, the pressure on the second model of the train is somewhat less than that upon the third or any other succeeding model except the last.

The relation between the force and the velocity upon the several models of a train may be expressed by the following equations:

For a single model, $A = 0.000116\ V^2$.
For the first model of a train, $A = 0.000097\ V^2$.
For the last model of a train, $A = 0.000025\ V^2$.
For the second model of a train, $A = 0.000008\ V^2$.
For any intermediate model, $A = 0.000010\ V^2$.

In which A = the force in pounds acting on the model in the direction of its length, and V = the velocity of the air current in miles per hour. These equations apply only to models of the particular dimensions used. Equations of a more general character are obtained by reducing the forces acting upon each model to equivalent forces per square foot of area of cross section, as follows:

For the Pitot gage, $P = 0.0025\ V^2$.
For the model alone, $P = 0.0012\ V^2$.
For the first model of a train, $P = 0.001\ V^2$.
For the last model of a train, $P = 0.00026\ V^2$.
For the second model of a train, $P = 0.00008\ V^2$.
For any intermediate model between the second and the last, $P = 0.0001\ V^2$.

The models being 1-32 the size of a 33-ft. box car, the area of surface of an actual car is 32^2 = 1,024 times the surface of a model. The coefficients of V^2 in the above formulae being multiplied by 1,024 the resulting values of P will then represent the atmospheric resistance to the passage of an actual car at the speed of V. The atmospheric resistance of trains of such cars is the sum of the resistances of the several cars, and it may be expressed by the following formula, which is developed from those already given:

$$A = (0.105 + 0.010\ N)\ V^2,$$

in which A = the resistance in pounds, N the number of cars in the train, and V the speed in miles per hour. In a train of cars headed by a locomotive and tender, the locomotive should be regarded as the first car and the tender the second. A passenger car may be considered as equivalent to two freight cars. Taking the freight car as 33 ft. in length, a formula may be constructed in which the length of the train in feet, instead of the number of cars, is a factor.

Prof. Goss concludes his paper by summarizing his several formulae in the convenient forms given below. He says they apply to trains and parts of trains having an area of cross-section equal to that which is common in American practice, with possible errors of from 15 to 20% in individual cases. In the following equations A is the tractive force in pounds necessary to overcome the resistance of the atmosphere, and V the velocity in miles per hour:

a. For a locomotive and tender running alone: $A = 0.13\ V^2$.

b. For a locomotive and tender running at the head of a train: $A = 0.11\ V^2$.

c. For the last car of a train of freight cars: $A = 0.026\ V^2$.

d. For the last car of a train of passenger cars: $A = 0.036\ V^2$.

e. For each intermediate freight car in a train of 33-ft. cars: $A = 0.01\ V^2$.

f. For each intermediate passenger car in a train of 66-ft. cars: $A = 0.02\ V^2$.

g. For a train consisting of locomotive, tender and freight cars: $A = (0.13 + 0.01\ C)\ V^2$, where C is the number of cars in the train.

h. For a train consisting of locomotive, tender and passenger cars: $A = (0.13 + 0.02\ C)\ V^2$.

i. For a train of freight cars following a locomotive, but not including either locomotive or tender, $A = (0.016 + 0.01\ C)\ V^2$.

j. For a train of passenger cars following a locomotive, but not including either locomotive or tender, $A = (0.016 + 0.02\ C)\ V^2$.

k. For a locomotive and any train, either freight or passenger: $A = 0.0003\ (L + 347)\ V^2$, where L is the length of the train in feet.

l. For a train of cars, either passenger or freight, following a locomotive, but not including either locomotive or tender: $A = 0.0003\ (L + 53)\ V^2$, where L is the combined length of the cars composing the train.

---

*[The theoretical pressure due the velocity is $0.005\ V^2$ instead of $0.0025\ V^2$. The theoretical pressure produced by a jet of any fluid on a plane surface at right angles to the jet is equivalent to twice the head which would cause the velocity, or $\frac{2\,v^2}{2\,g}$, v being the velocity in feet per second (see Church's Mechanics, pp. 761, 803). If A = area of the plane in sq. ft., w = weight of 1 cu. ft. of air = 0.0761 at 62° F. and atmospheric pressure, and F = total pressure on the plane. $F = A\,w\,\frac{v^2}{g}$. If A = 1, w = 0.0761, and g = 32.2, $F = 0.00236\ v^2$. If v is taken in miles per hour, $v = 22 \div 15$, $v^2 = 2.15$, and $F = 0.00507\ V^2$. This correction will cause all the figures given by Prof. Goss to express the relation of observed to theoretical pressures to be divided by 2, but it makes no change in his formulas for resistance, which are based on experiment and not on theory.—Ed. Eng. News.]

THE BLUNT DIVIDING ENGINE, built by E. & G. W. Blunt, of New York, in 1851-58, has been secured, along with the business of Mr. F. Eskel, by Kolesch & Co., manufacturers of drawing instruments, of 155 Fulton St., New York. This engine, which was one of the first built in this country, and is still one of the best in use, has a circle 35 ins. diameter, with the circumference divided into 2,160 parts, with six divisions to one degree. The engine was considered so important that an illustrated description of it was published in book-form, in 1858, detailing the methods employed in dividing the circle, cutting the circumferential teeth and in applying it to the division of the circles of surveying and astronomical instruments. The book contains a certificate by the late J. E. Hilgard, of the U. S. Coast Survey, attesting the accuracy of the work.

SUBSCRIPTION RATES: United States, Canada and Mexico, One Year, $5.00; *6 months,* $2.50; *2 months,* $1.00. *To all other countries in the Postal Union: Regular Edition, One Year,* $7.60 (31 *shillings*); *Thin Paper Edition, One Year,* $6.31 (26 *shillings*). *SINGLE COPIES of any number in current year,* 15 *cents.*

Mailing addresses may be changed at will by sending both old and new address. The number on the address label of each paper indicates when subscription expires, the last figure indicating the year and the one or two preceding figures the week of that year; for instance, the number 328 *means that subscription is paid to the* 32*d week (that is the issue of Aug.* 11) *of the year* 1898; *the change of these figures is the only receipt sent, unless by special request.*

ADVERTISING RATES: 20 *cents per line. Want notices, special rates, see page* 18. *Rates for standing advertisements sent on request. Changes in standing advertisements must be received by Monday afternoon; new advertisements, Tuesday afternoon; transient advertisements by Wednesday noon.*

We published in our issue of July 7 a report made by Mr. Henry B. Seaman, M. Am. Soc. C. E., on the condition of the various paints applied to the 155th St. viaduct over the tracks of the Manhattan Elevated Ry., in New York city. We accepted and published the report on the strength of Mr. Seaman's reputation, without taking measures to verify its accuracy; but as some severe criticisms of this report have been since presented to us, two members of the editorial staff of this journal visited this structure on July 16 and carefully examined it. As a result of this examination we are obliged to advise our readers that no conclusion whatever as to the relative merits of the various paints under test should be based on Mr. Seaman's report, and we regret having given publicity to it.

To explain more in detail, Mr. Seaman in his report said:

> In making the examination, a careful general scrutiny was given to each girder from the platform below, and each was given a percentage mark, denoting the amount of surface free from rust. These percentages were then carefully compared and reviewed so that they might correctly represent the comparative condition of each girder. When these tests were completed, a thorough inspection was made by climbing through the structure, and the character of rust was denoted for each girder.

In the table accompanying Mr. Seaman's report, the percentages of the surface of each girder free from rust varied from 99% to 25%, and some of these percentages differed by as little as 2% from each other. The editors of this journal who have examined the structure agree in stating that no such accurate estimate as these percentages would indicate is possible by examining these girders from the platforms; and in fact no reliable estimate is possible at all with the girders in their present condition. They have examined the structure from the platforms, and also climbed through it, as did Mr. Seaman. They find practically the entire steel-work covered with a coating of ash, dust, soot, etc., so that any accurate comparison of the conditions of the different paints is impossible. It must be understood that nowhere on the whole viaduct are there patches of deep red rust, such as are found on an iron structure after considerable exposure to the weather, and which stand out plainly against any dark paint. Such rust as is to be found on this structure is for the most part in the form of fine pin points, except where leakage from the floor overhead has spread rusty water on the iron and has discolored it or caused local rusting. To determine accurately the percentage of surface free from rust under these conditions and especially from the platforms 17 ft. below as Mr. Seaman claims to have done, is about as easy as counting the bees in a swarm. We do not mean to say that no differences in the condition of the various paints are discernible. On the contrary, Girders Nos. 3 and 8 are, as Mr. Seaman indicates, in much worse condition than any of the others; at the same time his percentages, 25% and 30%, as the surface of these girders free from rust, would in our opinion be more accurate if stated as 25% covered with rust. We allude to this merely to show that any estimate of the percentage of surface free from rust on the various girders of this viaduct is a matter of rough guess-work under present conditions, and probably no two experts could be found who would guess alike.

The test of paints in progress at this place promises to furnish some interesting and valuable data sometime; but we believe it is too soon yet to make any comparison of the conditions of these various paints that will be worthy of general acceptance by the profession. At least a dozen of these girders show trifling if any difference in their condition, and this is really to be expected, considering that this paint has not been on a year yet and it was applied to an iron surface as clean as the sand-blast could make it.

After the paint has been in service for two years or so, it would be an excellent idea for the committee of the American Society of Civil Engineers, which has in charge the subject of paints for metal work, to make a thorough examination of and report upon the condition of the various paints on this structure. Such a report would carry weight with the profession that could not attach to a report made by any city official or any single engineer, however expert.

◆

Judging from a communication in the Cleveland "Plaindealer," of June 30, one C. C. Merrill, Manager of the Mexican Clay Co., of the City of Mexico, has either been very unfortunate in the selection of his acquaintances; or, he should be at once employed in writing war despatches for Governor General Blanco. This party is making sewer-pipe for the Mexican government under a valuable concession, and, doubtless, for purposes of his own, indulges in fulsome and uncalled-for praise of the strict honesty of the Mexican officials with whom he has to deal. There is no particular harm in this; but he then goes on to draw comparisons between the Mexican and the American engineer, and says that in selling sewer-pipe in the United States, "I never found an American engineer that I could not buy, except he had been bought up by the man ahead of me." As to this statement, Mr. Merrill has either had an exceedingly limited experience as a selling agent; or, what is much more probable, he simply lies. There is no doubt from his own confession but that Mr. Merrill is venal enough, for in his statement he calmly acknowledges offering to a Spanish Chief Engineer terms of "mutual benefit." The mistake he makes is in measuring others by his individual standard.

◆

In the description of the process of liquefying air in use by Mr. Chas. E. Tripler, of New York City, in our issue of April 14, we described the method and apparatus by which a portion of the highly compressed air is made to furnish a refrigerating effect which causes liquefaction of another portion of the air.

An English inventor, Dr. W. Hampson, now claims to be the original inventor of this process of "Self-Intensive Refrigeration," as he terms it. In a paper printed in the "Journal of the Society of Chemical Industry, May 31, 1898, Dr. Hampson explains in detail his method of liquefying air, and gives his reasons for believing himself to be the original inventor of this process of liquefaction of air and other gases.

So far as we have been able to find, neither Dr. Hampson nor Mr. Tripler have taken out American patents on their inventions yet. Mr. Tripler has an English patent (No. 4210 of 1893), which Dr. Hampson alleges is actually a heating apparatus instead of a refrigerating one, and he further claims that Tripler's successful production of liquid air has all been done since the publication of the Hampson system and apparatus in 1895.

Those interested in the subject of liquid air will do well to secure a copy of Dr. Hampson's pamphlet, which is printed by Eyre & Spottiswoode, the well-known London publishers. We presume that the United States patent office will have to sift the question between the two claimants in an interference case.

◆

The vexed question of the improvement of the Chicago River in order to make it navigable for the large steamers now coming into use was brought up for discussion at the meeting of the Western Society of Engineers on June 1. At this meeting a paper was presented by Mr. G. A. M. Liljencranz, U. S. Assistant Engineer, describing the existing obstructions to the navigation of large vessels. A number of plans of awkward locations on the river were exhibited, on which the outline of a large steamer had been plotted, showing graphically the difficulty, and in some cases the impossibility, of such a ship getting through. The general situation and the relation of the Chicago River to the commercial interests of the city have already been fully presented in our columns, and it is only necessary here to state briefly the conditions. The narrow and tortuous channel, which is obstructed by numerous docks, bridges, bridge piers, the roofs of three tunnels, and numerous bends and sharp turns, passes through a business and industrial district, and is traversed by a very large tonnage of shipping in the trade with the freight wharves, grain elevators, coal and lumber yards, etc., which have been established along the stream. At present the river is practically a navigable sewer, the water being black and offensive and the bottom being a soft foul mud which is kept stirred up by the steamers. It is expected that this condition at least will be improved when the drainage canal is completed, but the filthiness and dilapidated condition of the surroundings will remain unless some radical steps are taken for the general improvement of the river. It is not generally known that there is an existing ordinance (passed in 1869), establishing certain dock lines, but this is absolutely a dead letter and docks are built far beyond the prescribed limits, without regard to the requirements of navigation. The drainage board will increase the waterway at some points, in order to secure the necessary amount of flow to the canal, but this will be done by means of covered conduits and will not improve the navigation. For the latter purpose, the U. S. government has undertaken to cut off corners and widen the channel at certain points, but this work will be of limited extent, and is but a temporary expedient. It will remain for the city to undertake the more extensive work of lowering the tunnels, and replacing the center-pier drawbridges with bascule bridges which will neither obstruct the channel nor interfere with the wharfage adjacent to the bridges. With this might and should come a general rectification of the channel and an improvement of the river front.

It certainly seems evident that the city should delay no longer, but at once take the matter in hand, as there is urgent necessity for the adoption of some definite plan for the improvement of the long-neglected river on a bold scale, and not by mere petty improvements which practically leave the general problem untouched. When once such a plan is adopted, the work of carrying it into effect can be done gradually as means will permit. The size of steamers employed in the lake traffic has shown a marked increase within recent years, and the government is now establishing a 21-ft. channel through the lakes between Duluth, Chicago and Buffalo. In recent reports, Major W. L. Marshall, U. S. Engineers, has shown that many of the large vessels whose length and beam enable them to pass through the Chicago River, cannot be given a full load on account of the limitation of draft by the tunnels, and cases are not infrequent where loaded steamers ground in the shallow water over these tunnels.

◆

The return to Spain of the 25,000 prisoners of war lately taken at Santiago seems to be not only the

MARINE WOOD BORERS.

most economical method of dealing with the problem, but also an eminently wise educational step. These returning prisoners have met the Americans in battle; they have practically witnessed the destruction of Spain's best fleet; they know how our soldiers can fight and our sailors can shoot; and every man of them will be a missionary in Spain, helping vastly to dispel the dense ignorance concerning the United States, which is now one of the greatest obstacles to the restoration of peace. On the other hand, it is an economical plan, because the per capita cost of transferring these prisoners to a Spanish port is small compared with the expense of bringing them from Santiago to the United States, and then feeding and guarding them for an uncertain length of time. There is besides the added risk of importing disease should the prisoners be brought to this country.

◆

In our issue of July 7, in referring to the four Spanish cruisers sunk at the battle of Santiago, we stated that their armor was Harveyized nickel steel. A correspondent asks our authority for this, and we find on more careful investigation that the "Cristobal Colon" had a belt of 6-in. Harveyized armor, whether nickel steel or not we cannot say. The other three vessels had 12-in. side armor, of what material we are not informed, but, judging by the date the vessels were built, it probably was not nickel steel or Harveyized.

◆

THE DEMAND FOR FASTER BATTLESHIPS.

In our issue of June 23 we called attention to the serious blunder which our Navy Department has made in fixing upon a speed of only 15 to 16 knots for the three new battleships for which it is now asking bids. We then showed that every naval power in the world except the United States has increased its standard speed for battleships to from 17 to 19 knots; that there are already at least fifty foreign battleships afloat or under construction which have speeds one to three knots in excess of the speed of any of our battleships; and that for the United States at this time to build new battleships with speeds even lower than the speeds of its battleships now afloat will injure its naval prestige as much as the loss of a battle.

Our prediction that if the American public once understood the significance of this action by the Navy Department, a universal protest would go up, has been amply verified. The presentment of this matter by Engineering News has been copied and commented upon by the principal newspapers in almost every city in the country, and our urgent plea that the Navy Department should revise its action and make plans for our new vessels that will put them at least on an equal footing with those of foreign countries in the matter of speed has been unanimously approved.*

Moreover, the newspapers are ably continuing the agitation for a change in the Department's plans. A number of the leading journals throughout the country have taken hold of the subject in earnest, and by repeated editorial presentations of the subject have awakened a public sentiment which the Navy Dèpartment must sooner or later recognize. Such journals as the "New York Tribune," "Brooklyn Eagle," "Pittsburg Dispatch," "Washington Times," "Minneapolis Journal," "Buffalo Enquirer," "Cincinnati Commercial Tribune," and others of similar standing the country over are urgently demanding that the naval authorities shall change their plans and make the new battleships vessels in which the nation can take just pride.

The only attempt by the Navy Department to justify its decision in any way that has come to our notice, is a Washington dispatch in the "New York Times," of July 8, in which "high naval officials" unnamed are quoted at some length. The substance of this reply we quote verbatim as follows:

> The fixing of a sustained speed of 16 knots an hour for our battleships was made after careful consideration of the question in all its bearings. It is an easy matter to increase the speed of ships, but without sacrificing their offensive and defensive qualities it can only be done by increasing their size.
>
> In consequence of the limited depth of water in most of the harbors on the American coast, it has come to be an unwritten law of naval construction in this country that the draft of the largest of our warships, in their normal condition, shall not exceed 24 ft. Most of the big battleships of European navies draw 27½ ft. Depth is a most important factor in increasing displacement, and as it is limited in this country by the shallowness of our harbors to 24 ft., increased displacement must be sought in either length or breadth or both.
>
> In designing a battleship of more than 12,000 tons displacement with the draft limited to 24 ft., the increased volume, if gained by lengthening, would result in a vessel of too great length for efficiency, increasing the weight of defensive material and reducing her handiness in squadron evolutions. If the beam alone be increased, the vessel would be too wide for many of our docks, and would afford an uneasy and highly unsatisfactory gun platform.
>
> It is further held by many naval authorities to be extremely doubtful whether a higher speed than 16 knots an hour would prove of practical value to a heavy fighting ship. For steaming long distances such a speed could not be used, and no squadron ever manoeuvred or was any naval battle ever fought at as high a rate of speed as that.
>
> A great deal has been said of the superior speed of Admirl Cervera's late squadron, but while those ships were credited with a speed of 20 knots "on paper" they never, from the time they appeared at the Canaries, showed an ability to "get there" at a higher rate of speed than ten knots. The fact that all four of them were overhauled and sunk by our cruiser "Brooklyn" and battleships of far less nominal speed, although the Spaniards had the advantage of a start at full speed, is convincing evidence of the futility of their boasted swiftness.

It is one unfortunate feature of the astonishing naval victories which have been won by the United States fleets in the present war that they tend to beget in the popular mind an over-confidence in the powers of our present naval vessels, and a tendency to overlook the weak points in our national defence. It is natural enough that the non-technical public should take the results at Santiago and Manila as conclusive proof of the efficiency in every respect of our fleets; but it is surprising, indeed, to find such arguments used by "high naval officials."

Further, as a matter of fact, the Santiago battle offers conclusive proof to the veriest tyro in naval strategy of the enormous value of high speed in a fighting vessel. Had the Spanish cruisers been able to reach such speeds as their engine power should have given them, even with their barnacle-laden hulls, the chances are good that they would have got out of range before the American vessels on guard could get under way and stop them. As it was, the fastest of the four, the "Cristobal Colon," did outstrip the other vessels and get entirely away and out of effective range. It was then that the "Brooklyn" and the "Oregon" undertook a stern chase after the fleeing vessel. The former vessel has about the same speed rating as the "Colon," but was not her equal in armor or armament; and in a duel between the two vessels fought with equal skill on both sides, the "Brooklyn" would probably have been worsted. What the result would have been had the two vessels fought alone will never be known, for the "Oregon," running at a 16-knot speed, was able to come to the assistance of the "Brooklyn," and made the defeat of the Spanish vessel sure.

The newspapers are accepting the Santiago battle as clear proof of the value of speed in a battleship, and they are right. For that matter, the statement of the "high naval official" that no battle was ever fought at a greater speed than ten knots is disproved at once by this very conflict. As for other naval battles, it is probably true that few or none have been fought with greater speed than ten knots, simply for the reason that very few naval battles have been fought with modern high-speed naval ships. Everyone familiar with naval warfare, however, knows that numberless actions have been fought with one vessel or fleet making all possible speed to escape and the enemy using every effort to overtake them. These are exactly the emergencies for which high speed in naval vessels is demanded.

The "high naval official" quoted above seems to think that the falling off in speed which Cervera's ships showed, is proof that the speeds of contract trial trips are no index of what a vessel can really do. But because that proved true with the Spanish vessels, it does not follow at all that it is true in the American navy. In fact the "Oregon's" speed in her chase after the "Colon" was very close to that recorded on her trial trip, notwithstanding the more or less foul condition of her hull.

Practically the sole argument that deserves to be considered in the above statement by the naval officials is the claim that the depth of our harbors limits the draft of American battleships to 24 ft., and the width of our dry docks limits their beam. Let us see how much there is to this argument. In the first place, it should be understood that there are only a few harbors on the coast which a 24-ft. draft vessel can enter at low water anyway. The list of ports with a depth of water of 24 ft. or more at low tide on the Atlantic and Gulf coasts is as follows:*

Port.	Depth, mean low tide, ft.
Portland	29
Portsmouth	(Admits any vessel.)
Providence	25
New York	30
Baltimore	27
Norfolk	25
Newport News	25
Yorktown	33
Key West	25½
Tortugas	24
Pensacola	24
New Orleans	26
Sabine Pass	24
Galveston	24

It appears that there are only 14 ports on our Atlantic and Gulf coasts which our present battleships when loaded to 24 ft. draft can enter at low water; but we fail to see that this is a matter of any particular consequence. So long as a battleship can reach the naval stations and dry docks where she is to be equipped and kept in repair, it is a matter of little consequence whether she can enter the other home ports or not. A glance at the above table shows that she can enter nearly as many of the commercial ports drawing 26 ft. as she can drawing 24 ft., anyway.

As for being able to reach the naval stations, battleships of any desired draft can reach the Portsmouth and New York navy yards, and the same is true of the anchorages at Hampton roads and Dry Tortugas. To get up to the berths at the Norfolk yard, some dredging would be necessary for a vessel of 26 ft. draft or more; but if the United States can afford to spend as many million dollars as it proposes to upon new ships, it can afford whatever may be needed to dredge the channels leading to its principal naval stations. For that matter, if our largest battleships can reach the four stations named above we do not see that they need further accommodation.

Let us turn next to the matter of dry dock accommodation. At present we have just three docks on the Atlantic coast which can take in battleships of the dimensions now proposed (excluding the Port Royal and League Island docks, which are inaccessible to our present battleships by reason of shallow water). Congress has just appropriated the funds for five new docks. We know of no reason why these structures should not be made wide enough and deep enough to take in whatever size of battleship the conditions of National defence makes it wise for us to build.

When one really stops to think of it, how absurd seems the declaration, that this country has settled down to a basis of a 24 ft. draft and a 16-knot speed as a permanent limit for its battleships. Other nations may progress as they please, 16 knots is fast enough for us! How long is this standard to last, pray? Are we to continue placidly on that basis, no matter what progress other nations make, until perhaps in some future naval battle the superior speed and manoeuvering power of an enemy's fleet may win them the day?

There have been various conjectures as to the reasons why the Navy Department adopted this low rate of speed for the new vessels. It has been alleged that the three or four great shipbuilding firms who will doubtless take the contracts for them wanted to build duplicates of the vessels of the "Alabama" class now under construction to save the expense of duplicating drawings, patterns, templates, etc., and increase their profits. We do not believe this to be true. Neither do we believe that the Navy officials merely wished to save themselves the trouble of making new designs throughout for these three ships.

We believe the real reason is a sort of ultra conservatism that prefers to follow the beaten path to making any new ventures and prefers to sit comfortably down and rest content with 24 ft. draft and 16-knot speed, rather than to attempt to follow English and Continental naval designers in the vast strides which they have made in the past four or five years.

---

*We say unanimously, but in the interest of absolute accuracy, we must record that one Philadelphia newspaper thinks 15 to 16 knots is fast enough.

*This list includes the depth of water up to the wharves in each case. Of course there are harbors of refuge, and places of anchorage all along the coast, as at Key West, Hampton Roads and numerous points all along the North Atlantic coast where vessels of any draft can lie at anchor in more or less shelter.

We have abundant authority for declaring that the American people will not rest content with naval progress of such a sort. The people as a people want no wars; they vastly prefer the arts of peace. They want no huge naval establishment and had rather build schools than battleships and factories than fortresses. At the same time they will cheerfully and gladly contribute all that is necessary to make their national defence impregnable on land and sea; and, thanks to our fortunate position, far less suffices to effect this for us than for any other country. But in these national defences they will brook nothing of a second-rate order. American armor plate is equal to any in the world. American guns are on a par with those of any country. Why should not American battleships be made equal in speed and manoeuvering power to those of any nation? We have given the sole reason which has thus far been put forward, which deserves any credence, that of our shallow harbors, and we have shown that there is actually no serious obstacle in the way of adopting greater draft for our battleships if that is really an essential to their higher speed.

We have no doubt that a large factor in the decision of this matter made by the naval authorities was the fact that it was made at a time when the pressure of other duties was well-nigh insupportable. In the rush of providing for the actual immediate necessities of warfare last May, there was scant time to spare for the solution of any difficult problems in connection with the design of new vessels. But that rush is now past. We are in no serious need of these three new battleships, and do not want or expect to be. With the five vessels now nearing completion, our navy will be as strong in battleships as any nation in the world except England, France and Russia.

It will be vastly better for our national defence to wait a year longer, if necessary, for these three additional vessels, instead of rushing ahead with their construction on lines which every other naval power in the world has discarded as obsolete.

LETTERS TO THE EDITOR.

Springs for Freight Car Trucks.—Correction.

Sir: In the issue of Engineering News of June 23, p. 412, where the standard spring coils, recommended by the committee of the Master Car Builders' Association, are given, is there not an error of some sort? The spring marked "A" does not seem to harmonize with the rest. Perhaps it was 15-16-in. diameter of wire until the compositor got hold of it. I am likely to make some use of these figures and so am particularly interested in correctness. Yours truly,

C. M. Spalding.

Schenectady, N. Y., July 6, 1898.

(The diameter of the wire in spring A should be 15-16-in., the error was made by the compositor, as our correspondent surmises.—Ed.)

A Test of Mechanical Filters at Moscow, Russia.

Sir: After my inspection of American and European filters, I proposed to the Councils of the Municipality of Moscow to undertake experiments with different systems of mechanical filters. Both councils adopted this project, and at the session of June 21 appropriated for the experiments 65,000 rubles (about $32,500). This sum will be sufficient, because necessary pumps and boilers are already at our disposal. The general arrangement of the experiments will be similar to that which I, through the kindness of Mr. Chas. Hermany and Mr. Allen Hazen, have seen in Louisville, Ky., and Pittsburg, Pa.

I consider the matter of great importance, because according to the results of the tests the matter of our future Moscow River water supply (first for 10,000,000 and afterward for 40,000,000 gallons daily) will be settled; and I think that every large city, having a water supply from open sources, ought to undertake such tests, because the results of filtration are apt to be different, according to the conditions of the water to be filtered.

We immediately take steps towards the execution of the ordinance of the Municipality of Moscow, and shall continue the tests for about one year.

I remain very respectfully yours,

Nicholas Simin,

Chief Engineer of Moscow Water-Works.

Moscow, Russia, June 28, 1898.

Cost of Heating a Factory Built of Steel and Glass.

Sir: Our attention has been called to an article published in your issue for July 7, 1898, describing our factory building, and we note your remarks in regard to the cost of heating the same. The power for running our shop is obtained from the local electric light company, so that our boiler is used for heating purposes only. During the past winter, from Nov. 1 to July 1, we burned about 86 tons of coal, costing $3.25 per ton, a total of about $280, and only about half of the fireman's time was chargeable to the care of the boiler and heating plant, so that we feel that $500 would cover the entire cost of heating the building.

In the description which you publish, no mention was made of the fact that the upper portion of all of the windows is double glazed, an air space of ¾-in. being left between the inner and outer panes of glass. The outer pane of glass is, as stated, of corrugated or roughened glass, and the inner pane of ordinary window glass. The lower part of every window is swung on the center instead of every other panel, as stated in your description. The lower sashes are at present single glazed, but are so constructed that another pane of glass can be inserted whenever desired, and it is probable that this will be done before next winter.

It is possible that next winter we may make some tests as to the actual amount of steam required for a given temperature of atmosphere, and will be pleased to send you any data of this kind which we may obtain.

We are pleased with our building and would adopt the same method of construction for any similar buildings which we may erect hereafter.

Yours truly, The Veeder Mfg. Co.,

C. H. Veeder, Pres.

Hartford, Conn., July 11, 1898.

Breakages of Electric Railway Car Axles.

Sir: Enclosed herewith please find an impress of the fractured end of an electric car axle which recently broke in this city. It is remarkable chiefly for showing that some previous action had taken place before the final rupture. That portion of the fracture most completely shaded was as smooth, when first observed after the accident, as if it had been cut with a cold chisel. The blank square spot in the impress is where the head of a key held the gear on the shaft. The rest of the fracture was that of a very fine grained steel and showed no marked peculiarities. A trace of rust was observable about the head of the key but not elsewhere.

In the past five years, five similar accidents have occurred to electric cars in this city. In two of them which came under my notice a similar condition (though not so marked) was shown, i. e., as if partly cut with a chisel. Is the same true of like fractures to seam car axles? Or is it only under the influence of electric power? In each case I have observed, it has been a driving axle which broke.

There were about 100 street cars in use when these accidents occurred; or, to put it another way, about 1% of the cars have had similar breakdowns. This would appear an excessive ratio.

The mileage run by the cars differed; but in all cases the length of run would seem to have been sufficient to have exposed any original inherent defects. It was usually more than 100,000 miles and less than 300,000. In the present case it was the forward axle under an electric dummy used to haul two flats loaded with wood through the city streets to the power house. A 20-HP. T-H. motor was geared to it at the line of fracture. The car ran on two four-wheel trucks, with a motor on each axle. It had run about 125,000 miles at the time of the accident.

Will some one else give information tending to throw light upon this subject? It may lead to some better method of inspecting than the present superficial one, and thereby assure greater freedom than at present from recurrence of such accidents. Yours truly,

A. McL. Hawks.

Tacoma, Wash., July 8, 1898.

(The "impress" which our correspondent sends is an impression on paper made by the broken end of the axle after blackening it with something like printer's ink. The axle was 3½ ins. diameter. The smooth part of the fracture is about 0.4 of the total area, the division between the two parts of the fracture being nearly a straight line. This kind of fracture is not at all unusual in steam car axles; in fact it is the most common way in which any axle breaks. Sometimes the original break runs all around the circumference, making a smooth annular ring half an inch to an inch deep, this fracture being progressive through a long time, say a month or more, and then the final break takes place showing the ordinary steel fractured surface. It appears that the breakages of electric car axles are much more frequent than those of steam car axles. We believe the reason is that they are not made strong enough for the work they have to do. They are subjected to both torsional and transverse strains in reversed directions, to sudden stoppings and startings, and to violent shocks from irregularities of track to a greater degree than the ordinary steam car axle. When the electric railway companies use the same precautions to insure the long life of their axles that the leading steam railways do the average life of the electric railway axle will be greatly increased.—Ed.)

A New Moment Formula for Concentrated and Distributed Loads.

Sir: The communication on "A New Formula for Concentrated and Distributed Loads," in your issue of June 23, illustrates how complicated an extremely simple matter may be made to appear. It is a well-known law of mechanics that the bending moment is maximum or minimum (maximum in the case of a simple beam) where the shear passes through 0. Considering the case assumed, that of a simple beam (1) uniformly loaded for its entire length, and (2) carrying a single concentrated load, it is evident that the shears from (1) and (2) respectively are opposite in character only for the distance from the center of the span to the point of application of the single load. The section of maximum bending moment must lie then somewhere along this distance. Using the notation employed by your correspondent, the following equation follows directly from the law above stated:

$$\frac{P\,a}{s} = \frac{W}{s}\,y_1, \text{ or } y_1 = \frac{P\,a}{W}.$$

As stated by your correspondent, if y_1 is greater than $\frac{l}{2} - a$, the limiting case is indicated and the bending moment is then maximum at P.

Yours truly, E. M.

Philadelphia, Pa., July 1, 1898.

Sir: In your issue of June 23, 1898, there is a communication entitled "A New Moment Formula for Concentrated and Distributed Loads." This is similar to a formula which I have used and for which I submit the following proof, which is shorter than that given by your correspondent, and which it seems to me may be clearer to a part of your readers.

Let w = the uniform load per linear unit;
l = length of span;
P = the concentrated load; and,
a = its distance from the nearer support.

Then the expression for the bending moment at any point at a distance x, greater than a, from the same support is

$$M = \frac{P\,(l-a)\,x}{l} + \frac{w\,l\,x}{2} - P\,(x-a) - \frac{w\,x^2}{2}.$$

Placing

$$\frac{d\,M}{d\,x} = 0,$$

and solving for x, to find position maximum M, we obtain:

$$x = \frac{l}{2} - \frac{P\,a}{w\,l}.$$

To transform this into the form given by Mr. Lepper note that $w\,l = W$ and that $x = \frac{l}{2} - y_1$.

Yours respectfully, Elton D. Walker,

Asst. Prof. Civil Engineering, Union College.

Schenectady, N. Y., June 27, 1898.

Sir: In the issue of June 23, 1898, of Engineering News, is published a letter entitled "A New Moment Formula for Concentrated and Distributed Loads," the author of which thought he had discovered and given to the engineering world a new formula for finding the exact point of maximum bending moment of a beam, supported at both ends and loaded with a uniformly distributed and one concentrated load.

As a matter of fact, a diagram similar to the one given by the writer is found in Hatfield's "Transverse Strains," page 179; where he also deduces the same formula. Hatfield makes his parabola representing the bending moment due to the uniform load above the horizonal line connecting the reactions, and the triangle representing the bending moment due to the concentrated load below said line, while the article by the writer simply reverses this order. Hatfield then proceeds to find the greatest bending moment by drawing a tangent to the parabola and finding the longest line inside the figure formed by the curve of the parabola and the lines of the triangle. Then follows an analytical demonstration to determine the point of maximum bending moment, which I will not burden your readers with, as those who wish may find it on the page of Hatfield cited, but arriving at a conclusion giving the following formula:

$$h = \tfrac{1}{2}\,L + \frac{A\,m}{U},$$

in which L = span; A = concentrated load; m = distance from concentrated load to nearest support; U = uniform load; and h = distance of greatest moment from the most distant support.

This is the same formula as the writer's except that the latter's result gives the distance of the point of maximum bending moment from the center of the span, whereas Hatfield's result gives the distance from the abutment, or the former distance, plus one-half the span.

The edition of Hatfield referred to was published in

1877, and we have been using the formula for years, in fact ever since our engineering department was established. Yours very truly, Dudley McGrath,
Structural Engineer.

Office of Jno. B. Snook & Sons, Architects, 261 Broadway, New York city, June 25, 1898.

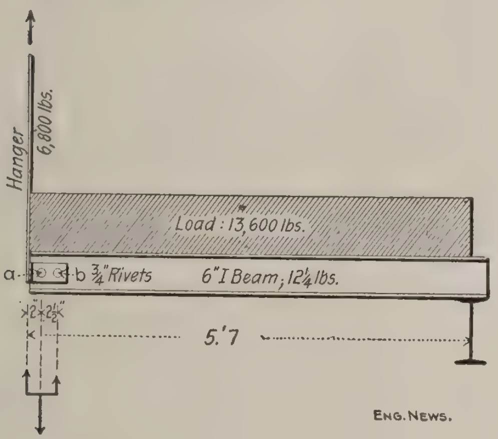
◆

Erroneous Data in Manufacturers' Hand-Books Concerning Structural Beam Connections.

Sir: The issue of a new and enlarged edition of their hand-book by the Cambria Iron Co. has brought to notice the fact that the hand-books issued by the Cambria Iron Co., the Carnegie Steel Co., Ltd.; the A. & P. Roberts Co., and Jones & Laughlins, while excellent in most respects, all contain a table of "minimum spans of I-beams for which the standard connection angles may be safely used with I-beams loaded to their full capacity," which is seriously in error.

This table has been prepared on the assumption that all the bolts or rivets joining the connection angles to the ends of a beam are strained to equal amounts and in the same direction. The fallacy of this assumption was shown in the Engineering News of May 16, 1895, in an article on "Standard Beam Connections." It is due to the authors of the table in question to state that in preparing it they have followed the method in general use. It probably has not occurred to them to question its practical accuracy, and they will doubtless be surprised on investigation to learn how seriously it is in error.

The table indicates in all cases a greater capacity for the connections than they would have under the limits for bearings and shearing on which the table is alleged to be based, the errors being comparatively small for deep beams and very great for shallow ones. As an illustration of one of the cases of great error, the length and load given as corresponding to the standard connection for a 6-in. beam is taken from the Cambria Iron Co.'s hand-book (the books of any of the companies mentioned could be used with substantially the same result), and the maximum bearing stress is analyzed.



As the safe load (as shown in the accompanying cut) is 13,600 lbs., the end reaction is 6,800 lbs., and the load on rivet a is found, by taking moments about the center of rivet b, to be 12,300 lbs., or 71,000 lbs. per sq. in. of bearing surface, as compared with an extreme fiber stress in the beam of 16,000 lbs. per sq. in.

While this analysis shows clearly that the table greatly overstates the capacity of the connection, it is not expected that the result obtained indicates the actual facts with mathematical precision, because no account has been taken in the analysis of the stiffness of the hanger or the clamping effect of the rivets.

In the article in Engineering News above referred to a method for determining the capacity of beam connections is proposed which, while open to criticism, gives much more reliable results than that on which the table is based.
Respectfully, Henry S. Prichard.
Trenton, N. J., May 6, 1896.

(In accordance with our usual practice a proof of Mr. Prichard's letter was sent to the publishers of the different pocket-books mentioned in order that any reply they might desire to make to the criticisms therein might be published in the same issue. With the exception of the Pencoyd Iron Works, whose answer we append below, only one reply was received to our letters, and this firm has not yet sent us any matter for publication. We therefore, publish the matter thus far received without waiting for further replies.—Ed.)

Sir: It is of such importance in steel floor beams and similar structures that the end connections should have as great a carrying capacity as the beam itself, that the criticisms made by Mr. Prichard, under date of May 6, 1898, and more fully in your issue of May 16, 1895, are entitled to careful consideration.

Opportunities occasionally occur in finished structures where it is possible to compare the strengths of the beam and its end connections, and we do not know of any instance where the joints indicated such weakness as Mr. Prichard has suggested. In Vol. XXXVII. of the Transactions of the Am. Soc. C. E., Mr. Julius Baer records the effects on buildings of the St. Louis tornado, and especially notes the persistence of the riveted end connections of beams when the supported beam was entirely destroyed, and remarks: "Any standard floor beam connecting angle is probably of ample strength if subjected to only such treatment as it will receive in a floor." This accords with isolated cases within our own experience.

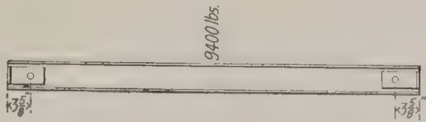


Fig. 1.—Test of the Effect of Friction Between Angle Connections and Web of Beam.

Mr. Prichard probably underestimates two elements of resistance—the frictional resistance, caused by the grip of rivets, and also the partial "fixedness" or continuity due to the rigid attachment of the end angles to their outer supports. Experiments have proved an increased strength of about 10% of a riveted joint over a similar joint held by fitted pins without heads. This refers to rivets 3/4-in. diameter; the gain is less on smaller and more on larger rivets. As the friction is presumably constant, it would probably represent about one-fourth the total working resistance of the joint.

To test the effect of the friction between the angles and web of the beam, a 6-in. I-beam had angles riveted on with a single rivet, as shown in Fig. 1. These were 3/4-in. rivets filling 13-16-in. holes, spaced 3⅝ ins. from the end of angles or midway between the two rivets of the standard joint. Pressure was applied at the middle and it was found to require a load of 9,400 lbs. before any indication of slipping between the parts was observed. This corresponded to a turning moment of 17,000 in.-lbs. due only to friction.

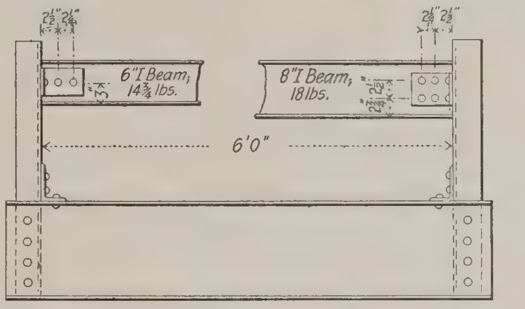

Fig. 2.—Test of Standard Angle Connections.

The following experiments were made on 6-in. and 8-in. I-beams, these small sizes being taken, as the criticism referred to says the "error is very great for shallow beams." The spans were about the minimum recommended by the hand-books. The beams were connected to a stout frame, which represented the usual conditions of end attachments, the attaching angles being the standard of the Pencoyd Iron Works, as shown by Fig. 2. These beams were subjected to pressure at mid-span in the testing machine. No visible effect in either case was discernible at the joint until the elastic limit was much exceeded, when the deflection of the beam caused a yielding of the angles near the root and bending of the exterior flanges around the connecting rivets, as shown in the photographs, Figs. 3 and 4. But when the bending was carried so far that the beams were entirely destroyed, there was still no indication of the slightest yield by slippage or otherwise of the attachment of the angles to the web of the beams.

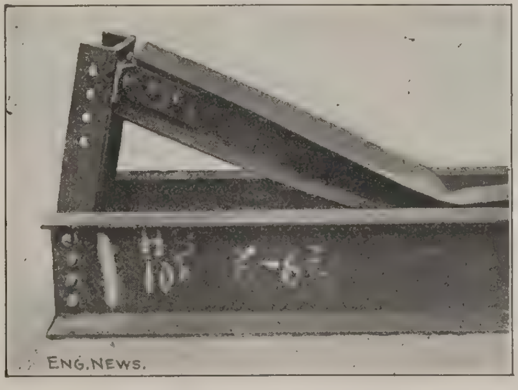

Fig. 3.—Condition of Connecting Angles on 6-in. I-Beam After Failure of Beam.

To demonstrate further the influence of rigidity at the end attachments, two beams of the same section, with the end supported but not rigidly attached, were tested with the angle attachments resting freely upon supports, Fig. 5. The initial deflections on the beams of the same size showed little difference due to the nature of the end supports, and the measurements were not made with sufficient accuracy to establish this difference. As the stresses approached the elactic limit the differences were more marked, and the beam with riveted ends sustained about 20% more load than the similar beam with free ends before any permanent set occurred.

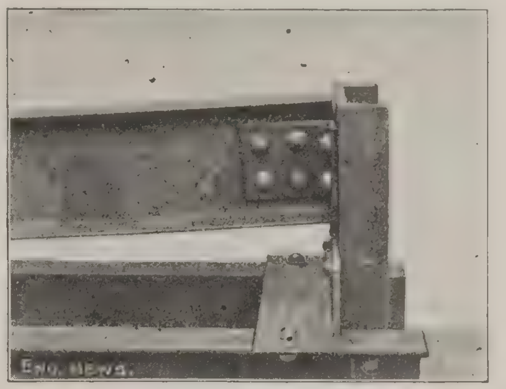

Fig. 4.—Condition of Connecting Angles on 8-in. I-Beam After Failure of Beam.

Table Showing Pressures at Which Permanent Set Began.

Size of beam, ins.	Wgt. per ft. in lbs.	End connections.	Load in lbs.
6	14¾	Free ends.	15,000
6	14¾	Rigid ends.	18,000
8	18	Free ends.	25,000
8	18	Rigid ends.	30,000

In the free end beams, as in those with rigid ends, there was no indication of the least yield between the angles and the web of the beams.

The shearing and frictional resistances act in conjunction, and the strength of the joint is represented by their sum.

The influence of the rigidity of end attachment depends on its extent. If the attachment was sufficiently rigid to render the beam as strong at the ends as in the middle, the moment at the rivets would be as great as at the center of the beam with a concentrated central load. But a connection whose influence was less than aforesaid would only tend to counteract the moments proceeding from the reaction. The influence thus exerted in the case of beams tested had probably one-fourth the effect of fixed ends.

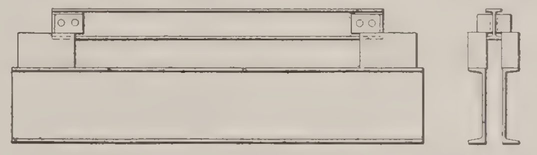

Fig. 5.—Test to Determine the Influence of Rigid End Supports.

OBSTRUCTIVE BRIDGES AND DOCKS IN THE CHICAGO RIVER.*

By G. A. M. Liljencrantz, Mem. W. S. E.

The Chicago River has been and is of enormous value to the commerce of the city, through its large and extensive lake traffic. Its dimensions some 30 years ago were ample for the commerce and traffic of that time, but in recent years almost everything in the city been "kept up with the times"—except the river. To be sure, it has been improved. Miles of docks have been built, periodical dredging has been done, and improved bridges have been built, but the question is: "Has the improvement of the river been kept abreast with other improvements in this great and rapidly growing city?" And another question which, in the writer's mind, is still more serious: "Are existing conditions such as to admit of an improvement of the river that will be commensurate with a metropolis of three or four million inhabitants, as Chicago no doubt will be but a few decades hence?" When studying the conditions we find much cause for discouragement.

Increased depth has been secured to some extent by occasional dredging, but it is again regularly decreased by the unceasing deposits from the numerous sewers emptying into both branches of the river, as well as by constant sweeping and dumping of refuse in various ways into the channel, requiring frequent redredging. But this removable material forms the least serious obstacle in the way of the vertical improvement. Not less than three tunnels cross the river, with their crowns at an elevation which, at the time they were built, allowed sufficient draft for the navigation of that day, but which now form the gravest obstructions to the much larger vessels of deeper draft of the present time.

---

*Abstract of a paper presented at the meeting of the Western Society of Engineers on June 1. The abstract is published by permission of the Society, and the paper in full, with the discussion, will be published in the Society's "Journal."

Docks are frequently built with more consideration as to cheapness in first cost than to future needs and are thus made only of strength enough for the existing depth of water, and are accordingly subject to undermining, whenever the channel is considerably deepened. An extensive deepening, even if the obstructive tunnels did not exist, would accordingly involve great expense to individual owners, in addition to the direct improvement by dredging, and to make such improvement practically permanent it will be necessary to dispose of the sewage by a different method from that now employed, or provide for continuous maintenance by dredging.

Let us next look at the difficulties we encounter in planning to widen the channel. Vessels of even the greatest dimensions in use until about 1890, and which still constitute the great part of the lake fleet, easily pass any part of the navigable river, but some of those built within the last few years find it impracticable to enter either of the branches of the river, or, when loaded, to pass the first of the "artificially constructed reefs," the La Salle Street tunnel. The manner in which a long vessel has to move to make this passage possible is illustrated in Fig. 1, showing the river between Clark and Wells Sts., with the tunnel half way between. The available channel is here in the middle of the stream. A vessel 48 ft. beam and 432 ft. long (which is the length of the longest boat now navigating the lakes) represented as coming through the north draw of Clark St. bridge, turning to the deeper channel in the middle, over the tunnel. It is compelled to proceed thence across to the south draw of the bridge at Wells St., because the turn to the north draw of that bridge is practically impossible, for there is only 500 ft. between the two bridges, and the center channel has a depth of 17 ft. at low-water over the restricted width of only 62 ft. on the line of the center piers of the bridges. Center piers and projecting docks obstruct the channel at numerous points. The Chicago & Alton R. R. bridge, north of Archer Ave., is a striking example of how some bridges are constructed without the least regard for the demands of navigation. Too narrow are also the draws of the three bridges in close proximity at Kinzie St., in the north branch of the river, as well as at the Indiana St. bridge. Nothing larger than a tug can pass the east draws of the first named three bridges, which, in fact, had never been dredged until in April of this year. At the Division Street bridge neither draw can be used, nor can those of the North Ave. bridge be used by such large vessels.

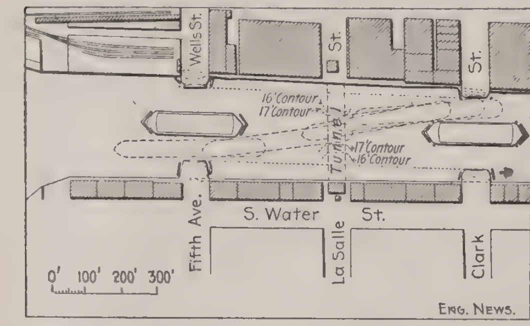

Fig. 1.—Course of a Large Steamer in Crossing the La Salle St. Tunnel; Chicago River.

One of the worst places on the north branch is the sharp bend forming an S-curve at the crossing of the C., M. & St. P. Ry. bridge, south of Clybourn Place, and nothing but the most radical alterations can make this part of the river, or that above, accessible to vessels of the type here represented, and it is therefore thought unnecessary to occupy more time and space in describing the obstructions found above this place, which are generally equally bad, and some perhaps even worse.

The chief reason for the deplorable condition of the river, as regards its many obstructions, I consider to be the total absence of any well defined system of improvement, by way of legally established dock, or channel lines. The owners of water front along the river seem to have built their docks with the sole consideration for their own individual advantage, in such manner as to make as much land as possible, out of what should properly be the channel, apparently in utter disregard of the demands of navigation. Dock lines have been established, to be sure, in detached places, but as far as I have been able to discover, not in conformity to any general system. By an ordinance passed June 11, 1869, or 29 years ago, there were established certain dock lines along a portion of the south branch. Provisions were made in this ordinance for assessments to pay for the condemnation and purchase of land, required to comply with the terms of this document, but nothing further has been done in the matter, and numerous docks have since that time been constructed without the least regard to the dock lines so established, judging by the conditions now existing.

By an act of congress of June 3, 1896, making an appropriation of $50,000 for improving the Chicago River "from its mouth to the stock yards on the south branch and to Belmont Avenue on the north branch as far as may be permitted by existing docks and wharves," the work of improving this river by the United States government was inaugurated.

The only work that could be done, however, in compliance with the wording of the bill, was dredging. Bids were advertised for and received, and contracts let for the execution of this work, which commenced in November, 1896. The project approved by the Secretary of War contemplates the deepening of the channel to 17 ft. below the city datum, the bill providing for dredging to admit passage by vessels drawing 16 ft. of water. The existence of the tunnels would make a greater depth useless.

The work of dredging has been done from the mouth to the stock yards in the south branch, and a part thereof has been redredged, viz.: From the south limits back to Twelfth St., and this work is now nearing completion towards the harbor. In the north branch the work has been done from the junction to Fullerton Ave., and when the northerly limit is reached the whole of that branch will also be redredged.

Up to May 1, 1898, there have been removed from the main and south branches, in round numbers, 540,000 cu. yds. and from the north branch 658,000 cu. yds., or a total of 1,190,000 cu. yds. The sum of $113,000 was appropriated in a later act of congress, for the completion of this part of the river improvement, and authority was by this later act also granted for entering into contracts for work in widening the channel, such work to be limited by the sum provided for that purpose, to-wit: $700,000, including the amount required for the dredging. This work is thus confined to the removal of only the most obstructive of the many protruding dock corners.

The greatest obstruction to navigation are the tunnels and bridges, which are corporate property, and it is questionable whether the government would ever consider the navigation in the river so necessary to the general commerce of the nation to condemn such valuable property, and either to compel the removal of the obstructions caused thereby, at the expense of the owners thereof, as can be done under existing laws, or to undertake the enormous expense of rebuilding or remodeling the structures at the expense of the public treasury.

To decide upon a plan of improvement, which will furnish the greatest relief to navigation, authorized by the bill and at the same time keep the cost within the prescribed limits, a study was made, on the maps, of the various corners and bends in the river to learn to what extent these would interfere with the passage of a vessel of the type described. The vessel was represented by a pasteboard model made to the same scale as the map. In this manner the most obstructive dock corners were selected and improvement of these places recommended, consisting in the removal of a sufficient amount of the protruding land to facilitate the passage of the largest vessel.

Examples of this work are shown in Figs. 2 and 3. At the so-called "Collision Bend," some 700 ft. east of Halsted St. bridge, Fig. 2, 15,965 sq. ft. have already been removed by the Sanitary District and 7,702 sq. ft. are to be removed by the government. The name of this place is a brief but fair intimation of the conditions here. Fig. 3 shows the Illinois Steel Co.'s property, the north part of which forms an obstruction to the passage of vessels through the west draw of Archer Ave. bridge, and is to be removed. The river is furthermore very narrow all along this property and in all 18,790 sq. ft. are to be taken off therefrom. Across the river from the steel company's land is a protruding corner, where 1,693 sq. ft. are to be removed, as shown.

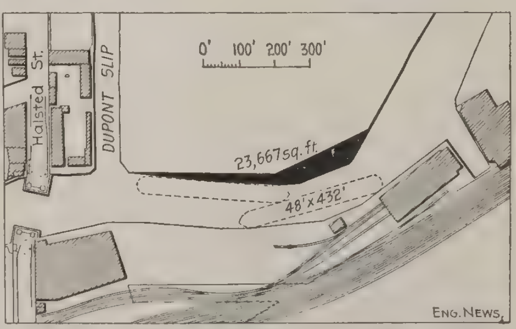

Fig. 2.—Improvement of the Chicago River at "Collision Bend." (U. S. Government Work.)

The whole project contemplates the purchase and removal of 123,100 square feet of land and the construction of 4,790 linear feet of dock, in front of the removed land.

All the principal preliminaries for this work have been completed. All that is needed for commencing active operations is the necessary appropriation; and Congress holds the electric button, a touch upon which will set the wheels of activity in motion.

THE DURABILITY OF MARBLES AND GRANITES.

At the meeting of the Civil Engineers' Club of Cleveland on July 12, Mr. Oliver S. Hubbell read a paper on the above subject, in which he described his investigations as architect for the Wade Memorial Chapel and Receiving Vault. His instructions from his client were to find a building stone which would last for 500 years. We abstract the paper as follows:

The surface of marble soon disintegrates in the climate of Cleveland, and becomes granular as well as discolored. Old tombstones in the city graveyards show this. However, a protective fluid may be used, with which the marble may be saturated, so as to become weather-proof and thoroughly durable. South Dover and Tuckahoe marbles are used in New York city. The Lee marble is largely used in Washington and Philadelphia, but this has a bluish gray tinge. It has certain defects called "shakes," and contains some particles of magnesia, which dissolve in wet weather and leave the surface pock-marked. The Vermont marbles were examined also, in the quarries and in buildings. No old marble was found in New York city that is not more or less discolored and disintegrated. The top surfaces are both rough and dark, while the under sides of projections are in good order. The Vermont quarries are probably the largest marble quarries in the world. These are at Proctor and East Rutland. The buildings of the Quarry Company are built of marble taken at random without selection. They are therefore quite mixed in color, and give a really fine architectural effect. The Rutland marble is easily cut into fine lines and ornamental figures. On the other hand, Georgia marble is hard to cut, and unless great care is used large crystals will break out in cutting.

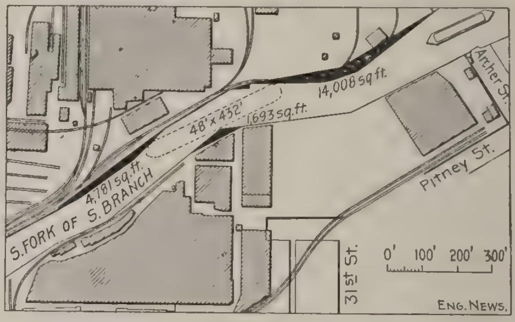

Fig. 3.—Improvement of the Chicago River, near Archer Ave. (U. S. Government Work.)

Granite is refractory and has to be tooled by hard and patient labor. Pneumatic tools have been invented for under cutting, but plain surfaces are generally worked by hand. Granite does not lend itself to fine ornamental lines, and its gray color prevents the best effects of light and shadow.

Of all the granites, the North Jay seems to have the lightest color. Grant's tomb and the new Bowling Green Building, New York, are built of this. It is, however, rather porous and soft, and occasionally discolored by iron. A few defective blocks may spoil the effect of an entire building. Westerly granite is the darkest of all. The Concord granite is used in the Library Building at Washington. It contains some particles of magnesia. The Troy, N. H., granite is light and sound and of good quality. The Halliwell granite was used in building the State Capitol at Albany. Barre has the most prolific quarries in America, but the product is liable to have iron in it, at least in the sap. Small specks of iron hardly detected in the first instance will later dissolve and streak the whole surface. However, it has been used for twenty-five years, and some monuments built of it are still as good as new. The Halliwell granite is the best and most expensive, and is largely used for monumental work. It is homogeneous, all sections presenting the same appearance in whatever direction they are taken.

It was finally decided to use either the Troy or the Barre granite in the Memorial Chapel.

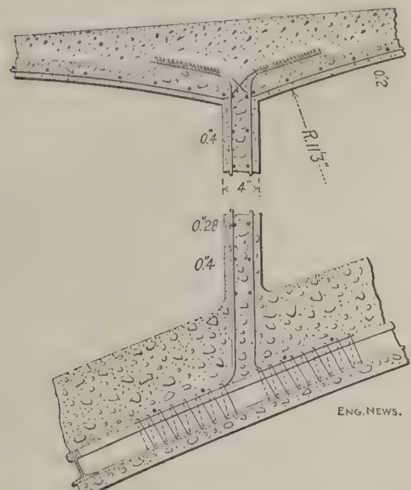
In conclusion Mr. Hubbell stated that although Mr. Wade was recommended by friends to go to New York, or even to Europe, to select his architect, he nevertheless decided that this building should be designed and constructed by Cleveland architects.

The speaker exhibited one sample of white Italian marble, which had been exposed to the Cleveland climate for years, till its surface was black, and it had so far disintegrated that it could be crumbled between the thumb and finger.

◆

A NOVEL EXAMPLE OF CONCRETE AND METAL BRIDGE CONSTRUCTION.

The accompanying cut illustrates a novel manner of employing concrete and metal in the construction of a foot bridge, which is described in a recent issue of the "Zeitschrift des Oesterreichischen Ingenieur und Architekten Vereins." This bridge serves the purpose of carrying a footpath across a double-track railway in the vicinity of Copenhagen, Denmark, and it has a clear span of 21.85 m. (71.7 ft.), with a rise of 2.58 m. (8.45 ft.). The depth of the arch ring at the crown is 25 cm. (9.8 ins.), and at the springing lines 36 cm. (14.2 ins). The intrados of the arch has a radius of 23.54 m. (77.23 ft.) at the crown which is increased to 26.68 m. (87.53 ft.) at the abutments. The concrete arch is stiffened by five parallel ribs, spaced about 0.75 m. (2.5 ft.) apart; the ribs being bent rails joined together longitudinally and weighing 28 kg. per m. (18.8 lbs. per ft.). The walk across the bridge, which is 3.14 m. (10.3 ft.) wide, is carried by Monier arches 5 cm. (2 ins.) deep, and having spans of 2.24 m. (7.35 ft.) These arches are supported by pillars only 10 cm. (4 ins.) thick, standing upon the main arch ring.



Sketch Showing Method of Employing Concrete and Metal for a Foot Bridge at Copenhagen, Denmark.

The iron net in the Monier arches is made of wires 5 mm. (0.2 in.) thick, spaced 10 cm. (4 ins.) apart. In each of the pillars there are two nets composed of 10 mm. (0.4 ins.) square vertical rods, tied together by 7 mm. (0.275 in.) thick horizontal wires. As shown in the cut, these nets are secured at the feet of the pillars to the iron rails by wire wrapping, while at the top they are connected with the net in the main arch. The proportion of concrete used in the main arch, the small Monier arches, and the pillars, was 1 part Portland cement to 3 parts of gravel. For the abutments and the filling over the small arches the proportions were, 1 part cement, 4 parts sand and 7 parts gravel.

The bridge was built in the spring of 1879, and cost about 8,000 marks, or about $1,900. It is stated by our contemporary that a similar but larger bridge, designed by Mr. Melan, is to be built in Austria. This bridge will have a roadway 6 m. (19.7 ft.) wide for street traffic. The span will be 42 m. (137.8 ft.), with a rise of only 2.85 m. (9.35 ft.). The main arch will be reinforced by lattice girders, and will be hinged both at the center and at the ends.

TWO NEW SAFETY APPLIANCES FOR DERRICK ENGINES.

We illustrate herewith a safety lock and a friction clutch recently applied, by the Lidgerwood Mfg. Co., New York city, to the derrick hoisting engines which it builds. These devices are attached respectively to the foot brake of the boom fall drum and to the hoisting drum and are designed to enable the operator to control the hoisting and boom motions more certainly than with the ordinary appliances. It is claimed that with these attachments the engineman can handle the engine with much more rapidity and with perfect safety to the men below the derrick.

The new engine is substantially the Lidgerwood standard friction drum engine with the addition of the safety lever lock attached to the foot brake of the boom fall drum and the friction lever latch on the hoisting drum. The friction lever latch (Fig. 1) enables the engineman to hold the drum in any desired position, as, for example, when taking up a load with the hoisting fall and desiring to lower the boom at the same time. In such a case the friction is thrown in on the hoisting drum and it is impossible through any slip or inattention for the load to drop, and the operator may give his whole attention to the lowering of the boom. With the safety lever lock (Fig. 2) on the foot brake of the boom fall drum one motion of the foot sets the brake, which cannot be released without throwing the friction in position, and when this is done it automatically releases the foot brake and holds the catch away from the brake till the boom is put in the desired position, when the brake is again set with the foot. By the old method the engineman had to give his attention to the two friction drum levers, two foot brake levers, two ratchets and pawls, and the steam lever, gathering himself into an awkward position in which it was almost impossible for him to follow the load and watch the signal man at the same time. In operating a double drum derrick engine, where the safety appliances have been attached, the engine man stands erect, and in a natural and easy position, and is thus enabled to see every signal whether given from the pit or from the point where the load is dumped, both hands and feet being available for handling the boom while the load is being hoisted.

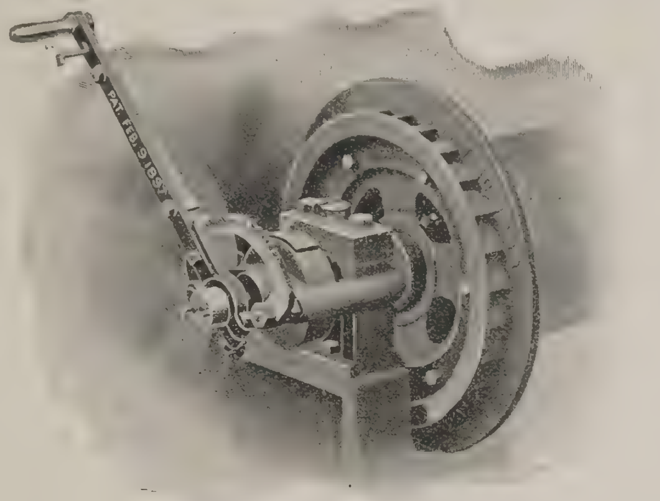


Fig. 1.—Lidgerwood Friction Lever Latch for Hoisting Drum of Derrick Engine.

We are indebted to the Lidgerwood Mfg. Co. for the illustrations and for information from which this description has been prepared.

◆

THE PNEUMATIC MAIL TUBES across the Brooklyn Bridge are practically completed, and it is expected that a test will be made before the end of the week, although it will be several weeks before the line will be put in continuous operation. It will be remembered that this installation consists of two 8-in. pipes between the New York and Brooklyn post offices, together with the compressors and other auxiliary apparatus.

◆

THE USE OF DRY PAPER INSULATION for telephone cables in Paris, France, to cheapen the cable investment, has made it necessary to adopt means to keep the paper dry. This is done by closing the ends of the lead-encased cables and forcing air, which has been passed over calcium chloride, through openings in the casing. This pressure is kept at about 45 lbs. per sq. in. and the air besides keeping the paper insulation perfectly dry acts as a safety device since a puncture is at once shown by a drop in the pressure gage.

◆

THE THIRD AVE. RY. CO., New York city, is about to adopt electricity on its 74 miles of track. At present 29 miles of this are operated by cable, the rest being horse-car lines. So far as possible the old cable conduit will be utilized, and the old 7-in. rails will be taken up and new rails weighing 104 lbs. per yd. will be laid. The new portions will employ the system which is proving so satisfactory on Madison Ave. Current will be supplied from a temporary plant until a large three-phase system can be installed. The power house for this will be at Kingsbridge, from which current will be transmitted to a number of transforming sub-stations.

◆

THE CONDUIT ELECTRIC SYSTEM is to be adopted by two more of the surface street railways of New York city. On July 20 cars will stop running on Sixth and Eighth Avenues and the roads will be turned over to the contractors. It is expected that by Sept. 15 both lines will be ready for operation by electricity.

◆

THE STREET RAILWAYS of Baltimore paid the city a total of $69,520 for the quarter ending June 30, 1897. This sum is 9% of the gross receipts of the company and goes to the park fund of the city.

◆

SEATS FOR ALL PASSENGERS, in elevated or surface street cars and stages within the limits of New York city, is the requirement of a resolution now before the Municipal Assembly and referred to the Law Committee. This ordinance, if passed, would require the transportation company to display a sign when the car is filled, and would impose a penalty of $25 for each offence for taking aboard more passengers than they could seat. No passenger need pay unless a seat were provided. Councilman Christman, in introducing this resolution, said that it was in response to popular demands; but if passed it will be very unpopular with those who have to wait on the sidewalk for a car having empty seats.

◆

A COMPARISON OF GROSS RECEIPTS for 1896 and 1897 of a number of American street railways is made in the "Street Railway Journal" for July, the figures for which were obtained from the 1898 edition of the "American Street Railway Investments." Of the 175 roads considered 26 had a gross income for 1897 of $1,000,000 or over; 19 earned between $500,000 and $1,000,000; 46 from $100,000 to $500,000; 51 from $50,000 to $100,000, and 33 from $25,000 to $50,000. Four systems, the Union Traction Co., Philadelphia; Manhattan Ry. Co., New York; the Metropolitan Street Ry. Co., New York, and the West End Street Ry. Co., Boston, have incomes ranging from $10,480,646 in the first case to $8,719,032 in the latter. The total income for these 175 companies having net earnings above $25,000 was $113,394,903, which was an increase of 1.9% over 1896.

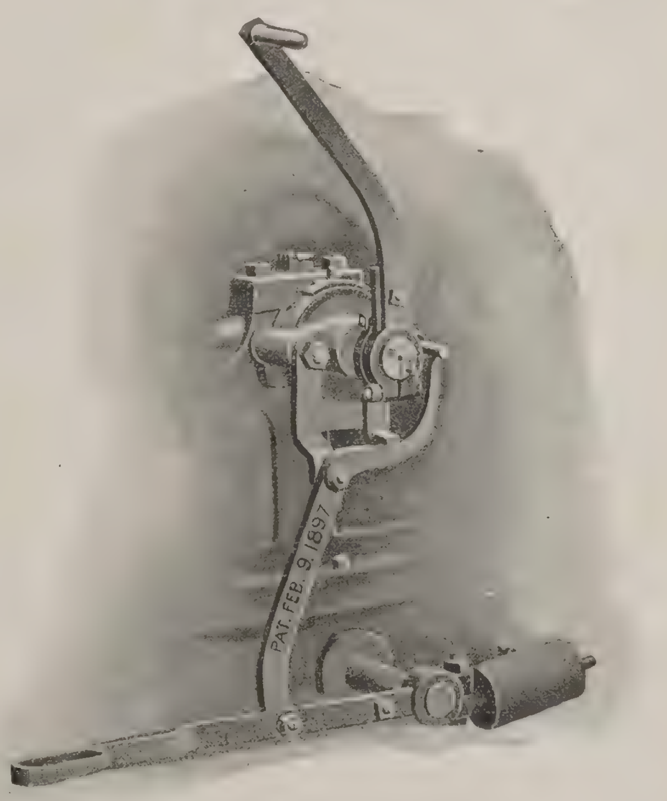

Fig. 2.—Lidgerwood Safety Lever Lock for Foot Brake of Boom Fall Drum of Derrick Engine.

◆

THE CONTRACTS FOR A MUNICIPAL ELECTRIC lighting plant which were awarded by the Board of Public Works of Grand Rapids, Michigan, on May 12, were vetoed by Mayor Perry on July 6. The reason given for this action is that sufficient consideration had not been given the question; that the engineers designing the plant were regarded by some as inexperienced; that the specifications were so worded that competition was impossible, and that it was estimated the cost would exceed the appropriation from $8,000 to $10,000.

THE COST OF ELECTRIC CURRENT in the case of several street railways which buy the "juice" to operate their lines, was given in a recent issue of the "American Electrician" as follows:

Location of road.	—No. of—		Miles of track.	Price paid.
	Motor cars.	Trailers.		
Georgia	24	9	18	$0.011 per K-W. hour.
Ohio	4	..	3½	$12.50 per mo. per car.
Ohio	5	At times	6	$2.10 per car day (18 hours).
Kentucky	10	"	6	(4) $2, (6) $1.50 per day
Maryland	5	"	..	$12.50 for 5 cars or less, $2 each addit'n'l car.
New York	10	"	6½	$0.015 per car-mile.
Texas	11	"	..	$0.015 per K-W. hour.
Texas	14	2	7½	$3.00 per car per day.
Massachusetts	..	..	..	$0.02125 per car-mile.
Massachusetts	..	..	..	$0.03 per car-mile.
New Hampshire	60	12	20½	$0.03 per K-W. hour.
Pennsylvania	14	..	8	$3.00 per car per day; $2.50 p'r car p'r day.
Pennsylvania	7	..	7	$2.75 per car per day (18 hours).
Vermont	3	..	..	$0.023 per car-mile.
Michigan	5	..	10½	$2 per 18 hrs. each car, $1.85 each ad't'l car.
Michigan	..	..	..	$2.50 per car per day.
Florida	2	..	3	$3.25 per car per day.
Alabama	4	..	7½	$3 per car per day (16 hours).
Nebraska	3	..	1½	$4 to $4.50 per car per day.
Tennessee	2	..	4	$3.00 per car per day (15 hours).

A BOILER EXPLOSION at the National Starch Mfg. Co., Buffalo, N. Y., on July 15, killed 7 persons and injured 35. Both the engineer and fireman were killed and the five tubular boilers were completely destroyed.

THE PRICE OF STEAM COAL IN THE EAST has greatly decreased in the past half dozen years. The following figures show the average New York selling price for the years given:

Year.	Bituminous coal.	Anthracite steam coal.
1892	$2.60	$2.07
1893	2.75	2.53
1894	2.65	2.18
1895	2.25	2.12
1896	2.50	1.93
1897	1.97	1.91
1898	1.75	1.82

THE NEW YORK, WYOMING & WESTERN RAILWAY Co. is a new company incorporated in Pennsylvania to carry anthracite coal from the Wyoming, Scranton, Wilkes-Barre and Lackawanna coal fields to tidewater at or near New York. The detailed plans are not yet made public, but it is reported that the company is to acquire the Lehigh & Hudson Railway, running from Belvidere, N. J., to the Poughkeepsie bridge over the Hudson, and thus gain an entrance into New England. It is to be a coal road only, passengers and other freight than coal being refused; and the rate is to be 60 cts. per ton to tidewater. The estimated cost of the road is $10,000,000, and the officers named are as follows: President, E. V. Sturges; Vice-President, L. A. Waters; Secretary, Thos. E. Jones; Treasurer, Thos. H. Watkins. All of the officers, including directors, are individual coal producers.

ANOTHER DECISION in favor of the Denver Union Water Co. has been rendered in the lower court in the suit of the city of Denver against the company. This time the court holds that the purity and pressure of the supply furnished by the company are up to the standards named in the contract. These standards were a chemical analysis of the supply furnished in 1889 and a hydrant "pressure equivalent, taking the elevation of the surface of the ground into account, to 115 lbs. at the hydrant in front of the Union depot in said city, provided: The city shall not be in default with said company upon any of its agreements." The company did not deny that the stipulated pressure had not been maintained, but urged that the introduction of a gravity system, in which the city acquiesced, and the substitution of larger distributing mains, gave a far more abundant and regular supply, affording better fire protection than could have been given at the contract pressure with the old system. The Judge accepted this view, although his language is a little at fault in using pressure as he did when he said the company "has and does supply a pressure fully as adequate for fire purposes as that provided for under the contract." The only testimony introduced regarding pressure showed that it was but 90 lbs. at the Union Station, instead of 115 lbs. We leave it to our readers to decide whether a contract provision calling definitely for 115 lbs. pressure is satisfied by 90 lbs., simply because the quantity of water available is greater at the lower than at the higher pressure? The previous decision of the court in this Denver case declared that the rates charged by the company were not in excess of the provision of the contract on this point. (See Engineering News, Feb. 24 and March 3, 1898, for editorial discussion.) It is said that the city will appeal the case.

BIDS FOR A NEW GRAVITY WATER SUPPLY for Jersey City will be received on Aug.18. The bids are to be made on the basis of first constructing works of sufficient capacity to deliver 50,000,000 gallons of water daily at the Bergen reservoirs, in Jersey City, at an elevation 210 ft. above mean high tide, through a single pipe line, but the drainage area must have a capacity of 70,000,000 gallons a day. If the city so orders at any time during the contract the capacity of the reservoirs and conduits must be increased to be able to supply 70,000,000 gallons and in case a masonry conduit or tunnel is provided for the original supply it must have a capacity of 70,000,000 gallons, but if this conduit is of steel it may be of 50,000,000 gallons capacity, to be supplemented, if so ordered, by a 30,000,000-gallon steel pipe. The city will buy water by the million gallons, with the option of purchasing the works at the end of 5, 10 or 15 years. Mr. Geo. T. Bouton is Clerk of the Street and Water Board.

A JOINT OUTLET SEWER is proposed in New Jersey for South Orange, Vailsburgh, Irvington, a portion of Newark, and possibly West Orange. It is stated that an engineer will be employed to make a report at an expense not to exceed $1,250. South Orange bought land for sewage disposal by intermittent filtration several years ago, but the land was located in another township, the people of which opposed the plant and secured general legislation prohibiting the location of a sewage disposal plant in any municipality of the state without first securing permission from the authorities of such municipality. The courts upheld the act. Newark has already constructed one outlet sewer jointly with East Orange, after the completion of which that township abandoned its sewage disposal works. The city of Orange, together with Montclair, Bloomfield and Glen Ridge, use a joint outlet sewer discharging into the Passaic River.

MUNICIPAL OWNERSHIP OF THE WATER-WORKS of Des Moines, Ia., is to be voted on at an election to be held Aug. 19. The proposition is to buy the plant of the Des Moines Water-Works Co. for $850,000, this price having been agreed upon by representatives of the bondholders, the city council and the Citizens' Association. If the purchase is made, a long controversy between the city and the company will be ended.

THE THEORY OF THE DIESEL OIL ENGINE, as given by Mr. Diesel, has been criticised in a paper read by E. Capitaine at a meeting of the Verein deutscher Ingenieure, at Frankfort, in April. He also attacks Diesel on the ground of priority of invention. Diesel's patent is dated February, 1892. In May, 1891, Capitaine took out two patents for an engine burning heavy oil injected into compressed air, and in the same year he built an engine, but its development was hindered by want of means. Diesel was fortunate, not only in obtaining pecuniary support, but in obtaining a pressure of 30 atmospheres in his engine, while Capitaine obtained only 15. The compression space in Diesel's engine in only half that in Capitaine's engine, and this, says Capitaine, constitutes the sole difference between the two motors. "The Engineer," which discusses Mr. Capitaine's paper at length, sums up the matter as follows:

> To sum up the matter, the novel points in the Diesel motor are perhaps not so many as its admirers claim for it. To start an explosion engine by compressed air is a method familiar to most engineers, as also to regulate its working by injecting varying quantities of combustible into compressed air, thus varying also the amount of air in excess. But it is scarcely correct to assert, as Capitaine does, that its sole claim to originality consists in diminishing the compresson space of an oil engine. We cannot go into the question of the commercial competition between these well-known inventors. But the fact must not be overlooked that Diesel has produced a practical engine, giving the highest heat efficiency and lowest consumption of combustible yet realized, namely, 0.52 lb. of oil per brake horse-power per hour at full power, with a 20-HP. engine; actual heat turned into work on the brake, 26%; and heat turned into indicated work, 34¾%.

THE KOCH HEAVY-OIL MOTOR-CARRIAGE, lately tested at the Paris motor-car exhibition, is thus described: The motor can be used equally well with crude petroleum, or with distillates like kerosene or naphtha. The two cylinders are placed end to end, with one explosion chamber in the center; the one explosion operating both cylinders. The piston rods are each connected by cranks and connecting rods to the fly-wheel shaft, which is fixed centrally below the cylinders, and the engine is thus exactly balanced. The motor runs at 600 revolutions, develops 6 brake HP. and weighs, with its fly-wheel, about 3½ cwt. Power is transmitted from the motor-shaft to a jack shaft by spur-wheels running in an oil-bath, and from the jack shaft to the rear wheels by the usual chain and sprocket gear. There are three forward speeds, of 5, 10 and 18 miles per hour, and one backward gear. This carriage, carrying four passengers, is said to be capable of mounting 10 to 12% grades with ease. The steering is done with the forward wheels, operated by a standard with a long, single handle.

A BUILDING ON CANTILEVERS, of peculiar design, has lately been erected in Birmingham, England, to utilize a valuable frontage that overhung the tunnel of the Great Western Ry. This tunnel was so near the surface as to forbid the use of girders spanning it, and the house could not be built upon the tunnel masonry. In this emergency Mr. R. Heaton, architect, devised a system of cantilevers to support a three-story warehouse with the front overhanging the tunnel 25 ft. at one end and 4 ft. at the other. The building is 44 ft. deep, and thus only 19 ft. rests upon the ground at the point of greatest overhang. The steel girders which support the building rest upon a pier, with its face 25 ft. from the frontage line; and as the overhang part of the girder in front is longer than the rear portion, a concrete counterweight is suspended from the rear member. The first cantilever, of the six used, supports 270 tons, and carries 160 tons of suspended load. The second cantilever carries the greatest load of 375 tons, and from this point the load decreases with the decrease of the overhang to 4 ft.

BOOK REVIEWS.

HISTORY AND DESCRIPTION OF THE WATER SUPPLY OF BROOKLYN.—Prepared and Printed by Order of the **Commissioner of City Works. I. M. de Varona,** Engineer of Water Supply. Cloth; 12 × 15 ins.; pp. 306, and 81 tables, unpaged; 104 plates, some folding. City Document.

This very handsome volume contains a vast amount of useful and interesting information regarding the water supply of the former city of Brooklyn, now a part of the Greater New York. It is, of course, impracticable to enumerate in detail the contents of the volume, as it includes, as the title states, a "History and Description of the Water Supply of Brooklyn." Many tables, reproductions of photographs, maps, diagrams and other drawings contribute their part to make up a book which does honor to those who prepared and published it, as well as to the city for which it was designed.

The Brooklyn water-works possesses many interesting features. One of these is the large number of driven-well stations, intended originally only as temporary means of supplementing the surface supplies.

The volume contains biographical sketches of the various chief engineers of the works, up to but not including Mr. de Varona, and a good portrait of Mr. Jas. P. Kirkwood, Chief Engineer of the Brooklyn works during their construction. The various rules and regulations of the works are given, including those for the sanitary protection of the water supply. One of the most interesting of the many tables in the book is one giving a detailed statement of the yearly receipts and expenditures of the works. The total cost of construction up to the close of 1895 was $22,102,701 Other valuable tables are rainfall records for Brooklyn and vicinity, and detailed statistics regarding the various pumping plants and their operation. The consumption of water was 12 gallons per capita in 1860; 47 in 1870; 54 in 1880; 67 in 1890; and 75 in 1895. The first figure should not be given much weight, as the works were completed in 1859.

THEORIES DE L'ELECTROLYSE.—**Par Ad. Minet,** Ingenieur-Chimiste, Directeur du Journal L'Electrochimie. Paris: Masson et Cie. Paper; 7½ × 4½ ins.; pp. 175. One of the series of "Encyclopedie Scientifique des Aide-Memoire."

The author takes up the history of electrolysis from 1772, when Paets, of Troostwyk, discovered that he was able to decompose water by means of the current furnished by the great static electric machine at Harlem. But investigators were then studying the mechanical rather than the chemical effects of apparatus of this kind, and Paets's discovery of the electrolytic phenomenon was regarded as of secondary importance. Faraday, later, laid down the broad law, and the investigations of Weber, Mascart, Kohlrausch, Lord Rayleigh and Sedgewick definitely fixed the quantity of electricity necessary for the decomposition of an amount of electrolyte equal to its equivalent expressed in grammes, and according to Becquerel's law. The author broadly defines electrolysis as the phenomenon of decomposition engendered by the passage of an electric current through certain chemical compounds of determined function; and all substances susceptible of being thus decomposed by the current are known as electrolytes. The latter must fill two conditions; they must be conductors of electricity and be sufficiently fluid. The general laws and physical theory of this phenomenon are then discussed at length. The second part deals with the constitution of electrolytes, and the modern chemical theories as here applied; and the next division discusses the electrolytic constants, methods of measuring the resistance and conductivity of electrolytes; effect of saline mixtures; and the electrolytic transport of the ions. The work closes with a very full biography and an excellent table of contents.

ANNUAL MEETING OF THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The 15th general meeting of the Institute was called to order in the Bee Building, Omaha, Neb., on the morning of June 27 by Mr. A. E. Kenneally, the president. Mr. W. W. Bingham, President of the City Council; Mr. G. W. Wattles, President of the Exposition; Mr. E. Rosewater and Col. J. J. Dickey were introduced and made appropriate remarks, to which the president replied and then read his address. The growth of the electrical industry during the last 15 years was traced, and the progress in the industry which, in 1884, involved only $1,000,000, and now over $900,000,000 was interestingly outlined.

Mr. C. P. Steinmetz then read a paper entitled "Dielectric Strength of Air," which was a description of a series of tests of striking distances in air with different forms of terminals and a mathematical discussion of the data obtained. In conclusion Mr. Steinmetz said:

1. At constant voltage and constant wave shape, that is constant ratio between maximum and effective E. M. F., the striking distance is a constant, especially between sharp points, where the tests have been repeated over and over again, and independent of the atmospheric condition, the frequency, etc., to such an extent that the striking distance between needle points offers the most reliable means to determine very high voltages.
2. No physical law has been found to represent satisfactorily all the observations. Some point to the existence of constant dielectric strength of air, analogous to the tensile strength of mechanics. Others point to the existence of a spurious counter E. M. F. of the spark or transition resistance from electrode to air.
3. Constant dielectric strength. Cylinders of 1.11-in. diameter give an average disruptive strength of air of 60 kilovolts per in. Cylinders of .315-in. diameter, an average dielectric strength of 77. Spheres at very small distance point toward the latter value. As a disturbing factor in this case, enters the electrostatic brush discharge, which by a partial breakdown of the air surrounding the electrodes changes and increases the size and decreases the distance of the effective terminals.
4. Counter E. M. F. of the sparks. The tests with sharp points give 22 kilovolts, or 11 kilovolts for a single transition from terminal to air. Spheres give curves pointing to a similar phenomenon. Electric conductors inserted at right angles into or parallel with the discharge, point to the existence of a counter E. M. F. of the same magnitude. The beginning of the electrostatic brush discharge is at a potential of this magnitude also.
5. Potentials of 160,000 volts effective and even up to 170,000 volts have been experimented with. They are probably the highest voltages ever reached by man at ordinary frequencies with alternating currents of considerable power.

Mr. John W. Howell read a paper entitled "Two-Wire Distributing Systems and Lamps at 220 to 240 volts." This paper described the saving in copper resulting from the use of a two-wire system in connection with the higher voltage lamps and recounted some of the troubles encountered in the use of 220-volt. lamps. The statement was made that the future of 200-240-volt systems depended upon the development of a more economical lamp, as all other elements of the system were already provided or could be produced with the means or knowledge now at our command. The third paper, "A Capillary Electrometer for Electrical Measurements," by Mr. Charles F. Burgess, was read by the Secretary. Mr. Burgess' instrument depends upon the change of surface tension of two liquids (preferably mercury and dilute sulphuric acid), which are in contact in a capillary tube. The meniscus which is found at the separating surface moves upon the application of a potential to the liquids. This movement can be measured, as can also the potential producing it, and the instrument is in this way calibrated. The methods of measuring insulation and electromotive force were described.

The afternoon and evening were given up to visits to the Grant Smelting Works and the Union Pacific Shops and the night illumination of the Exposition Grounds.

The morning session of June 28 was devoted to papers, the first of which, entitled "A Modern Central Station," was read by Mr. Geo. A. Damon (Eng. News, July 14, 1898). Dr. Francis B. Crocker followed, reading the Preliminary Report of Committee on Standardization, a committee appointed some time ago to draw up a code to govern the construction of certain electrical apparatus. Such quantities as efficiency, rise of temperature, insulation, regulation, variation and pulsation, rating, classification of voltages and frequencies, etc., are included in this report. The report is a tentative one, and was presented to give members an opportunity to criticize and submit suggestions. The afternoon and evening were devoted to sight-seeing.

The first paper the next morning, June 29, was by Mr. Ernest J. Berg, on "Transmission and Distribution of Power for Railway Service." This was a somewhat mathematical discussion of alternating current systems for railway work with especial reference to generation and transmission, and the available means of regulation from the generating station.

The next paper presented, "Some Phases of the Rapid Transit Problem," by Mr. Albert Armstrong, dealt with train acceleration, train energy and breaking. A number of curves plotted from certain average assumptions were included with accompanying explanations. Mr. D. C. Jackson's paper "The Commutated Curve of a Composite Wound Alternator" was read by title.

The morning of the last day, June 30, was devoted to the following papers: "The Graphic Treatment of Alternating Currents in Branch Circuits," Henry T. Eddy.; "Air Core Distribution," Prof. W. E. Goldsborough, and "High Voltage Power Transmission," Chas F. Scott.

The attendance at the convention was small, as was to be expected by reason of the long distance from the electrical centers of the East. The papers are published in full in the May number of the Society's "Proceedings," which can be obtained from the Secretary, Mr. R. W. Pope, 26 Cortlandt St., New York city.

SUMMER MEETING OF THE AMERICAN SOCIETY OF HEATING AND VENTILATING ENGINEERS.

The first summer meeting of this society was held at the Hotel Irvington, Atlantic City, N. J., July 15. Two sessions were held, one beginning at 2.50 p. m. and the other at 8 o'clock in the evening. The attendance was disappointingly small.

The afternoon session was called to order by President A. R. Wolff, with few appropriate introductory remarks, in which he explained that the summer meeting was intended to be largely of a social nature.

The first paper, "Some Accepted Tests of Ventilation—Are They Reliable?" was read by the author, Mr. T. C. Northcutt. We condense it as follows:

Most of the methods and instruments by which we measure the results of ventilation have come into use within a generation. They are comparatively new and to some extent defective. We are not to abandon methods of testing because they are defective until we have found other methods that are less defective, but I think it important to recognize their shortcomings.

Carbonic Acid Gas Tests.—To discover the degree of impurity of air in occupied rooms it is usual to determine the proportion of carbonic acid gas. The excess of this gas over that which is normal to outside air in a clean locality is taken as showing the degree of impurity. This test is only approximate.

Carbonic acid gas is not the only, nor the worst, poison discharged into the air of an occupied room. An eminent authority states that "a man of average weight throws off through the skin during 24 hours about 18 ozs. of water, 300 grs. of solid matter and 400 grs. of carbonic acid gas." This is nearly 3 lbs. of poisonous matter discharged into the surrounding air by every vigorous adult in each 24 hours. But less than one-third of this is carbonic acid gas. It is well known that the solid matter of excretion in an occupied room is a most deadly poison. We have no accurate means of testing its volume, except by laborious processes in the laboratory not available or practicable for general use. Yet the test for carbonic acid gas in vitiated air is, under carefully guarded circumstances, approximately correct, and, if rightly used, is of great value. This is true because an excess of carbonic acid gas is ordinarily a close companion of all other forms of crowd poison. Its presence indicates the presence of its ally.

Lime Water Test.—This test aims to determine the presence of carbonic acid gas. It does not, except by inference, determine the presence of other forms of crowd poison. It depends upon the fact that carbonic acid gas passed into and through lime water will precipitate the lime in the water, making the water which was at first absolutely clear to be more or less clouded and dense with chalky matter. The amount of carbonic acid gas discharged through the water determines the degree of density.

With the Wolpert Air Tester, for example, you are to determine the volume of carbonic acid gas that is passed through the water by the number of times you have discharged a bulb full of contaminated air through the lime water before the water becomes so dense that a black spot at the bottom is obscured. It is evident that the experimenter may, or may not, exhaust the bulb, or air pump, to the last degree at each filling. He may, or may not, fill the bulb from that limited area of air immediately surrounding his own head, and into which he has just that instant discharged the contents of his own heated lungs. This does not impeach the honesty of the operator. It is simply a question of his knowledge, his skill and precision.

Again, to determine when the black spot can no longer be seen through the lime water is a question of vision, and everyone who has made use of this test knows how difficult it is to be quite sure when the vanishing point is reached. The various lime water tests in popular use are thus defective. But this test is not without great value, and we must continue to use it until something better is known. We should look with some degree of skepticism, however, upon any such test made by the inexperienced.

The Anemometer.—The anemometer is the most useful instrument in determining the results of ventilation. I mean a good anemometer. I have seen some that are no better than an old-fashioned fanning mill. It should be carefully kept in adjustment. Ventilation is, more than anything else, dilution, and so after all the best test of adequate ventilation is the anemometer test. And yet the anemometer, even if a good one, in the hands of an inexperienced or injudicious person, is an unscrupulous liar.

We must continue to use tests which are recognized as in some measure defective. We continue to use them because they are the best known. We must be careful, however, to make these tests with a full knowledge of their shortcomings, and a disposition to carefully watch for every affecting circumstance. In the meantime we will urge inventors to find better instruments for our purpose.

Mr. Jellett, in the discussion, said that his experience demonstrated the approximate nature of tests made with the anemometer. In one case where a delivery of 40,000 cu. ft. per minute was called for in the specifications, his test gave 41,000, while that made by the engineer in charge gave 47,000, and someone else might have obtained 37,000. In the case in question the flue velocities were found to vary considerably, owing to offsets in the flues, and the delivery was altered by the opening or closing of dampers in side flues. Attention was called to the fact that all 3-in. anemomenters seemed to have the same friction coefficient (30) and the reason for this was briefly discussed without arriving at any conclusion.

Mr. Henry C. Meyer, Jr., questioned the accuracy of the author's statement that the carbonic acid gas would rise, and the other exhaled material would settle. It was explained that the separation was only temporary and resulted from a difference of temperature, the CO_2 being hotter than the other products when exhaled.

The Secretary then read Mr. McClellan Davidson's paper, "The Use of Draft Regulators," which was intended to open a topical discussion.

This paper considered in a general way the question of draft regulators for domestic service, stating that any regulator to be of service must be simple, quick to respond to temperature changes, and thoroughly reliable, conditions not completely fulfilled by any regulator in the market as far as his experience went. The best system at present in use employed a thermostatic device, but it was a mistake to claim, as some manufacturers of regulators were doing, that one type was suitable for all purposes, and all systems of heating. With steam heaters the changes were apt to be rapid compared with hot water systems. It was therefore necessary to employ special forms of regulators each suitable for a certain set of conditions.

Others stated that hot water regulators were slow to operate, all closing too slowly and opening too quickly. As an example of the uncertainty of automatic regulators, the case of the operating room of a hospital was mentioned. This room had a large skylight and the sun's passing under a cloud would cause a variation of the room temperature of 5°, notwithstanding the automatic regulator in use.

A paper on "Boiler Furnaces," by Mr. M. C. Huyett, of Detroit, Mich., was read by the secretary. The following is an abstract:

Boiler Furnaces for Steam Power Installations.

The Central High-School Building, Detroit, Mich., has been used two winters. The power plant has four horizontal tubular boilers, aggregating 428 HP. The furnaces were plain grates, hand fired. From September, 1896, to March 1, 1897, 1,093 tons of soft coal were burned, costing $2,892. From March 1 to the end of school term, 190 tons of soft coal were burned at a cost of $536.

The building is in a fine residence part of the city, and complaints of "smoke nuisance," and threats of suits were frequent. The use of anthracite coal was considered favorably and the consulting engineer for the board estimated that 1,000 tons would be required. Proposals were advertised for, and the lowest bid was $4.88 a ton. At the same time proposals were asked for Jackson Hill (Ohio) nut and slack. The lowest bid was $1.69, delivered in the building.

Mechanical furnaces were installed in August, 1897. From September, 1897, to March, 1898, 806 tons Jackson Hill nut and slack were burned at a cost of $1,362.14. The engineer then estimated that 150 tons would complete the school term, at a cost of $253.50. Total $1,615.64.

If the engineer's estimate for the incomplete part of the term proved to be correct, the economy in favor of the mechanical furnaces and cheap bituminous coal would be $1,811.

The known quantity is the two school terms to March 1—$2,891, $1,362 or $1,529 economy.

It is safe to assume that had anthracite been used 1,000 tons would have been required, and fuel cost have been $4,880.

There has not been a single complaint of smoke nuisance whilst burning the 1,000 tons of bituminous nut and slack coal. Almost continuously the chimney top has been absolutely smokeless.

When working a boiler at full duty rating of 100 sq. ft. of heating surface per horse-power with a mechanical furnace 3.16 lbs. Pocahontas R. M. was burned per HP. hour; 3.74 lbs. Jackson nut and slack was burned per HP. hour; 4.4 lbs. Hocking Valey slack was burned per HP. hour; 3.65 lbs. Belmore pea was burned per HP. hour; 4.1 lbs. Cherokee, Kan., slack was burned per HP. hour.

I have test data with slack coal, hand fired, and like coal mechanically fired. The economy favored the mechanical furnace 20%.

Mechanical furnaces require slack or nut and slack, or nut sizes of coal, and with only reasonable attention for some types, and no attention for another type, will consume such sizes of bituminous coal with stack conditions ranging from some smoke—but no smoke nuisance—to absolutely smokeless almost continuously. At no time will chimney gas escape be opaque.

Bituminous slack and screenings coal can be burned so satisfactorily as to not cause a nuisance to occupants of adjoining properties, and with such economy as to fully justify the large money investment required for a modern mechanical furnace plant.

Mr. A. Harvey mentioned the case of the Michigan Central R. R. station at Detroit, Mich., in support of the automatic stoker as against hand firing. In this plant, 1,200 tons of hard coal were formerly required, while with mechanical stoking 1,000 tons of slack were used, thus effecting a saving of about $5,000 a year.

Mr. Jellett called attention to the fact that the economy resulting from the use of mechanical stokers depended upon the locality in which they were employed, the entire question hinging on the relative cost of hard and soft coal, and while stokers made such a fine showing in Detroit, where hard coal cost so much, the saving would be greatly reduced in a place like Philadelphia, where hard coal is cheap.

In opening the evening session, the President announced the following as members of a committee to collect data concerning school-house heating and ventilation in their respective cities: A. E. Kenrick, Boston; Geo. I. Rockwood, Worcester; Ernest Glantzlong, Springfield; Mr. Strangerland, New York; Wm. M. Mackay, Newark; T. C. Northcutt, Syracuse, Rochester, Elmira and Buffalo; H. R. Harvey, Detroit; John Gormly, Philadelphia; B. H. Carpenter, Wilkes Barre, Scranton; Henry Adams, Baltimore and Washington; J. A. Larydon, Pittsburg; H. D. Crane, Cincinnati; D. M. Quay, Chicago; Prof. J. H. Kinealy, St. Louis; Charles T. Tay, San Francisco; David N. Nesbitt, London, England, and A. B. Reck, Copenhagen, Denmark.

The first paper of the evening, "A Suggestion for Determining the Heating Surface of Indirect Radiators," by Mr. H. Eisert, was read by title only, owing to its technical nature, which would require some personal explanation by the author. It will be published in full in the annual proceedings.

A topical discussion, "What is the Best Means of Advancing the Interests of Our Society?" was taken up and considerable time was devoted to considering the objects of the Society, the classes of engineers eligible to membership, and the number of such engineers. Entrance requirements were discussed and the resulting feeling was that everything considered, for a young Society with a high standard for admission, the American Society of Heating and Ventilating Engineers was holding its own.

The fourth topic, "The Consulting Heating and Ventilating Engineer—His Relation to Owner and Contractor," was discussed by Mr. Jellett who quoted from a paper on the same subject read by Mr. Wm. H. Bryan before the meeting of the American Society of Mechanical Engineers, held at Niagara Falls in June (Eng. News, June 2, 1898). He stated that the consulting engineer bore the same relation to the owner that the architect did, and at the same time, like the architect, must have the confidence of the contractor. The duties of a consulting engineer were outlined, and the common practice of accepting bids in which it was quite certain the contractor had made some mistake, afterwards holding him to his contract and thereby making him lose, was condemned. Such action usually resulted in poor work somewhere which would eventually bring the cost up to what should have been allowed.

The consulting heating and ventilating engineer is a recent growth. In most cases he is qualified to do what is claimed by his title. There are, it is true, many equally competent engineers connected with manufacturing firms, but these from this business connection are not in a position to occupy a proper relation to the customer, and hence could not be called consulting engineers.

ANNUAL MEETING OF THE INTERNATIONAL MINING CONGRESS.

The first annual meeting of the Congress was held at Salt Lake City, Utah, on July 6, 7, 8 and 9.

This organization is a result of the gold mining convention which met a year ago in Denver, at which it was decided to extend the scope so as to include all mining and to adopt the more comprehensive name.

At the first session on Wednesday, July 6, there was a rather small attendance. Addresses of welcome were made by the governor of Utah and the mayor of Salt Lake City and were responded to by Col. B. F. Montgomery, of Colorado. The president of the Congress, ex-Gov. Bradford T. Prince, of New Mexico, gave an able address, in which he pointed out that by extending the latitude of the convention to include all mining interests, $750,000,000 in annual product was now represented instead of only $60,000,000 for gold alone.

It was also pointed out that of the five principal metals—gold, silver, copper, lead and iron—the United States today produces more than any other country. Her copper production is greater than that of all the rest of the world. At the afternoon session J. W. Neill, mining engineer of Salt Lake City, read a paper on "Advances in Methods of Concentration." At this session was presented the report of the committee on revision of the Federal mining laws, the most important matter brought before the Congress. The chairman, Chas. J. Moore, mining engineer, of Colorado, presented the majority report and made a strong speech in support of it.

The report was very voluminous, but the principal change recommended in the existing law was the entire annulment of the so-called "apex law" at present applied to lode claims.

By this law the owner of a mining claim is allowed extra lateral rights, that is, he has the right to go beyond the side lines of his claim in following the vein on which he has located. Mr. Moore said in part:

> In the year 1879, only seven years after the passage of the present mining law on May 10, 1872, the evils resulting from its operation had become so great that Congress appointed a public land commission, which investigated most thoroughly the causes of the troubles arising from the present law, and made an exhaustive report. This testimony before this commission showed great evils then existing; and they have grown worse during the 18 years since that commission's report.
>
> To eliminate the "apex-law" would be to return to the common law, which declares that the owner of any portion of the earth's surface is entitled to everything enclosed by vertical lines or planes reaching from his surface boundaries down to the center of the earth, but to nothing outside of them.
>
> By the abolition of the apex law we destroy at once the principal source of the most expensive, harassing and disastrous litigation in our Western States and Territories; but we would compensate those who think they should have possession of every vein throughout its entire depth when its apex is within the surface boundaries of their location, by doubling the size of the maximum location over that of the present law, making it 40 acres instead of 20 acres; and further by expanding the manner of discovery and permitting a location to be taken in any form, thus eliminating all difference between side lines and end lines. The apex law was a legacy from Spain, which we inherited when we acquired the Spanish colony of California, and all the Spanish-American countries except Bolivia have now abandoned it.

Another principle advocated in the report is that of entirely segregating as soon as possible any portion of the public domain upon which a discovery of precious or useful minerals may be made, by requiring the owner of a mining claim to patent his ground within five years from the date of location. Adverse claims are to be adjudicated at the time of location, the original survey of the latter to be now made an official act, and to serve without any subsequent survey as that upon which the patent shall ultimately issue.

In the proposed new law the tunnel-site feature is retained, but its provisions are limited to the ownership of veins not previously covered by surface locations, and are expanded to include the right of possession of the underground places on the beds of ancient rivers, such as are called in California "deep placers."

The discussion of the majority and minority reports of the committee was undertaken at the afternoon session on Thursday, July 7.

The two reports had been printed for distribution among the members, and the minority report was presented by Judge W. B. Heyburn, of Idaho, who made a vigorous speech in its support.

This report recommended the retention of the apex law and of practically the present system of laws, with the abolition of local rules.

The speaker asserted that the "square" claim law (vertical sides) had been in effect in British Columbia since 1891, but that they now desired to change back to the American system. He claimed that the recommendations of the majority report, if enacted into law, would work untold hardship on the prospector who was generally of humble means and who could never begin to comply with the seven notices required, and with the $50 preliminary deposit which the U. S. Surveyor-General required at the time of making the location. He gave examples of the location of certain claims that had laid the foundations of some of the greatest camps in the world, where the locators had barely enough money to pay the recorder's fees. The minority report recommended the establishment of a base line for every ledge as follows:

> The end lines of the first location made upon any ledge shall govern as to the direction of the end lines of all subsequent locations upon the same ledge.

In concluding, Judge Heyburn urged that, though there had arisen many difficult questions in the past in connection with our mining laws, that they had stood the test of a quarter of a century during which they had been interpreted at a cost of millions of dollars, and that it was unwise now to enact any new ones.

Prof. W. S. Keyes, geological expert of California, made an argument for the majority report. Among other things he said:

> I look upon the extra-lateral permission of the law as the chief vice of our present mining code. It has caused more heartaches, more law suits and more rascality and perjury than any dozen laws upon our statute books. On the authority of a former Surveyor-General of Nevada, Mr. S. H. Marlette, there was expended in litigation on the Comstock lode during the years of 1860-'65 inclusive, not less than $9,000,000—one-fifth of the total product of the mines, and, considerably more than was declared in dividends during the same time. Senator William Stewart estimates the cost of litigation carried on by the Chollar and Potosi mining companies, prior to 1866, at $1,300,000, and the expenses of the Ophir-Moscow war at nearly $800,000. The total costs of litigation in the Washoe district up to Jan. 1, 1896, he computes at $10,000,000. As a part of the litigation there sprang up a horde of greedy, conscienceless "standing witnesses," ready, for pay, to swear to anything. Dr. Raymond, in "The Mineral Industry," says: "The full development of the mineral resources of the West will never come to pass until the capital it requires is better protected by definiteness in title and boundaries of mining property. And that cannot be done, in my judgment, by any amendment of the present law, which shall leave in it the present abnormal, irregular, indefinable, precarious, and mischievous extra-lateral right." It is bad enough to be obliged to take the usual mining chances, but when, in addition to this—to use the words of Chief Justice Beatty of California, long on the bench in Nevada—we have the certainty of a law suit, provided the mine proves to be of any value, the outlook for the legitimate miner and investor is far from encouraging.

Professor Keyes then answered the objection that the adoption of the "square" claim would tend to the monopolization of a district by asking why it was that all the other nations of the earth used the system; and why it was that the system was used in all the states to the east that produced the commercial metals.

Among the lawyers, he asserted that the giants at the bar were a unit on the question, and that the "Engineering and Mining Journal,' of 'New York, and the "Mining and Scientific Press," of San Francisco, were both enthusiastically in favor of reform. In closing, he asserted that under the square or surface location no disputes could arise except such as could be determined by a competent surveyor.

The discussion of the reports was not concluded at this session, and it went over until Friday morning, July 8. It was evident that neither report could be approved, and ex-Congressman C. E. Allen, of Utah, offered a resolution as a substitute for both, which was adopted. This simply stated that it is the sense of the Congress that the mineral laws should be so amended as to do away with extra-lateral rights in mining claims, and instructed the President and Secretary to forward to the proper committees and officers at Washington, when Congress convenes in December, copies of the resolution. The main fight against any change in the laws was made by the prospectors.

At the Thursday morning session, Manuel Elquera, secretary of the Peruvian Legation at Washington, and a mining engineer, read an interesting paper on "The Mineral Resources of Peru." Mr. Elquera described the geographical situation and topography of Peru, and explained that of the vast mineral wealth of the country but little is really known. He had traveled a great deal in Peru in the practice of his profession and had journeyed for days at a time through regions where the earth at any place could be taken and washed, and would show particles of gold.

This paper was followed by one entitled "Some Remarks on the Cyanide Process," by Louis Fade, chief chemist and director of the Raessler & Hasdecker Chemical Co., of New York. Among other things the speaker said:

> So-called coarse gold is acted on by cyanide so very slowly that the process is applicable only to ores which contain the metal in a very finely divided state. The selective action of a dilute cyanide solution on gold ores in preference to the sulphides of base metals with which they may be associated, is so wonderful that, from a chemical point of view, we may say that it is possible to extract the gold from all low-grade ores by means of cyanide, with the exception of ores containing copper, zinc and antimony combinations. In these cases the treatment becomes difficult, if not impossible.
>
> On first thought one is inclined to believe that the finer the ore is crushed the better it is for leaching purposes, but this is very often a wrong conclusion. It may be all right for very hard silicious ore, but not for an ore containing, for instance, alumina and magnesia, which are very apt to form slimes when coming in contact with the cyanide solution, and thus render the ore impenetrable. A very good example is the experience of the now world-renowned Mercur mine in Utah. Some six or seven years ago when the process was being developed at the plant of this mine—which, by the way, was the first cyanide extraction plant in this country for the treatment of ore—the managers were advised to grind the ore to about 600-mesh in order to attain the highest possible extraction. The result was the saving of only about 40% of the assay value of the ore. After many attempts and experiments to solve this perplexing problem, it was decided not to crush the ore so fine, on account of its porous nature and its considerable percentage of talc and alumina, which latter rendered the ore difficult of peretration by the cyanide solution. The result was that the coarser the ore was crushed the higher the extraction became, and now it is found that the highest extraction—about 85%—is obtained when the ore is crushed to about ¼-in. cubes.

At Friday morning's session, a paper on the mineral resources of Venezuela was read by Francisco Yanes of that country. Señor Yanes gave an interesting topographical description of that country. He said that notwithstanding mining was still in its incipiency there were 226 mines which furnish 42 different metals. Attention wos called to the rich copper mines of Aroa and El Callao, which have proved astonishingly productive. The richest gold-bearing region is that of Guiana, where the fabulous land of "El Dorado" was located, which attracted so many adventurers to the coast of Guiana in the fifteenth century. There are 62 gold mines in Venezuela, all of which are high-class producers. There are also coal and asphalt mines and petroleum deposits, which have been worked at a profit.

Mr. Yanes was followed by T. W. Gibson, Secretary of the Bureau of Mines and Mining of Ontario, Canada, who, took occasion to preface his talk on the mineral resources of Ontario, by referring most feelingly to the sympathy of Canada for the United States in the present war, and to the close relationship between the two countries.

At the afternoon session on Friday, a paper entitled "Official Geology and its Relation to the Mining Industry," prepared by H. H. Stoeck, editor of "Mines and Minerals," of Scranton, Pa., was read by Prof. Arthur Lakes, of Colorado. The writer told of the first established geological survey—that of North Carolina—begun in 1823, from which the idea developed in different states. The Association of American Geologists was formed in 1840. For years in different states the surveys dragged on, often crippled for want of funds, until after the Civil War. Then came a revival of geological activity until work along this line is done in nearly every state of the Union.

A paper on "Mine Legislation and Mine Inspection in the Anthracite Coal Region of Pennsylvania," was then read by Mr. G. M. Williams, of Pennsylvania.

The speaker told of the beginning of all mine inspection in this country at the anthracite mines; of the opposition of the mine owners at first, and how much benefit it had caused, not only in saving of life and limb, but in the more vigorous health and increased capacity for work of the miners.

At this session Milwaukee was chosen as the place for the next annual meeting, getting about 70% of the vote cast, and Sept. 7 to 10 inclusive, 1899, was fixed as the time.

Mr. Richard H. Terhune, superintendent of the Hanauer smelter, near Salt Lake, read a paper on "Recent Advances in Silver-Lead Smelting," in which he gave the results of numerous experiments he had made.

At Saturday's session a resolution, offered by Prof. S. B. Christy, of California, was adopted, which recommended a liberal increase in appropriations for carrying on the U. S. Geological Survey, and also the co-operation of surveys now carried on by the states independent of the national survey. A vote of thanks to Director Walcott and his assistants was included. A resolution petitioning Congress for the creation of a Department of Mines and Mining, was also passed.

It was decided to establish a headquarters for the Congress at Salt Lake for the coming year, until it becomes time to remove them to Milwaukee to begin the preliminary work for next year. Mr. W. D. Johnson, of Salt Lake, the Secretary-elect, is to be in charge. Col. B. F. Montgomery, of Cripple Creek, Colo., was chosen President for the ensuring year.

The sessions were pleasant and fairly harmonious, notwithstanding the hot weather, which deterred many from sitting through them when there were more attractive resorts outside and at the lake. There were 28 states and 2 foreign countries with delegations in attendance. The greatest attendance at any one time was about 130.

A mineral exhibit was made at a hall near by, at which were shown some of the choicest products of some of the principal mines of Utah, and also some mining machinery.

On Saturday, an excursion was run to Bingham to inspect the Highland Bay (principally copper) mine and others. On Sunday excursions were run to Park City, to Tintic and to Mercur. At the latter place they had the rare privilege of going through the great Golden Gate cyanide mill, illustrated in Engineering News of May 19, 1898.

ENGINEERING NEWS
AND
AMERICAN RAILWAY JOURNAL.

VOL. XL. No. 4.

TABLE OF CONTENTS.

ENGINEERING NEWS OF THE WEEK 47-64
- Ten-Wheel Passenger Locomotives; Grand Trunk Ry. (illustrated) 50
- New Ship Canal Entrance to Harbor of Duluth, Minn. (with two-page plate) 50
- A Test of the Hardness of Cast Iron 51
- A New Type of High Potential Insulator (illustrated) 51
- The Cost of Boiler-Room Labor 51
- A New Continuous Recording or Integrating Engine Indicator (illustrated) 52
- The Engineer as a Useful Member of Society 53
- Experiments Upon the Durability of Different Metal Coatings Immersed in Sea Water 54
- The Calhoun Placer Mining Machine (illustrated) 54
- Legal Decisions of Interest to Engineers 55
- Weather Report for June 55
- A Year's Progress in Engineering 59
- Comparison of Recent Specifications for Fineness and Tensile Strength of Cements 61
- A Gasoline Hoisting Engine (illustrated) 62
- Rock-Filled Dams in California (illustrated) 62
- Book Reviews 64

EDITORIAL NOTES 56
- Comments of "The Engineer" on the Naval Battle at Santiago—The Falling Off in the New York Canal Traffic—A Test of an Air Cushion at the Bottom of an Elevator Shaft.

EDITORIAL:
- The Value of High Short-Time Tensile Strength Tests for Hydraulic Cements 57

LETTERS TO THE EDITOR 58
- The Patents on the Diesel Motor—Frog Angles and Crossing Frogs (illustrated)—The Report on the Condition of the Paints on the 155th St. Viaduct, New York city—Gould's "Arithmetic of the Steam Engine"—Notes and Queries.

THE SPEED PROPOSED FOR THE NEW BATTLEships has been modified by the Navy Department in a notice to shipbuilders dated July 26 as follows:

> The Department will in awarding contracts for the construction of battleships Nos. 10, 11 and 12, under its advertisement of June 7, give preference, other things being equal, to such bids as offer to guarantee the highest rate of speed and greatest coal endurance, the total weights of engines, boilers and coal, and the spaces allowed therefor, to remain as now fixed by the circular defining the chief characteristics of said vessels, and the Department plans and specifications and the vessels to have a steaming radius of not less than 5,432 knots at a speed of 10 knots per hour.

The original circular referred to specified the weight of coal to be carried as 1,200 tons; the weight of engines, boilers and all machinery in the engineer's department at 1,130 tons; the normal displacement at 11,500 tons, with a length over all of 368 ft., and a beam at the water line of 72 ft. Cylindrical single-ended boilers and four-cylinder triple-expansion engines were also specified.

BIDS FOR THE TORPEDO-BOATS AND TORPEDO-boat destroyers, which shipbuilders are now preparing, are not to be opened until Aug. 16, the date having been postponed to give some firms on the Pacific coast more time to prepare their proposals. It is said that thus far there have been comparatively few inquiries for the plans and specifications for these vessels. The high grade of workmanship and material which the government requires has caused several of the contractors to lose on the vessels of this type already built.

THE BRITISH NAVY is to be increased by six new battleships and twelve torpedo-boat destroyers, according to the statement of the First Lord of the Admiralty, Geo. J. Goschen, on July 22. The original naval programme provided for only two additional battleships to be begun this year; but the number was increased on account of information that Russia proposed to build six battleships this year. It is now reported, however, that Russia has greatly reduced its contemplated expenditure for the enlargement of its navy.

THE CONTRACT FOR TRANSPORTING THE SANTIago prisoners back to Spain was awarded by the government to the Campania Transatlantica, at a rate of $55 for officers and $20 for enlisted men. It will be seen that this rate is far below the bid made by a combination of the principal transatlantic steamship lines as given in this column last week. The United States also gains in that its responsibility from an international point of view, and the liability to complications, will be much less than if the prisoners were transported under a neutral flag.

THE "CRISTOBAL COLON" may yet be rescued and become a part of the United States Navy. If she is not it will not be for lack of energy on the part of Lieut. R. P. Hobson, Naval Constructor, U. S. N. The report of the expert of the Merritt Wrecking Co. who examined this vessel was that it would be impossible to float her; but the naval constructor was impressed with the possibility of righting the hull by the use of pneumatic caissons. He made a flying trip to Washington, secured the approval of the Navy Department, and the co-operation of the chief officers of the wrecking company, and a strong effort will be made to save this fine vessel before the hull is broken up by heavy seas.

THE U. S. PROTECTED CRUISER "CHICAGO," after about two years spent in alteration, is very nearly ready for service. The "Chicago" was authorized in 1883 and launched in 1885, and was one of the first of the "new navy." She was then equipped with a twin-screw compound overhead beam engine of 5,084 I. HP., giving her a trial speed of 15.3 knots. Her main battery included four 8-in., eight 6-in. and two 5-in. breech-loading rifles, with a secondary battery of nine 6-pdr. and four 1-pdr. rapid-fire, and two Hotchkiss and two Gatling guns. She was bark-rigged. The "Chicago" is now greatly changed. Her engines are of the twin-screw, slightly inclined triple-expansion type, with 9,000 I. HP., and these are intended to give her a speed of 18 knots. She is fitted with appliances for forced draft, on the closed fire-room system, with smokestacks 80 ft. high for natural draft. The advance in marine engine design, since the "Chicago" was launched, is made evident by the fact that her new engines, though almost twice the power of the original ones, weigh about 135 tons less. The vessel was originally provided with cylindrical externally fired boilers in brick settings, which were obsolete for naval use even when they were designed. These have been removed and in their place have been installed four single-ended Scotch boilers and six Babcock & Wilcox marine boilers. The former will be used for ordinary cruising and the latter only when it is desired to run at higher speeds. In her main battery the four 8-in. guns have been retained, but fourteen 5-in. rapid-fire guns have been substituted for the other breech-loading guns. The secondary battery now has seven 6-pdr. and two 1-pdr. rapid-fire guns, and two Colts' and one field gun. The masts of the ship have been replaced by military tops and her protective deck has been extended. The "Chicago" is 325 ft. long, 48 ft. 2 ins. extreme beam, 19 ft. mean draft, 4,500 tons displacement and 3,042 gross tonnage. She has a complement of 33 officers and 376 men.

THE CUBAN ORE MINES of the Spanish-American Iron Co., at Daiquiri, 19 miles east of Santiago, on whose steel pier and docks were landed most of Gen. Shafter's army, have several contracts on hand for the delivery of ore in Great Britain. For two years the mines were working under the protection of Spanish troops, but just before these troops retreated from Daiquiri they burned the roundhouse and shop of the company. These will be rebuilt and operations will be resumed at once.

THE IRON ORE PRODUCTIONS OF SPAIN in 1897 amounted to 7,468,000 tons, as compared with 6,762,000 tons in 1896. Of this product the Biscayan mines contributed 5,170,000 tons; Santander mined 800,000 tons; Murcia, 470,000 tons; Seville, 330,000 tons, and Almeria, 300,000 tons. Nearly all of this ore is exported, England taking 5,000,000 tons; Germany took 1,000,000 tons; France, 500,000; Belgium, 200,000 tons, and 60,000 tons went to the United States. Spain herself converts but a very small part of this ore; the Spanish production in 1897 only amounted to 297,000 tons of ingots, 63,000 tons of Siemens steel and 134,000 tons of structural iron.

A NEW STEEL PLANT is about to be built at Pullman, Ill., by a company of German capitalists, according to a press dispatch from Chicago. It is said that 20 acres of ground are to be covered with buildings, and that the plant will be one of the largest steel producing works in America. The news is important if true. It will require a very long purse to start a successful steel works. In order to compete with existing works it should have its own ore mines on Lake Superior, its own coal mines and coke ovens, and its own steam vessels and ore and coal docks, all of which means an expenditure of many millions of dollars.

TWO OF THE LARGEST STEEL PLATES ever made were rolled at the South Chicago Works of the Illinois Steel Co., on June 3. They were for the shells of consolidation locomotive boilers. The sheets before shearing measured 128 × 360 ins. and 130½ × 375 ins. Each was sheared into a plate 124 ins. wide, 220 ins. long on one side and 237 ins. on the other. The plate gaged at the four corners 0.577, 0.577, 0.574 and 0.576 ins., and at the ends near the middle 0.640 and 0.623 ins.

THE MOST SERIOUS RAILWAY ACCIDENT of the week occurred on July 22 at Dutch Flat, Cal., on the Southern Pacific R. R. The boiler of the locomotive of an eastbound train blew up while the train was standing at the station. The engineer, the fireman and a coal passer were killed and several others were slightly injured.

A WATER-WORKS TANK BURST at Beemer, Neb., on July 13, according to a press dispatch. It is stated that the hoops gave way at the riveted joints, and that the tank fell 25 ft.

A BROKEN SHAFT on the steamer "Friesland," of the Red Star Line, from Antwerp to New York, was repaired in mid-ocean, 1,450 miles from New York, on July 15, in such a manner as to allow the steamer to complete her voyage at seven knots, or about half her usual speed. The shaft was 16 ins. diameter, and a crack was discovered in it running around two-thirds of the circumference and 13 ins. through the shaft, the crack being open ½-in. at the widest point. The break was between the thrust block and the low-pressure crank. The temporary repair was made by a steel clamp and ½-in. wire wrapped tightly around the shaft. The wire was wound like thread on a spool by slowly turning the engine. The low-pressure cylinder was disconnected, and the vessel proceeded at reduced speed, arriving in port three days late.

AN ORDER FOR 500 COMPLETE STREET RAILWAY car equipments, including 1,000 25-HP. motors, 1,000 controllers and 500 trolleys, is reported to have been received by the Walker Co., Cleveland, O., through its Paris agency. The apparatus will be used in Italy, France and Germany.

BIDS FOR A STREET RAILWAY FRANCHISE between Elizabeth and Plainfield, N. J., will be received on Aug. 4 by the Freeholders of Union Co., N. J., at the Court House in Elizabeth. The Freeholders are acting under a law which provides for the widening, strengthening and grading of highways under the control of such bodies, and for the constructions of railways thereon. The estimated cost of widening the streets in question is about $350,000. Messrs. Frank J. Hubbard and J. F. Bauer, of Elizabeth, are the engineers for the county and Mr. S. Rusling Ryno is Clerk of the Freeholders.

ALL ELECTRIC WIRES IN NEW ORLEANS must be placed underground, in accordance with an ordinance passed several months ago. It is said that applications for space in the conduits have been filed by the Edison Electric Light Co., two telegraph and one telephone companies, all foreign corporations, but that no action towards compliance with the ordinance has yet been taken by companies operating under Louisiana charters.

BIDS FOR AN ELECTRIC LIGHTING PLANT are called for by the Shanghai, China, municipal council through F. S. Blackall, of Blackall & Baldwin, 39 and 41 Cortlandt St., New York city. The apparatus will include the two 100-K-W. alternators, direct connected to horizontal medium speed engines, water-tube boilers, switchboard, switches and instruments. Sealed proposals must be sent not later than Aug. 10 to the above address.

THE TRUSTEES OF THE SANITARY DISTRICT OF Chicago have vetoed the scheme of certain private parties to use the water from the drainage canal at its southern terminus for water-power development. They have taken the very proper ground that the water power which the canal will create is the property of the Sanitary District and if it is developed it should be developed for its benefit.

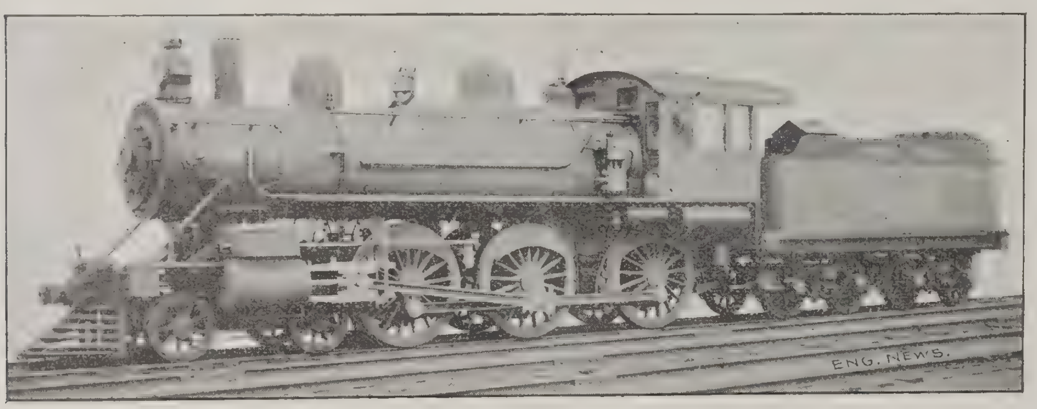
THE FRENCH SOCIETY OF CIVIL ENGINEERS, on June 10 and 11, celebrated the 50th anniversary of its foundation. There was a meeting at the Society House and speeches were made by M. Loreau, the President of the Society, and by the representatives of other societies, and a paper was read on the Alexander III. bridge by M. Alby, the engineer in charge. On June 11 the bridge of Alexander III. was visited, and in the afternoon there was a reception attended by the President of the French Republic and by M. Turrel, the Minister of Public Works, and at this meeting a number of orders were awarded to engineers by President Felix Faure. In the evening there was a brilliant reception with a great number of guests present. On June 13 the ceremonies terminated in a banquet of 500 covers at the Hotel Continental. This society was founded in 1848 and now has about 3,200 members.

THE SEPTIC TANK SYSTEM of sewage treatment was vigorously discussed at the recent meeting of the Incorporated Association of Municipal and County Engineers at Edinburgh, Scotland. Mr. Donald Cameron, City Surveyor of Exeter, and patentee of the system, sent a paper to the meeting which opened up the subject. The paper contained nothing new, but stated that the system was working most satisfactorily at Exeter, where about 65,000 gallons of sewage has been treated daily for 22 months with "no sign of requiring the removal of the deposit" from the tank. The majority of those who took part in the discussion, as reported in "The Surveyor," seemed to consider the system as still in an experimental stage. Several intimated that merely prefixing the word "bacterial" to variations of a well-known and long-practiced system of sewage treatment neither made the variation a new system of treatment nor increased the efficiency of the process. Some objections were urged, also, to the patenting of engineering inventions by engineers.

TEN-WHEEL PASSENGER LOCOMOTIVES; GRAND TRUNK RY.

The Grand Trunk Ry. has recently added to its equipment some large and powerful passenger locomotives of the ten-wheel type, which type of engine is coming to be very generally used for fast and heavy passenger service. A side view of the engine is more striking than the view shown in the accompanying cut, the long boiler being set very high, so that it is entirely above the wheels, which are 6 ft. in diameter. The appearance of the engine is somewhat peculiar, as it is painted black all over (including the boiler jacket), and this sombre color is relieved only by a very little bright work and lettering. All the lettering and striping is in aluminum leaf.

The boiler is of the extended wagon-top pattern, with a wide and shallow firebox dropped low at the front. The main steam dome and the special dome for the whistles and safety valves are mounted on the wagon top, the bell being on the throat sheet and the sandbox on the forward end of the barrel. All the rods are of I-section, and the side rods have solid ends. The engine is fitted with a 9½-in. Westinghouse air pump for the brakes and the air signal. The tender is mounted on two trucks with 43-in. wheels, which is much larger than is common in American practice, as shown in our issue of June 9. Six of these engines were built in April last by the Schenectady Locomotive Works, of Schenectady, N. Y., and we are indebted to the builders for the photograph from which the accompanying cut is prepared. The following is a list of the principal dimensions, given in our standard form:



TEN-WHEEL PASSENGER LOCOMOTIVE; GRAND TRUNK RY.
Schenectady Locomotive Works, Builders.

Ten-Wheel Passenger Locomotives; Grand Trunk Ry.

Running Gear.	
Driving wheels, (6) diameter	6 ft. 0 ins.
Truck wheels, (4) "	3 " 1 "
Tender wheels, (8) "	3 " 7 "
Driving-wheel centers, main	Cast steel.
Others	Steeled cast iron.
Truck and tender wheels	Steel tires.
Drvg. whl. tires secured	Shrinkage and retaining rings.
Engine truck	Swing center.
Journals, driving axles	9½ × 12 ins.
Wheelbase—Driving. 15 ft. 8 ins.; Truck	6 ft. 6 "
Total engine	26 " 11 "
Tender	16 " 6½ "
Engine and tender	53 " 9 "
Truck-pin to c. of lead. driv. wheel	8 " 0 "
Wheels having blind tires	Second pair.
Weight in Working Order.	
On driving wheels	124,990 lbs.
On truck wheels	41,000 "
Engine, total	165,190 "
Water in tank	37,500 "
Coal on tender	20,000 "
Weight of piston and rod	439 "
Weight of crosshead. .346 lbs.; Main rod	711¼"
Weight of front side rod	338 "
Back side rod	263 "
Cylinders.—(2)	20 × 26 ins.
Crosshead and guides	Alligator type.
Connecting rod, length between centers	10 ft. 8¼ ins.
Side rods	Solid ends.
Valve Gear.—Type	Stephenson link.
Ports, steam. .20 × 1⅝ ins.; Ports, exhaust	20 × 3 ins.
Bridges, width	5 "
Bridges, width	1⅜ "
Eccentrics, throw	5 "
Slide valves, balanced; max. travel	5½ "
" " ins. clearance. ⅛ in.; outs. lap.	1 "
" " lead in full forward gear (blind)	1-16 "
" " lead at 6 ins. cut-off, forward	¼ "
Boiler.—Type	Extended wagon top.
Diam. barrel, inside smallest ring	5 ft. 0 11-16 ins.
Dome, diameter	2 " 7½ "
Thickness, barrel plates	21-32 and ¾ in.
Smokebox tube-plate	¾ "
Horizontal seams	Sextuple riveted.
Circumferential seams	Double riveted.
Joints	Butt.
Height from rail to center line	8 ft. 9½ ins.
Length of smokebox, includ. extension	5 " 5 "
Does smokebox arrangement conform to M. M. Assoc rules?	Yes.
Injectors (2)	Hancock inspirator.
Working steam pressure	200 lbs.
Firebox.—Type	Wide, shallow; radial stays.
Length inside. .10 ft. 7 ins.; width inside	3 ft. 4⅛ ins.
Depth at front. . 6 " 4¾ " depth at back	5 " 5 "
Thickness, side plates	5-16 in.
" back plate	⅜ "
" crown plate	⅜ "
" tube plate	½ "
Crown stays . . . . . . .radial; Grate bars	rocking.
Is fire-brick arch used?	Yes.
Stay bolts (drilled), diameter	1 in.
" " pitch	about 3⅞ ins.
Water spaces front and back	4 "
" " sides	3½ "
Tubes.—(Iron), Number	291
Thickness . . . . .No. 12 W. G.; Pitch	2¾ ins.
Diameter, outside	2 "
Length over tube plates	15 ft. 0 "
Heating Surface and Grate Area.	
Heating surface, tubes (exterior area)	2,269.63 sq. ft.
" " firebox	185.85 " "
" " arch tubes	15.15 " "
" " total	2,470.63 " "
Grate area	33.44 " "
Miscellaneous.	
Exhaust nozzle (single), diameter	4¾, 5, 5¼ and 5½ ins.
" " distance below c. line of boiler	1½ "
Smokestack, diameter at top and base	16 "
" height above smokebox	3 ft. 1 in.
" height of top above rail	14 " 7¼ ins.
Capacity of tender tank	4,500 gallons.
Capacity of coal space	20,000 lbs.
Brake fittings, Westinghouse-American, outside equalized.	

* * *

NEW SHIP CANAL ENTRANCE TO THE HARBOR OF DULUTH, MINN.

(With two-page plate.)

The ship canal entrance to the harbor of Duluth, Minn., has been protected for some years past by two parallel piers, about 240 ft. apart and somewhat over 1,200 ft. in length. The increased size of the vessels now used on the lakes and the phenomenal growth of lake commerce have demanded the general improvement of this harbor and its entrance. Plans for the work were prepared some time ago under the supervision of Major Clinton B. Sears, Engineer Corps, U. S. A., in charge of government work on Lake Superior, and work is now in progress.

The harbor of Duluth now consists of the Duluth Canal, the Wisconsin entrance, Superior Bay, Allouez Bay, St. Louis Bay and St. Louis River to the limits of the cities of Duluth and Superior. These bays were once broad expanses of shallow water, averaging from 8 to 9 ft. in depth, except in the channel through them, and the original natural entrance was obstructed by shifting bars with 9 ft. of water. The works carried out by the U. S. government in past years have resulted in giving a good 16-ft. navigation through the natural or Wisconsin entrance; through the artificial Duluth Canal; over the Duluth Basin, of 104 acres; along and parallel to the dock lines of Duluth and Superior, and up the St. Louis River to New Duluth. The channels are well defined and are from 85 to 300 ft. in width. As before stated, however, commerce demanded deeper and wider channels, and a new project was authorized by Congress, on June 3, 1896, providing for the deepening of existing channels to 20 ft., the excavation of a new 20-ft. channel along Minnesota Point dock line, and for a general widening of channels and the creation of turning and anchorage basins 20 ft. deep. The project also includes the widening of the Duluth Canal, and replacing the piers of the Duluth Canal and Wisconsin entrance with substantial structures of timber and monolithic concrete. These plans demand an enormous amount of dredging, and contracts for dredging about 26,000,000 cu. yds. have been let, at an average of a trifle less than 8 cts. per cu. yd., to Williams, Green & Williams, of Duluth, Minn., and to Charles S. Barker, of Superior, Wis. This remarkably low price shows the economic value of the continuous contract system. The original estimate, based upon previous experience with intermittent appropriations, was 15 cts. per cu. yd. That the government is justified in making the expenditures necessary for the improvement of this port is shown by the fact that the lake commerce of Duluth and Superior amounted to over $112,000,000 in the navigation season of 1897; and since the United States took charge of this harbor this commerce has amounted to over $900,000,000.

The present descriptive matter and illustrations relate to the Duluth Canal entrance to Duluth harbor, and the plan given shows the location and general dimensions of the old and the new piers. This is probably the most interesting work included in the new project, from an engineering point of view, though somewhat similar work is to be performed at the Wisconsin entrance.

The contract has been let to King & Steele, for the construction of the substructure of the new south pier of the Duluth ship canal, through Minnesota Point, and a description of the work here proposed will answer practically for the whole improvement. We are indebted to the courtesy of Major Sears for the plans here used, and for the specifications relating to this work. These specifications show that the pier will consist of timber cribs, filled with stone and gravel, and resting upon piles cut off 22 ft. below low water datum. These cribs will be 24 and 36 ft. wide, with the tops extending to within one foot of datum, or low water; they will be built in sections of 50 and 100 ft. and the entire length of the south pier will be 1,722 ft. Resting upon these cribs will be a massive, concrete superstructure, generally 20 ft. wide at the base and extending to a height of 10 ft. above datum. The pierhead in the lake will be 36 ft. wide and 100 ft. long, and the channel face of the cribs will have an armor of 1-in. steel plate, to a depth of 7 ft. below the top, to protect the cribs from injury by vessels.

The character of the bottom material is clean sand, with a bed of gravel overlying the old Minnesota Point, about 13 ft. thick. A trench will first be dredged 26 ft. below datum and for the whole length of the pier, with a width sufficient to prevent any interference with the placing of the cribs. Piles, at least 9 ins. diameter at the small end, will be driven 4 ft. apart, on centers, longitudinally, and 4 and 5 ft. apart across the crib. Both the hammer and water-jet will be used in driving; and the final penetration will be 1 in. under the blow of a 2,000-lb. hammer falling 15 ft. The piles, when cut off, must be at least 17 ft. long, or penetrate the ground to a depth of 13 to 15 ft., thus making the pile about 43 ft. long before driving. A circular saw, mounted on a platform supported by the shoreward piles, will be employed in truly cutting off the piles 22 ft. below datum. The space between the heads of the piles will then be filled to within 6 ins. of the top of the piles with spawls and rock, not exceeding 1 cu. ft. in size, and gravel will be added to fill crevices and level the base to within a couple of inches of the tops of the piles. Protection piers, a pile dike and sheet piling along the trench slopes will be required for the protection of the work during its progress against lake storms, etc.

The pier cribs will be built as shown. The floor will be 8 ins. thick, laid close, with the under side flush; the timbers drift-bolted laterally, and alternate timbers secured by vertical machine bolts, 6 ft. long, passing up into the bulkheads. The channel side of the crib will be a double wall of 12 × 12-in. timbers; drift-bolted vertically, and machine-bolted horizontally. The rear side will be 12 ins. thick, and connecting these two walls will be transverse bulkheads, made of 10 × 12-in. timbers and, 4 ft. between centers, drift-bolted and with alternate sticks dovetailed into both walls. The cribs will be covered by 12 × 12-in. timbers near each side, and by 6 × 12-in. timbers for the remainder. Vertical posts, 10 × 10 ins., and 10 ft. 4 ins. long, will be bolted to the walls and bulkheads, as shown on the plan; and the timber to be used in these cribs will be white oak, for a certain number of courses near the top, and white pine or hemlock for the other parts. The pierhead cribs will be made stronger by the use of more oak, thicker bulkheads, double walls front and rear, and a double thickness of armor plate on the cutwater faces. All of these cribs are to be built in the harbor, towed into position and sunk by filling the pockets with rock and gravel in alternate 6-in. and 12-in. layers, commencing with the pierhead crib in the operation of sinking the piers and working towards the shore.

The pierhead crib, not shown here in detail, terminates in a cutwater having a central angle of 90° and sides about 25 ft. long, with the bulkheads arranged accordingly, and the whole crib strengthened throughout as outlined above. The cutwater will be faced with double 1-in. steel plates, for a height of 7 ft., riveted together and secured to the double timber wall by 1-in. machine-bolts with a counter sunk head in the plates. The under plate will return over the top of the upper timber, for a distance of 9 ins., and be bolted down by a 1-in. drift-bolt 24 ins. long and with counter-sunk head. The plates themselves will be generally about 8 ft. square, though these dimensions vary with positions.

At the ends of the several cribs the end bulkheads are 10 ins. back of the line of the floor, with four outside end-posts, as shown, bolted to the end bulkhead. Two sets of guide-stringers are built into the last two bulkheads, one set near the bottom and the other near the top of the crib. These 12 × 12-in. sticks project 9½ ins. beyond the line of the floor and are so spaced as to abut against the inside faces of the two middle guide posts on the opposing crib and serve as a guide in sinking. Before this space between two cribs is filled with ballast, a 4 × 6-in. timber, 19 ft. long, is run down to cover any space between the outside posts. This stick is secured in position by throwing in ballast against the bottom end and spiking the top. The pockets between the crib will then be completely filled with ballast. It is also specified that the last pocket in the crib is to be only half full of ballast before sinking to obviate any danger from the bulging of the ends before the cribs are in position.

The preliminary plans for the concrete superstructure, as designed by Major Sears, are shown herewith. This concrete work, with the exception of the footing blocks, will be built in place by depositing the concrete in molds forming sections of the full width of the pier and in lengths of 10 to 20 ft. The intention is to make each section as large as can be finished in one working day; and no layer of concrete will be allowed to set before the next is deposited and rammed. Four-sided molds will be used at first for alternate sections, and the intermediate sections will then be built with two-sided molds and a layer of tarred paper separating adjoining sections.

The footing blocks, 5 × 7 ft., and about 3 ft. high, will be molded on shore and then set close on the timber work to form the toe of the superstructure on each side of the crib. The only concrete deposited under water will thus be the limited space at the middle of the pier. American Portland cement will be used for these footing courses and natural cement for the remainder of the work. Beach gravel is abundant at the site of the work, and this will be used in the concrete and materially lessen the cost. A quantity of rubble stone will also be incorporated in the concrete, with suitable spaces between the stone, and the amount of concrete correspondingly lessened.

The steel plates on each crib are to be connected under water, after the cribs are sunk, by the use of straps 24 ins. wide, 8 ft. long and 1 in. thick. These plates will be secured in place by the "patch-bolts" shown. The strap will be punched and counter-sunk at the shop, and the drilling and tapping of the crib plates will be effected when they are in place by pneumatic tools operated by a diver. This arrangement will make a continuous line of well-connected 1-in. steel plates secured to the face of the cribs and reaching 8 ft. below low water datum. With a backing of 24 ins. of wall timber it is believed that these plates will efficiently protect the pier against all damage from ordinary collisions of vessels. In case two adjoining cribs do not exactly aline a special provision is made, as shown, for putting on the connecting straps.

A TEST OF THE HARDNESS OF CAST IRON.*

By Chas. A. Bauer, M. Am. Soc. M. E., Springfield, O.

Inasmuch as none of the previously known methods for determining the hardness of cast iron had proven to be practical, for a number of reasons, foremost among which was the impossibility of duplicating the results obtained, it became imperative that some method be devised that would be simple and yet reliable, and which would contain none of the objectionable features which are known to exist in other methods.

From the fact that a drill running at a uniform rate of speed and under a constant pressure, the number of revolutions which would be required to drill a given depth would be directly proportionate to the hardness of the material being tested, it was deemed expedient to formulate a method along these lines.

An ordinary drill press was equipped as follows: On the pinion shaft, which raises and lowers the spindle, is attached a disc 12 ins. in diameter, around the periphery of which is placed a light flexible wire cable, on the end of which is suspended a weight which maintains a constant pressure upon the drill. The standard drill is now placed in the chuck. The drill spindle has a revolution counter, and by means of magnets and an armature is controlled by the position of the drill in relation to the table. Adjustments are made so that the revolution counter is thrown into gear after the point of the drill is entirely embedded under the surface of the test piece, and out of gear when the spindle has descended from this point exactly one-half inch.

When the test is to be made the test bar is placed upon the table and the drill is brought down upon its surface; the feed lever is then unlatched. The drill is now rotated at a speed of 250 revolutions per minute, and the hole drilled. The revolution counter is electrically thrown into gear after the drill point is buried beneath the surface, and out of gear when the one-half inch from this point has been reached. The reading of the revolution counter now gives us the exact number of revolutions required to drill the one-half inch, and this we term the degrees of hardness. The more revolutions required, the harder the casting; slight variations in hardness being easily detected.

We have adopted, and would recommend as a standard, a ⅝-in. flat drill having an angle between its cutting edges of 120° and a clearance angle of 10°, running at a speed of about 250 revolutions per minute and having a constant pressure of 160 lbs.

The cutting angle may vary between 115° and 125° without affecting results, but the clearance angle should be 10°. The revolutions of the drill may vary between 240 and 260.

The pressure on the drill should be as near 160 pounds as possible in order to compare with results obtained elsewhere by this method, and should be determined while the drill is in motion. We have placed a small platform scale upon the drill table, then placed the test-piece on this scale and found the pressure to be 160 lbs. while making a test.

After the apparatus has been prepared and standardized, it is well to determine the hardness of a long test piece, which should then be put away and preserved as a standard. Any changes which may then take place can be entirely eliminated and results reduced to the standard by the formula,

$$\text{Degree of hardness} = \frac{Dr}{R},$$

in which D = the degrees of hardness of standard test piece; R = the number of revolutions of drill required to drill that piece under present condtions, and r = the number of revolutions obtained in drilling the piece, the hardness of which we wish to determine.

We make daily tests of our cast iron and mark each piece with its determined degree of hardness, and use any one of them to determine the change in the drill.

We have selected four test bars which represent four grades of hardness. Castings for our purpose should range between that determined for Bars Nos. 2 and 3; No. 1 would be considered too soft, while No. 4 would give us trouble in the machine shop and would surely bring in complaints. We repeated the hardness test on each bar, obtaining three results for each bar. We herewith submit results of these tests:

Bar.	Hardness.		
No. 1	130	128	129
No. 2	150	149	149
No. 3	170	168	167
No. 4	236	232	230

The greatest variation of results occurred in the drilling of the fourth bar, where it was less than 3%. We therefore believe that we have a reliable test and one that will prove of great practical value to all foundrymen.

A NEW TYPE OF HIGH POTENTIAL INSULATOR.

The insulator shown herewith represents the latest type of a form of insulator developed to meet the requirements of long distance electric transmission. In the early days of low tension and short distances the usual form of glass or porcelain insulators were found quite satisfactory. With increasing pressure it was found that leakage began to be a considerable and dangerous item. This was partially remedied by increasing the number of petticoats, thus increasing the distance over which leakage currents must pass to reach the supporting pin, and at the same time affording more certain drainage during rainy weather. The next difficulty was experienced with puncturing, that is, current piercing the insulation. The natural remedy was to increase the thickness and vary the material. The resulting type of insulator, commonly known as the "Locke," after its inventor, may be described as two insulators, one inside the other, held together by some cementing compound, such as sulphur. The insulator shown represents the latest type intended to obviate the difficulties mentioned. Like the "Locke," it consists of several pieces cemented together, the cementing material, however, being a glaze similar to that used in glazing porcelain ware. In this way the high insulating power of the glaze, which is considerably more than the semi-porous porcelain, is taken advantage of and, as will be seen in Figs. 1 and 2, six layers of glaze and two walls of glaze must be pierced before current can reach the iron pin R. Leakage from the petticoats to the pin is greatly reduced by making the pin also of porcelain. The method of manufacture of this insulator, as described in the patent (No. 601,195, March 22, 1898), is as follows:

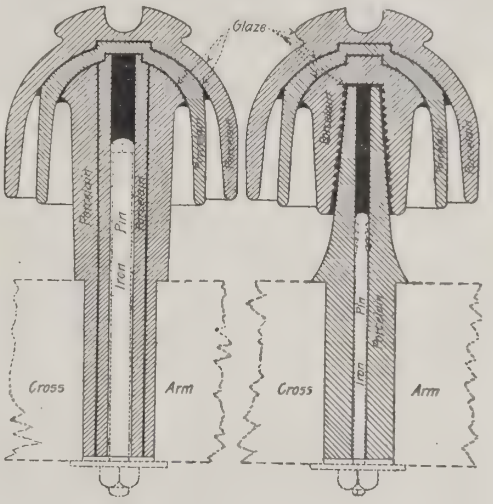

Fig. 1. Fig. 2.

THE BOCH HIGH POTENTIAL INSULATOR.
The R. Thomas & Sons Co., New York City.

The separately molded porcelain parts, after coming from the press, are dried separately, preferably in an oven or kiln, after the usual manner known as "biscuit firing"; when properly dried and ready for the vitrifying-kiln they are each coated with a glazing material, preferably all over, by dipping. The parts are then fitted together and turned upside down, i. e., drip edges up, forming a bowl into which the glazing liquid is poured until the space between the parts, represented by the black lines in the figure, is filled. The collection of parts is next carefully placed in the vitrifying-kiln and subjected to an intense heat, which melts the glaze and forms a solid, practically impenetrable layer or layers of the best kind of insulating material. The extra amount of glazing liquid prevents the formation of air spaces or cracks and fills all spaces resulting from a lack of correct fit or any shrinkage. Factory tests up to 60,000 volts have been made of this insulator with satisfactory results.

The insulators are manufactured, under patents granted to Mr. J. W. Boch, by the R. Thomas & Sons Co., 30 and 41 Cortlandt St., New York city.

THE COST OF BOILER ROOM LABOR.

A circular has been issued by the Mutual Boiler Insurance Co., 31 Milk St., Boston, Mass., for the information of its members, on "Cost of Boiler Room Labor." It is reprinted from a circular issued by the Steam Users' Association, Sept., 1896. Our readers may remember that the last-named association was organized by Mr. Edward Atkinson, president of the Manufacturers' Mutual Fire Insurance Association, for the purpose of acquiring and distributing among its members information on subjects related to the economy of steam and of fuel. The association had a life of only one year, but its unfinished work has been taken up by the Mutual Boiler Insurance Co., of which Mr. Atkinson is also president and Mr. R. S. Hale, who was the expert of the Steam Users' Association, is Consulting Engineer.

---

*Condensed from a paper read at the Cincinnati meeting of the American Foundrymen's Association, June 7-10, 1898.

The circular on "Cost of Boiler Room Labor" is an interesting compilation from statistics furnished by over 100 factories in New England, New York, New Jersey and Pennsylvania, giving particulars of their boiler plants, wages paid to firemen, kind and amount of coal used, etc. The statistics are studied and arranged so as to throw all the light possible on the subject, and some interesting conclusions are drawn from them by Mr. Hale. Some of these conclusions are as follows:

> It takes no more hours of labor to fire a ton of hard coal than of soft coal.
>
> Firemen in hard coal plants receive higher wages by 50 cts. to $1 a week.
>
> The men fire more coal (about 15%) and receive more pay (about 10%) in the plants that run 24 hours a day instead of 10 hours a day.
>
> The cost gradually decreases as the size of the plant increases, becoming, however, nearly stationary at 200 tons per week.
>
> The labor per ton of coal is about 10% less for a steady load than for a variable load.
>
> Handling coal should cost about 1.6 cts. per ton up to five yards, and then about 0.1-ct. per ton per yard for each additional yard.
>
> Wages of firemen and work done per man are about the same in all the states named.
>
> One man (besides night man) can run engine and fire up to about 10 tons per week. One man (besides engineer and night man) can fire up to about 35 tons per week; two men to about 55 tons, and three men to about 80 tons. These figures assume that the night man does all he can of the banking, cleaning and starting. These figures are for average conditions.
>
> Mechanical stokers save 30 to 40% labor in very large plants, 20 to 30% in medium sized plants, and no labor in small plants.

The average figures obtained from 21 Eastern plants, using soft coal and running 10 hours a day are given below:

Plants using tons per week..	100 or over.	200 or over.	500 or over.	All plan's.
Number of plants averaged..	8	2	1	21
Tons coal per man per week.	26	28	33	21.3
Wages of firemen per week..	$10.99	$11.62	$13.25	$10.92
Cts. pr ton, all labor boilr-rm	.42	.42	.40	.52

Effect of Variable Load.

Plants with load..........	Steady.	Varying w'kly or monthly	Varying hourly.
Tons per man per week...	23.6	20.3	23.6
Cts. per ton.............	50	46	61

The lower cost in the plant where the load varies weekly or monthly (such as cotton mills with water power) is explained by the fact that these plants pay the lowest wages.

Effect of Forcing Boilers.

Rate of burning	Quick.	Medium.	Slow.
Sq.ft. grate for 1 ton per wk.	Undr 1.51	1.51 to 3	Over 3
Tons per man per week....	33.8	22.8	20.1
Wages of firemen per week..	$13.25	$11.47	$10.52
Cts. per ton	.40	.50	.54

The decrease in cost per ton as the rate of burning increases is said to be probably because the number of men allowed to a plant is based on the work the boilers might be called on to do, and not on the work they actually do.

Effect of Rate of Wages on Work Done.

Wages, firemen pr w'k.	$10 and under.	$10-$11	$11-$12	$12-$13	Over $13
Tons per man per w'k	22.2	20.3	21.2	20.5	25.3
Cts. per ton.	45	48	55	61	57

These figures do not seem to sustain the oft-repeated paradox that the "highest priced labor is the cheapest labor."

In Mr. Atkinson's introduction to this circular he calls attention to the fact that the average cost of shoveling coal in all the establishments reporting is 48 cts. per ton, while in one establishment the cost is only 26 cts. per ton. He then shows what a fine large sum would be saved to the mill owners if the average of 48 cts. was reduced to 26 cts. in all establishments, and says: "Why should not 26 cts. be the standard or objective point in nine-tenths of the boiler rooms of the factories and workshops where suitable space can be provided?"

We can tell Mr. Atkinson several reasons why. The establishment which averages only 26 cts. per ton as the cost of shoveling coal, burns 1,000 tons a week, runs 24 hours a day, employs 32 men, and pays them only $9.50 per week. It is quixotic for Mr. Atkinson to urge that small concerns employing only one to three firemen can reach any such figure for the cost of boiler-room labor, unless this establishment which shows the lowest cost is being run on an extravagant basis. Furthermore, we may remind Mr. Atkinson that with coal at the price which it is at most New England mills, it doesn't take long for a fireman to throw his wages into the furnace door. If it is attempted to economize by employing cheaper men as firemen or forcing them to shovel more coal than they can handle and fire carefully and economically, the mill treasurer will be apt to find that he has been saving at the spigot. There is plenty of waste going on in many boiler-rooms, but it is not usually in the direction of either too high wages or too little work for the men who attend the furnaces.

A NEW CONTINUOUS RECORDING OR INTEGRATING ENGINE INDICATOR.

The ordinary method of determining the power developed by a steam engine, by means of an indicator, is far from being satisfactory. Indicator cards can be taken only at intervals, and it frequently happens that just before or after the card is taken a change in load occurs, thus making it imperative that a considerable number of cards be taken to secure anything like accurate results. The diagrams thus obtained must be integrated, necessitating a laborious operation with the planimeter. The need, therefore, for some form of instrument which can be readily attached to any steam engine, and which will as readily give accurate measurement of the power developed by that engine, is too well known to be dwelt upon.

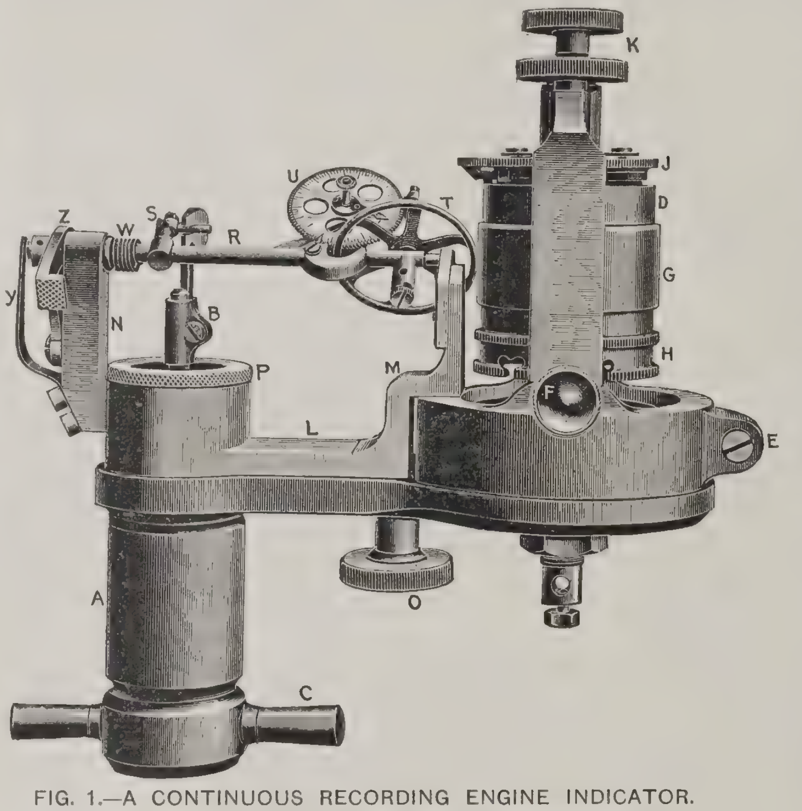

FIG. 1.—A CONTINUOUS RECORDING ENGINE INDICATOR.
W. G. Little, Bexley, Kent, Eng., Maker.

Many efforts have in the past been made to develop such an instrument, usually with small success, owing to the intricacy of the device or the delicacy of its parts. The instrument illustrated herewith is the latest and most successful of such attempts. It is the invention of Messrs. W. G. and C. W. G. Little, of Bexley, Kent, England, the former being at present the manufacturer of the indicator. Fig. 1 gives a fair general idea of its construction, showing also its simplicity. Briefly, the device can be best described by saying that the pencil movement of the ordinary indicator has been replaced by a planimeter wheel, rolling upon the drum as it is moved back and forth by the string attached to the crosshead in the usual way. This wheel is so connected to the indicator piston that as the pressure varies, the plane of the wheel is shifted relative to the axis of the drum.

Considering the parts separately, A is a steam cylinder containing the piston and spring, with the usual attachment screw coupling C and arm B. D is a drum provided with a coil drum, return spring, enclosed in the split case, E; F is a removable stop for the drum, D; G is a metal sleeve slipped on D and capable of being slid up or down, should its surface become worn by the indicator wheel; H is the groove in which the operating string is wound; J K is an ingenious device for measuring the length of the drum movement, and is supported just above the drum. It consists of a central piece upon which are two flat rings, one provided with a graduated scale, and the other with a vernier. By turning the knurled head, K, the inner ring is turned around until the projection on the swinging drum strikes a projection on the lower side of the ring. The other knurled screw is then turned until the drum projection strikes a lug on the vernier at the other end of its travel, when the exact stroke can be read directly on the scale and vernier at J to 0.005-in.

The integrating mechanism is mounted upon a separate frame, L M N, which can be removed from the cylinder by unscrewing the cap P. It consists essentially of a main axle, R, intersecting the axis of the drum, with an offset lever, S, and a planimeter wheel, T, with its axis at right angles to R, and two counting disks, U. The wheel, T, is dished so that the point of contact between it and the drum is always in the center line of R.

The recording device, U, consists of two toothed wheels engaging in a worm on the shaft of the wheel, T. The upper disk has 100 and the lower 99 teeth; the upper counter thus gains one division for each complete revolution of the lower. In this way considerable time may elapse between readings, as the counter can record 10,000 revolutions of the planimeter wheel. Two pointers are used, one on the frame, indicating units and tens of revolutions of the planimeter wheel, and the other on the counter indicating hundreds of revolutions of the counter.

Two styles of instrument are made, one for high speed engines, that is, above 200 revolutions per minute, for which a 1-in. travel is provided; the other for low speeds, with a large drum intended for a 2-in. travel. The drum speed in either case is not supposed to exceed 50 ft. per minute, and may be easily calculated by using the formula, Drum stroke × 2 × revolutions of engine per minute = speed in ft. per minute.

At the end of the shaft, R, is a coilspring, W, which holds the pin of the lever, S, against the bottom face of the crosshead, X, which is attached to the end of the piston rod. Y is a spring bearing on the cone end of R, its duty being to press the planimeter wheel, T, against the drum. Z is a device for applying or withdrawing T to start or stop registering.

To operate the instrument it is screwed onto the indicator stop cock, such as is usually found at the end of the engine cylinder. Some form of reducing motion is attached to the crosshead and the cord is adjusted to obtain the proper swing of the drum. The indicator spring should never be less than 20% above the maximum pressure obtainable at the engine. In starting, both pointers must rest on zero to avoid mistakes in reading. After turning on steam and allowing the instrument to warm up, indications can be taken by throwing the release Z, and noting the time. To stop registering Z is raised and the steam valve closed, the time being again noted. The following formula is then used for calculating the horse-power developed:

$(D^2 \times L \times K \times S) \times B =$ horse-power, in which

$D^2 =$ diameter of cylinder squared.

L = length of stroke of engine piston in ft.

K = constant of instrument =

$$0.000238 = \left(\frac{.7854}{33{,}000} \times 10\right).$$

S = scale of indicator spring.

s = stroke of drum in ins.

B = record on dial of instrument divided by the number of minutes run.

To obtain the mean effective pressure the formula

$$\frac{B}{\text{r. p. m.}} \times \frac{S \times 10}{s} = \text{M. E. P.}$$

is used.

This is based upon the fact that the dial record is always equal to one-tenth the area of a diagram which an ordinary indicator, with the same piston area, spring and a ratio of pencil to piston movement of 6 to 1, would give. To illustrate these formulae, assume an engine in which:

Diameter of piston = 6.5 ins. = D.
Length of stroke in ft. = .833 = L.
Scale of spring = 100 lbs. = S.
Instrument constant = 0.000238 = K.
Stroke of drum in ins. = 1.98 = s.
Record after 10 minutes = 90.

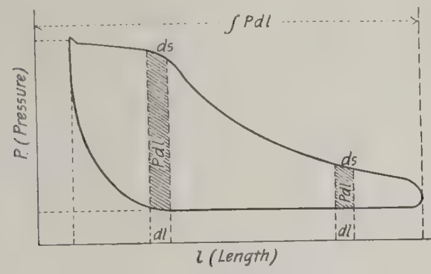

Fig. 2.—Indicator Diagram as a Measure of the Power Developed.

$$B = \frac{90}{10} = 9. \text{ for one minute, and}$$

$$6.5^2 \times .833 \times 0.000238 \times 100 = 0.837.$$

The record upon the dial is $\frac{1}{10}$ of an indicator diagram, $\frac{9}{1.98 \times 10} = 4.54,$ and .837 × 4.54 = 3.799 HP., or the power developed by the end of the engine cylinder to which the indicator was attached.

To determine the M. E. P. the dial is read for one minute, and the speed is taken for a like period. Assuming a speed of 212 revolutions per minute, and a reading of 9 on the dial for the same minute, then

$$\frac{B}{\text{r. p. m.}} = \frac{9}{212} = .0424$$

will be the record per revolution of the engine. The drum stroke is 1.98 ins., therefore, $\frac{.0424}{1.98} = .0214$, gives a value which, if multiplied by 100 (the indicator scale), and 10 (since the record is $\frac{1}{10}$ of the real), we have .0214 × 100 × 10 = 21.4 lbs. as the equivalent pressure which, if allowed to act on each square inch of the piston for the full stroke, would produce the same total effect, hence the M. E. P.

The theory upon which the instrument is based, and a proof of its correctness, may be illustrated by first considering the familiar indicator card such as that shown in Fig. 2. This curve shows the pressure at any instant, and the time through which that pressure is acting. If, instead of the pencil which traced this curve, we should use a roller or wheel, and desire to read directly from the wheel the power developed, it is essential that the circumferential movement produced must represent, either direct or proportionally, the product of the pressure and the distance through which that pressure acts, or again referring to Fig. 2, for the instant (d s), s representing time, the pressure acting is P, and the distance (d l). The power expended during the instant (d s) then will be P d l, and during the full stroke it will be the summation of all these efforts between the limits of the stroke, or

$$\int P\, d\, l.$$

If this movement is direct the dial could read direct; if proportional, a proportional factor must be used to determine the real power. As this instrument is constructed the proportional factor is 0.1.

To show that the circumferential movement obtained is proportional to the actual power, it is convenient to imagine the drum surface developed into a plane, as in Fig. 3. A B represents the direction of the motion of the drum, C D its axis of rotation, E F the plane of the planimeter wheel, G H the axis of the wheel, and O its point of contact with the drum. Suppose O K equal to the small length (d l) of Fig. 2, and O I equal to (d s). If we now move the wheel from O to K in the time (d t) there will be certain amount of slip and a certain amount of true rolling. The sum will be equivalent to sliding the wheel from O to I, and rolling from I to K, during which movement I K would correspond to the circumferential movement. Referring to Fig. 3, I K = O K sin φ, or since $\varphi = \beta$, I K = O K sin β, or d l sin β = distance moved by a point on the rolling surface of the wheel in the time (d t). Sin β or sin $\varphi = \frac{P}{L}$ (see Fig. 4), that is, sin β is proportional to P, or the pressure, and as has been already shown, the wheel movement is directly proportional to d l sin β. Hence, it is proportional to P d l, and also $\int$ P d l.

At first thought it would seem necessary to place the wheel, T (Fig. 1), perpendicular to the lever, S, but experience has shown that this is not the case, and as now constructed this angle is made about 35°, the object being to insure the necessary turning moment of the wheel at all angles apt to be encountered in working the instrument. In a series of careful experiments this angle of lead was also found to act as a compensating device balancing the small slip of the backward and forward motion in a most satisfactory manner.

Some experiments made by Prof. W. C. Unwin in 1895 gave excellent results, which compared very favorably with those obtained at the same time with a standard Crosby indicator. The early form has been improved until the instrument has now reached its present form, as shown in Fig. 1. Its accuracy is well shown in the following data, which represent comparative tests:

The first is a high speed test made at the works of Messrs. Willans & Robinson, Ltd., Rugby, Eng., on Dec. 22, 1897, using a standard Crosby indicator and a Little integrating indicator. Both were attached at the same time to the low pressure cylinder of a large engine running at 350 revolutions per minute on a steady electric load kept constant by adjusting resistance in the circuit:

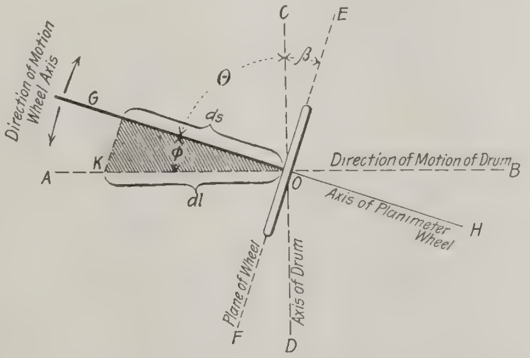

Fig. 3.—Drum Surface Developed into a Plane.

Crosby Indicator.

THE ENGINEER AS A USEFUL MEMBER OF SOCIETY.*

It is an all too common characteristic that the engineer is an engineer and nothing more. But this is not the stamp of engineer most needed, and therefore he is not fulfilling his greatest possible usefulness. The type of engineer I am advocating should be as follows: First, successful professionally; second, strong in business; third, influential socially.

Let us consider him along each of these lines. As a professional man he must necessarily be a well-trained man. This training may be the result of education or experience, or both. If he is consistent in his pursuit for it and is mentally endowed for it, he cannot but be strongminded. He must necessarily be a man of great application and concentration in whatever he undertakes. He is and must be honest. He does not hesitate to undertake the most unpromising tasks. He is, in brief, so constituted as to approach engineering tasks with indomitable courage and unfaltering assurance of success. He is cool-headed, slow to express a professional opinion, and, above all, a man who rarely asserts himself on subjects he knows little about. His course of study has been such as to make him essentially a man of clearly defined purpose. He counts not so much the financial as the mental profit in any undertaking. Thus far he is the engineer as he is publicly reputed to be, whether building vast edifices in our cities or opening up to civilization dense wildernesses.

Considering this ideal further, he should, as a business man, thoroughly understand the methods of the business world. He should know how commerce is conducted, the principles of banking, and how enterprises are organized and carried through. If there is any direction in which the average graduate from an engineering school is helpless, it is in that of understanding and being able to apply business principles. He is poorly qualified as a rule, even to the point of being able to protect himself. This partly arises from his concentration upon his preparatory engineering studies, and partly from his belief that engineering and commercial affairs are not in any sense kindred. He therefore enters upon his professional career pursuing purely engineering work. Subsequent opportunity rarely presents itself for him to acquire business experience, for the double reason that business men cannot entrust business affairs to inexperienced hands, and engineers who have attained some degree of professional reputation cannot afford to begin at the bottom of the commercial ladder. Quite too late for him to qualify himself, the average engineer begins to earnestly wish for a wider knowledge of business methods.

---

*From an address by W. A. Layman, delivered at the commencement exercises at Rose Polytechnic Institute, June 16, 1898.

The ideal engineer will also play an influential part in social life. By social life I do not mean that existence eked out in so-called society circles. On the contrary, I mean social life in the broadest sense of fellowship with one's fellow men. The engineer so qualified will be interested in the political life of his immediate community, as well as that of the nation. He will study civil and criminal law to that extent which every good citizen is called upon to study it. He will contribute his share to the alleviation of distress, physical and political. He will mingle with his neighbors, studying to add to their comfort in and enjoyment of life. He will be a student of current affairs. He will make some study of literature. He will know what to read, and how to read and how to write. He will not necessarily be pre-eminent in social fields, but will be what is generally termed a well-informed and cultured man.

* * *

EXPERIMENTS UPON THE DURABILITY OF DIFFERENT METAL COATINGS IMMERSED IN SEA WATER.

In 1896 an interesting test was made at the Brooklyn Navy Yard to determine the relative durability of different protective coatings for metal when immersed in sea water. This test was conducted by Edward Smith & Co., of New York, under the personal direction of Prof. A. H. Sabin, Assoc. M. Am. Soc. C. E., of that firm, and with the permission and aid of the Navy Department. Briefly described the test consisted in covering thin plates of steel and aluminum with different protective coatings, placing these plates in cages and sinking the cages in about 6 ft. of water at the Navy Yard. The plates had an area of about 2 sq. ft. on each side and were so placed in the cages that both sides were fully exposed to the action of the water, which at this point is very foul with sewage and the collections of the harbor.

The cages were allowed to remain under water for six months and then were hauled out and an examination made of each. Altogether there were 84 plates. The results of this examination, the nature of the different coatings and other details of the test were published in a paper read before the American Society of Civil Engineers on Nov. 4, 1896, by Prof. Sabin. While this test led to a number of interesting conclusions, it showed the need also of further tests; and accordingly in the summer of 1897 another set of plates were immersed. This second set of plates was removed from the water on July 21, 1898, after an immersion of 13 months, in the presence of a number of engineers and visitors. The accompanying notes of the condition of these plates were taken by one of the editors of this journal, who was present, and examined them upon their removal from the water.

Altogether 133 plates were immersed in this second test. They were placed in six cages. Only two cages and half of a third could be recovered, however, and the accompanying table contains the result of the test of the 72 plates only, which these contained. An attempt will be made to dredge up the remaining plates for examination at some future date. Of the 72 plates recovered, twelve were plates which had undergone the 1896 tests and which were immersed a second time. These twelve plates were, therefore, immersed for 19 months altogether. The remaining 60 plates were new when immersed, and, as already stated, were under water for 13 months.

The different coatings with which the plates were covered are described in the table, and with a brief explanation these descriptions will be clear to nearly everyone. The ordinary oil and resin varnishes are made by compounding certain fossil resins with various proportions of refined linseed oil, and the essential differences in varnishes are due chiefly to the kinds of resin used and the proportion of oil. For convenience it is customary to assume 100 lbs. of resin as a unit. A 20-Kauri varnish, therefore, means a varnish resulting from compounding 20 gallons of oil with 100 lbs. of Kauri resin. A similar terminology is adopted for varnishes made of Zanzibar or Manila resin. Where the coating is described as "air dried" it is meant that is was allowed to dry onto the plate at ordinary temperature, and where it is described as "baked" it is meant that a heat of 215° to 240° F. was employed to bake the coating onto the plate.

In examining the plates they were simply removed from the cages, washed to remove the slime and loose marine growths, and inspected while wet. Only a few moments were given to the examination of each plate as it is intended to examine them more carefully when they have thoroughly dried. Until the results of this final study are collated it is, perhaps, best not to pass opinion upon the comparative behavior of the different coatings in detail. One or two broad conclusions, however, seem to follow from the facts given. It is pretty plain; (1) that whatever pigment is used, a more durable coating for marine work results if varnish is used as the vehicle than if oil is used; (2) that a varnish coating or a pigment and varnish coating seems to endure sea water better when baked on than when merely air dried on; (3) that white zinc is probably acted upon as little as any pigment which was used in the test, and (4) that enamel coatings baked on at high temperatures are apparently the most durable of any.

TABLE SHOWING RESULTS OF TESTS OF PROTECTIVE COATINGS APPLIED TO STEEL AND ALUMINUM PLATES IMMERSED FOR 13 MONTHS* IN SEA WATER AT BROOKLYN NAVY YARD.

No. of plate.	Character of vehicle.	Character of pigment.	Preparation.	Condition of plate and coating.
			Aluminum	Plates.
151	20 Kauri varnish	None.	Air dried.	Edges blistered; no considerable corrosion.

272	Bowles' paint.	....	"	Good condition; few blisters.
273	Rahtjens paint	....	"	Coating badly gone; considerable corrosion; few barnacles.
274	McInnis paint	....	"	Very good condition; no barnacles.
275	International Holtzapfel..	....	"	Coat'g badly gone; considerably corroded; sm'l barnacles.
277	Red lead and white zinc ..	....	"	Soft, gone in spots; corroded on edges.
278	Red lead and white zinc ..	....	"	Soft, gone in spots; corroded on edges.
281	20 Kauri varnish	None.	"	Discolored on edges by rust; not deeply rusted.
282	30 " "	"	"	Small blisters; not deeply corroded.
283	40 " "	"	"	Pin-head blisters; not deeply corroded.
284	30 manila varnish	"	"	Numerous small blisters; not deeply corroded.
285	30 Zanzibar varnish	"	"	Many pin-head blisters; little corrosion.
286	Spar varnish	"	"	Badly destroyed; considerable corrosion.
287	I X L No. 2 varnish	"	"	Many pin-head blisters; not much corrosion.
288	Raw oil	"	"	Coating destroyed; badly corroded.
289	Durable metal coating ...	....	"	Many small blisters; little corrosion.
			Steel Plates Reimmersed after 1896 Test.	
1	20 Kauri varnish	Flake white.	Air dried.	Rusted on edges; discolored; good condition otherwise.
2	20 " "	"	Baked.	Rusted on edges; discolored; good condition otherwise.
16	20 manila varnish	White zinc.	"	Some blisters; one side considerably corroded.
18	8 " "	Flake white.	"	Hard; pretty good condition.
20	30 Zanzibar varnish	White zinc.	"	No blisters; no corrosion.
22	20 Zanzibar varnish	"	"	Few blisters; some corrosion; hard.
35	Sabin Process pipe coating enamel........		....	Some corrosion on one edge; otherwise good condition.
			Aluminum Plates Reimmersed after 1896 Test.	
113	Sabin Process pipe coating enamel........		....	Two small blisters; otherwise good condition.
104	White zinc ground in varnish, one side baked.........			Three or four small blisters; otherwise good condition.
122	White zinc ground in varnish, one side baked.........			Three or four small blisters; otherwise good condition.
105	Chromium oxide ground in varnish, one side baked....			Few small blisters; generally excellent condition.
124	Spar varnish, one side baked			Two or three small blisters; no considerable corrosion.

*The twelve plates from the 1896 test were immersed six months longer than the others, or nineteen months altogether.

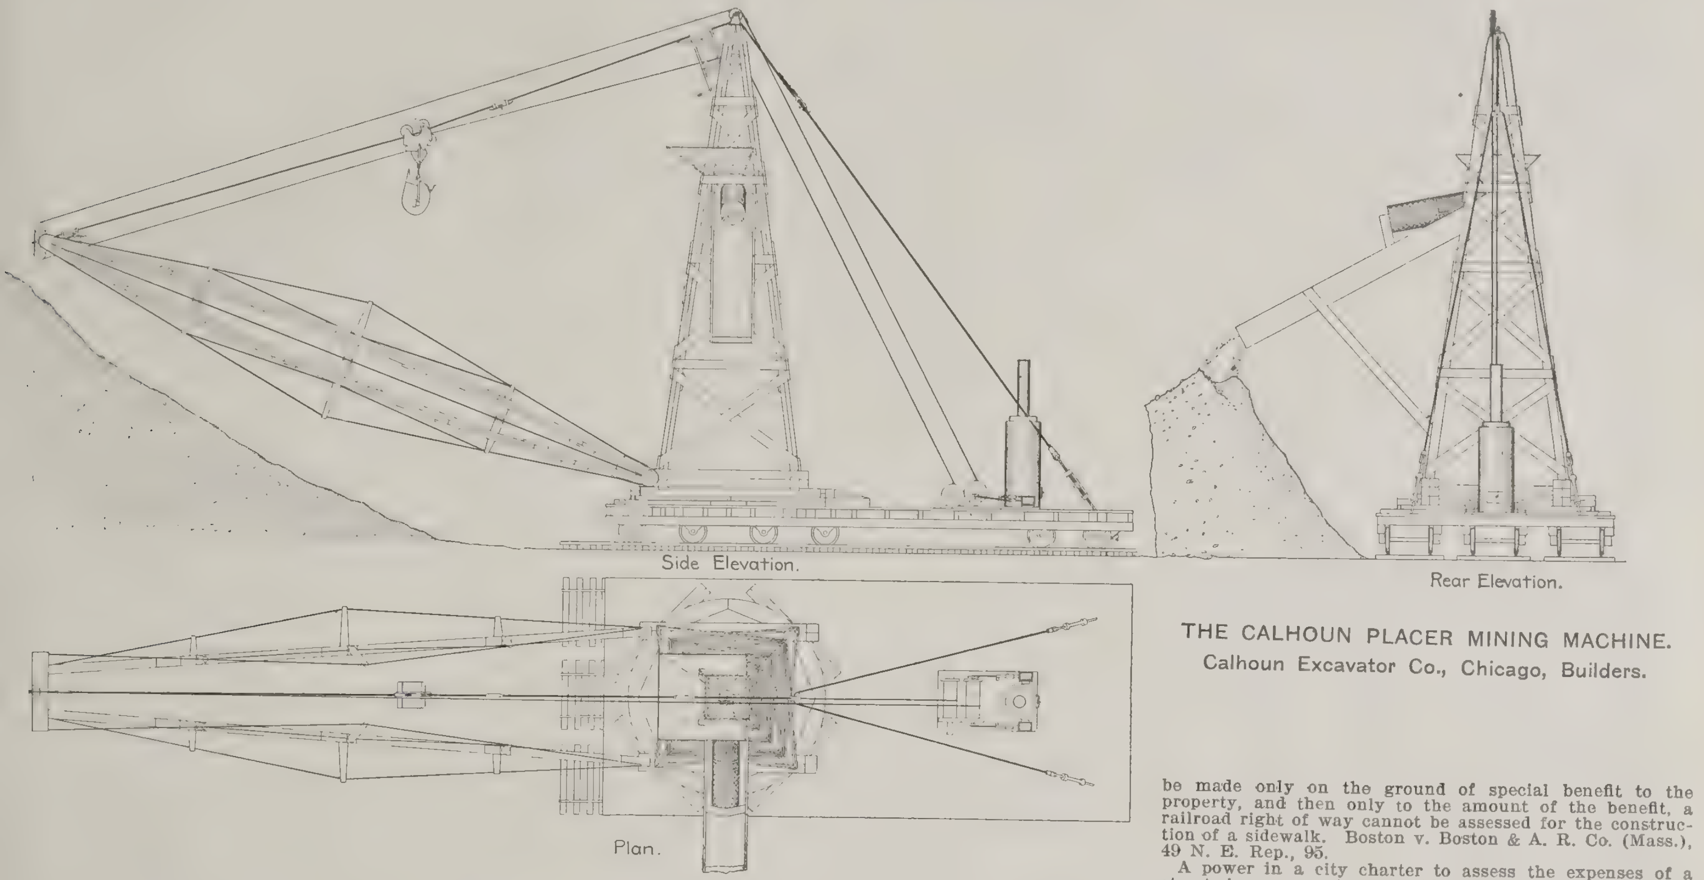
THE CALHOUN PLACER MINING MACHINE.

The cheap and simple apparatus for placer mining and gravel washing, which is shown in the accompanying cut, is an adaptation to this particular work of the Calhoun excavating machine, which was illustrated and described in detail in our issue of April 15, 1897.

The machine is entirely self-contained, and consists of a tower, boom, hoisting plant and washing plant, all mounted on a large platform car running on three sets of tracks. The tower rests on a pivoted turntable, so that the boom can be swung to either side and make a cut sufficiently wide for the progress of the machine. At the rear of the car are placed the hoisting engine, pumps, etc. Near the front end of the car is the frame tower, about 50 ft. high, over the top of which pass the running, hauling and tail ropes. In this tower is a hopper, discharging into a revolving screen placed over an inclined chute. This chute has two floors, the upper one carrying the coarser material, which passes through the end of the screen, while the lower one forms the riffle box for retaining the gold carried down with the finer gravel, which passes through the meshes of the screen. The lower floor can be made of sufficient width to admit of several partitions, thus giving a greater surface of riffles. A pump supplies a continuous stream of water to the hopper and the riffle box, and the debris is delivered clear of the cut and out of the way of the machine.



THE CALHOUN PLACER MINING MACHINE.

Calhoun Excavator Co., Chicago, Builders.

From the front side of the bottom of the tower extends a double boom about 70 ft. long, composed of two trussed members connected at their outer ends by a transverse timber, to which is attached the running rope, and on which are the sheaves for the tail rope. The running rope passes over the tower and has at its rear end a sheave, through which passes the back-stay cable, whose ends are attached by turnbuckles to anchors at the rear corners of the car. This arrangement permits of adjusting the slope or angle of the boom. The tail rope passes from the rear drum of the hoisting engine over the top of the tower, down to the end of the boom and back to the carriage, to which its end is attached. The hauling rope is also attached to the carriage, and passes under a sheave in the bail of the bucket, over a guide sheave in the carriage and back through the top of the tower to the front drum of the engine.

In the illustration the carriage is shown on its trip up with a loaded bucket. On reaching the tower the bucket is reversed and emptied by the tripping device, and is then started downward by the tail rope. When it reaches the detaching device on the hauling rope (which is placed just over the toe of the slope), the bucket is released from the carriage and drops vertically to the ground, where it automatically takes position for loading as it is pulled up the slope. Meanwhile, the carriage is pulled on down the running rope and is automatically locked by a latch at the end of the boom until the loaded bucket is again in place and locked to the carriage, when the catch is released. With proper handling, the bucket can make one trip per minute.

The machine may be built of wood, and has been designed for strength and durability under hard work and rough usage. Buckets of ½, 1 or 1½ cu. yds. capacity may be used. It is manufactured by the Calhoun Excavator Co., 628 Unity Building, Chicago, Ill., and further information will be furnished by the manufacturers on application. The California Wire Works, of San Francisco, Cal., have the agency of the Calhoun excavator for the Pacific Coast states, and will furnish information to interested parties in that territory.

LEGAL DECISIONS OF INTEREST TO ENGINEERS.

Damage for Trolley Poles.

The poles and wires of an electric railway are an additional burden upon the street, not contemplated in the original dedication, made by a plat filed in accordance with law, and the abutting lot owners are entitled to whatever damages their property has sustained by reason of such location, especially where they interfere with his ingress and egress from his lots. Jayne v. Omaha St. Ry. Co. (Neb.), 74 N. W. Rep., 67.

Liability on Acceptance of Defective Work.

A contractor is entitled to recover from the other party who accepts the work and receives the benefit from it, although there was not a strict compliance with the special contract under which it was done, the contract price less such sum as will fully compensate the other party for the imperfections of the work or insufficiency of the materials. Smith v. Packard, 27 Southeastern Rep. 586.

Liability to Repair Pavement.

A contractor cannot avoid effect of provisions of his contract that he shall keep the pavements in good repair for a certain number of years, without cost or expense to the city, and that he shall assume the risk of damage to the work which may be occasioned by the caving in of the street, or from any other cause whatever, upon the ground that the caving rendering the repairs necessary was the result of the negligence of the city in filling such excavations before he did his work, and of which he had no notice. Warren-Scharf Pav. Co. v. St. Paul, 72 N. W. Rep. 711.

Railroads and Street Assessments.

Since assessments, under the laws of Massachusetts, can be made only on the ground of special benefit to the property, and then only to the amount of the benefit, a railroad right of way cannot be assessed for the construction of a sidewalk. Boston v. Boston & A. R. Co. (Mass.), 49 N. E. Rep., 95.

A power in a city charter to assess the expenses of a street improvement upon "lots and parcels of land" deemed benefited by the improvement confers no authority to assess on the tracks, ties, or franchises of a street railroad company. Conway v. Rochester, 49 N. Y. Supp. Rep., 489.

Liability for Flow from City Drains.

A municipal corporation which has increased the flow of water in a certain direction is only bound to exercise reasonable care in providing means for carrying off the surplus; it is not an insurer against unprecedented floods or cloud bursts. Keithsburg v. Simpson (Ill.), 70 Ill. App. Ct. Rep., 467.

A village by connecting its sewers, etc., with private drains, and draining the surface water of streets and sewers into same, becomes responsible for damage done by polluted water passing through them, to the same extent as it had originally connected such private drains, and is liable for the whole of the damage. Kewaunee v. Ladd, 68 Ill. App. Ct. Rep., 154.

The number on the address label of each paper indicates when subscription expires, the last figure indicating the year and the one or two preceding figures the week of that year; for instance, the number 328 *means that subscription is paid to the* 32*d week (that is the issue of Aug.* 11) *of the year* 1898; *the change of these figures is the only receipt sent, unless by special request.*

ADVERTISING RATES: 20 *cents per line. Want notices, special rates, see page* 18. *Rates for standing advertisements sent on request. Changes in standing advertisements must be received by Monday afternoon; new advertisements, Tuesday afternoon; transient advertisements by Wednesday noon.*

Our readers who may be searching for amusement in these midsummer days, cannot do better than turn back to our issue of May 12, in which we reprinted the comments of "The Engineer," of London, on "Spain's Armored Cruisers." With the results of the Santiago engagement fresh in mind, it is highly entertaining to read the following:

> We find, therefore, that to all intents and purposes the Spanish "Vizcaya" class are battleships of the second class. * * * * The "Cristobal Colon" could and no doubt will "lie in the line" if there is a naval action; she is proof against every sort of shell. Except her and the "Pedro d'Aragon," now building, which carry 10-in. guns, all the Spanish armored cruisers carry a couple of 11-in. guns; very good pieces, able to penetrate all the armor on the American battleship's guns.
>
> The American armored cruisers are quite different; they are really armored cruisers. Their belts, instead of being 12-in. steel, as in the "Vizcaya's," are of 3-in. steel only; their big guns are only of 8-in. caliber. Now, an 8-in. projectile is quite useless against the belts of the "Vizcaya's," or against their barbettes, and in engaging such ships shell fire alone could be depended on to do anything. Of course, shell fire is the staple attack, but the "Brooklyn" and "New York" can do nothing against the Spaniards, with their comparatively feeble 8-in. shell, that the Spaniards cannot do against them with a far more powerful gun. It is rank heresy, maybe, but we cannot but hold that there is a tendency to unduly glorify the small quick-fire gun or the medium-sized 8-in. The chances of hitting are, of course, greater with the smaller weapon, both from its extra rapidity and its extra numerical quantity; but when the big shot does hit its effect will be, of course, far greater.

The latest news from Santiago is that the wrecks of the Spanish cruisers show eight 4-in., twenty 5-in., ten 8-in. and only two 12 or 13-in. shot holes above their present water lines. In view of this record "The Engineer" will probably modify its opinion as to the effectiveness of the 5-in. and 8-in. guns on the American vessels. The fitness of the "Colon" to "lie in the line" seems to be proved, but it is in line with the other wrecks on the Cuban coast and not in the line of battle.

◆

The issue of "The Engineer" of July 8, contains some very unique comments upon the Santiago battle; its information has evidently been gathered from highly inaccurate sources, and its criticism is correspondingly wide of the mark. It betrays the most astonishment that the American vessels were so promptly got under way, when the Spanish cruisers appeared. "It is difficult to believe," it says, "that the American ships could have remained under full steam habitually, yet it is clear that they were so when the Spanish fleet came out. * * * * We must conclude, that if, as they say, they were taken by surprise, they were fortunate enough to have steam up for some other purpose."

Our contemporary is evidently a long way from comprehending the way they do things in the American navy. Upon the fleet before Santiago was placed the responsibility of preventing the escape of Cervera's cruisers. These were assumed to be ships of speed enough to escape from any of our battleships and power enough to defeat any of our other vessels. The sequel showed, indeed, that neither of these assumptions were true; and there were, of course, many reports before the battle as to the defective condition of the machinery and hulls of the Spanish vessels. The American commanders, however, would have been derelict in their duty had they allowed such reports to influence their action. Their business was to keep at all times sufficient vessels at the harbor entrance and ready for instant action to fight and destroy Cervera's fleet should it issue forth. To lie with fires banked and steam down, as the Spanish fleet did at Manila, would have been crass stupidity. It is safe to say that in all the weeks our vessels mounted guard off Santiago, there was never a time when furnace fires were not kept bright enough to keep up steam in the boilers, so that the ships could get under way at a moment's notice.

◆

Other conjectures of "The Engineer" are hardly less amusing; but it caps the climax at the close with the following:

> The American fire was sufficiently well aimed to tell, while the whole of the Spanish fire seems to have been wasted. Even the Chinese at Yalu produced much greater effect with their unsuitable solid steel shot than the Spanish guns on this occasion. This suggests a ghastly possibility. Did the Spanish fire blank, owing to the absence of projectiles? Some shot they doubtless had; even the splashes prove this, but they may have been very few.

We have heard much from various sources as to the inefficiency of the Spanish navy; but "The Engineer's" conjecture that Cervera's fleet came across the Atlantic to take part in the war with its magazines chiefly supplied with blank cartridges is a little beyond belief. "The Engineer," we may remark, is in a chronic state of worry over shortness of ammunition. It is sure that Dewey's squadron has not enough left to bombard Manila with, and it has presented figures to prove that the American vessels at Santiago ought to have used up all their ammunition in fifteen minutes. But it apparently forgets that Cervera's vessels had never been in action at all until they came out of Santiago Bay to try and make their escape. If they ever had any ammunition, they had it then; and if they had nothing but blank cartridges they would have never taken the trouble to fire their guns.

◆

Since the above was in type, "The Engineer," of July 15 has come to hand, in which we find further comments on the Santiago battle and more preposterous delusions as to the facts. Our contemporary still cherishes the idea that the American fleet maintained its blockade of Santiago with banked fires, and says it has now heard that "it had been apparent to the American ships that the Spanish ships were getting up steam and, consequently, they did the same." It then proceeds to draw with great gravity, as one of the lessons taught by the war, the following:

> To make a dash through a superior fleet, it is desirable to secure the lead in getting up steam.

Our contemporary's misinformation is by no means confined to this point, however. It is in a state of profound astonishment as to the "total disproportion in the effect of the American guns to that of the Spanish." In attempting to explain this, it seizes on a rumor that some of the principal guns had been removed from the Spanish ships, and declares that "this is too awful to call for comment."

From the same trustworthy informant, we presume, it has heard that the torpedoes on the Spanish vessels "seems to have lain on deck and formed mines for the enemy's shells to explode." On the basis of such cock-and-bull stories as these our contemporary adds the following gems to its list of "lessons taught by the war":

> A ship loses in fighting power if she omits to take her principal guns on board.
>
> Shots that only strike the water and make splashes produce no real effect on an enemy unless he is strangely nervous, consequently even quick fire is no use unless well directed.
>
> Torpedoes should not be left about exposed under a hot fire.

These and other "lessons" of similar profundity our contemporary propounds with the gravity befitting an original discoverer of great truths. It is to be hoped that the folly of "only striking the water and making splashes in the hope of producing an effect upon the enemy" will be appreciated in future by all naval commanders. To quote again our highly entertaining contemporary:

> Nay, apparently, had they fired a quantity of blank cartridges which made a thick smoke they would have done the Americans nearly as much harm as they did and perhaps made it more difficult to deliver a well-aimed fire at them.

After this we can only congratulate ourselves that the author of these novel naval tactics was not in command of the Spanish fleet.

◆

The New York Canal traffic thus far this season has fallen far below even the low record of last year. The total to July 16 is but 5,453,000 bushels, against 7,238,000 bushels in the same time last year. The poor showing is ascribed to the numerous breaks in the canal, which have delayed the boats, and to the opening of the canals a week later than usual. On the other hand, the total grain receipts at New York since May 1 have been more than 7,000,000 bushels larger than last year; and the elevator pool at Buffalo, which has for so many years been denounced as the chief enemy of the canals, has been broken. Instead of the old standard rate of ⅞-ct. per bushel for elevating grain at Buffalo, the rate this year has dropped as low as ⅛-ct. The railways, however, also have the benefit of the lower elevator charge, and it is said that they are now transferring grain from Lake steamers to cars at Buffalo in some cases without charge. Another notable fact is that nearly all the canal grain traffic has been in corn and oats. Only 16,000 bushels of wheat have been shipped by canal up to date this season, while the railways have brought to New York nearly 17,000,000 bushels. Apparently, in the rapid fluctuations of the market the slightly cheaper rate on the canal has cut no figure in comparison with the greater dispatch of the railway. The grain shipper had rather pay two or three cents more a bushel than run the risk of a drop in price of three or four times that amount. In view of the fact that since the canals opened the railways have carried seven-eighths of the grain traffic, and that the total amount of grain coming to New York has increased at the same time that the canal traffic has fallen off, those who urge the maintenance of the canals as essential to New York's supremacy in the export trade may find it necessary to revise their opinions.

◆

A test of the Ellithorpe air cushion for elevators was made in the new Empire Building, Broadway and Rector St., New York city, on July 18. The building is 20 stories high. The air cushion is formed by making that portion of the elevator shaft from the basement to the level of the third floor an enclosed well, with sides of riveted steel plates and steel doors which are enclosed in strong frames in such a manner as to prevent their being blown out by the air pressure which would be developed by the sudden descent of a car. The test was made by suspending by a short rope from the bottom of the regular elevator car, another car, an old one, weighing about 2,000 lbs. This was raised to the top of the shaft, the rope was cut and it fell. On the floor of the old elevator were arranged a dozen eggs, four glasses of water, and the globe of an incandescent lamp, with the idea, says a press report of the test, that if they passed through the ordeal a man could safely do so. A preliminary test was made by dropping the car from the 10th story. The eggs and the lamp globe remained unbroken, and only a few drops of water were spilled. Then the test was made by dropping the car from the 20th story. The report states that its velocity when it passed the third

floor was 126 ft. per second, nearly 1½ miles a minute. This corresponds to a free fall of 250 ft. It also says that the second test was considered just as satisfactory as the first, "although the frail woodwork at the back of the car was wrenched out of place, the eggs remained unbroken." Nothing is said about the glasses of water and the incandescent lamp in this test.

The idea that if an egg could pass through this "ordeal" a man could, appears to us a little doubtful. Consider a man weighing 160 lbs. standing on the floor of an elevator car falling at the rate of 126 ft. per second, which would be its speed at the end of a free fall of 250 ft. The energy of the descending man would be 160 × 250 = 40,000 ft.-lbs., and this amount of energy would have to be absorbed before he could be brought to rest. Suppose his speed were checked at a perfectly uniform rate so that he would come to rest at the end of a further descent of 50 ft. If the man remained in an upright position the pressure he would bring on the floor of the car, and the reaction of the car on the soles of his feet would be 40,000 ÷ 50 = 800 lbs. That is, during the whole time during which the descent of 50 ft. lasted, the man would practically weigh 800 lbs. If during a portion of this time the rate of reduction of speed should be greater, the pressure of the man on the floor of the car would also be much greater. The chances are that the man would not remain in a vertical position. He would be likely to bend his knees with such suddenness as to fracture his knee-caps, and if his weight were then taken on his hands his arms would be broken, or if not he would experience a probably fatal concussion of the brain or of the spine. It may be said that all this is theory, however, and the practical test shows that the eggs were not crushed. But why should they be? We have made a little experiment with eggs, and here are the results: Three eggs weighed together 5½ oz. They were put on a small plate, and another plate was placed above them, making a platform on which was piled a weight of 13 lbs. before the eggs were crushed. That is, an egg subjected to a crushing force between two plates resists a pressure equal to about 38 times its own weight.

When a falling elevator car is gradually checked by an air cushion, the effect upon an egg in the car is to increase its pressure upon its support, just as in the case of the man. But the rough test which we have cited above seems to indicate that the egg could be subjected to a retarding force equal to 38 times its own weight before its shell would crush. A 150-lb. man under such a force would have a pressure of no less than 5,700 lbs. on the soles of his shoes, if he could continue to stand erect, which would be, of course, impossible.

Of course we are supposing in each case the retarding force to be applied without shock, for a very trifling shock would crush the egg, while the man has elasticity enough in his anatomy to absorb without injury the shock from a free fall of several feet. When it comes to a fall of ten or twenty stories the air cushion test simply proves that eggs are stronger than they are generally supposed to be, but it proves nothing, so far as we can see, as to what would happen to a man in an elevator car under the same conditions of fall.

* * *

THE VALUE OF HIGH SHORT-TIME TENSILE STRENGTH TESTS FOR HYDRAULIC CEMENTS.

Quite a large number of cement specifications published recently have challenged comment on account of the enormous tensile strengths which they require both natural and Portland cements to develop in one, seven and twenty-eight day tests. In certain instances which have come to our notice the tensile strength requirements of the specification ran as high as 175 lbs., 500 lbs. and 600 lbs. for Portland cement at these respective ages, or from 30 per cent. to 40 per cent. higher than engineers usually require for the same classes of work. Figures for natural cement when compared run much the same way.

It is a legitimate question, we think, whether such very high tensile strength requirements are desirable. Certainly the question may be raised whether in the ordinary run of engineering work there is any good reason for such differences in practice as the figures just quoted show. It must be either that too low requirements are being demanded by engineers generally, or else that in these exceptional cases a value is being set on very high short time tests which is largely fictitious, and it should be determined which case is really the true one. The necessity for making such an investigation is increased by the fact that these high-test specifications have been made the subject of such extended mention in engineering papers and elsewhere that they are being accepted without question by many persons as being a generally recognized improvement in engineering practice. Time may, indeed, show this to be the case, but at present their position in this respect is not unassailable, and it may be beneficial to some of our readers who have not studied the question to point out the possible objections to these very high short time cement tests.

The first thought that comes to one is that we have the irrefutable evidence of hundreds of structures built with mortars and concretes made from the low strength cements and hydraulic limes of a half century ago that such cements in most cases retain their durability and develop strengths which are adequate to all demands. The rock-like consistency and hardness of some of this early cement work has indeed often been the subject of special remark by engineers who have had occasion to examine it. Most of these cements probably would not have withstood the short time tensile test demanded of natural rock cements today, and they certainly would have failed to give even approximately the high strengths demanded of Portland cement at early ages by the figures just quoted. It may be argued, of course, that if these low strength cements have proved so efficient, the high strength cements of to-day will be proportionately better, but this is not necessarily a correct deduction, as will be shown a little further on.

Meanwhile it may be pointed out that apparently the opinion is exceptional, rather than general among engineers that such very high short time strengths are desirable. The current American and European specifications for Portland cement which are published elsewhere in this issue bring out this fact very clearly, as a brief glance at the accompanying summary of the more detailed figures will show:

	Tensile strength in lbs. per sq. in.				
	Neat cement.			3 sand 1 cement.	
Specifications.	1 day.	7 days.	28 days.	7 days.	28 days.
European governm't.	None.	347	528	119	204
U. S. government..	114	394	536	129	199
91 misc, American.	134	384	528	118	189
General average ...	124	375	531	122	197
Philadelphia, Pa. ...	175	500	600	170	240

To emphasize the difference between average practice, as shown by these figures, and the exceptionally high test requirements referred to, the figures of tensile strength required of Portland cement in public works in the city of Philadelphia, Pa., are appended to the table in shape for direct comparison. As we have previously stated, these requirements are the most severe of which we know. Even the specifications for the U. S. Government lighthouse work are not higher, and there, if in any class of engineering work, it would seem that great strengths at early ages might reasonably be demanded of the cements which are used.

The figures in the table can be compared by each person for himself. All that it is necessary to remark here is that the superior advantages of the highest at least of these short time tensile strength requirements for cements are not recognized by the actual practice of engineers who have in charge the most important works in which cements are employed. The inference is at least fair, then, that such high strengths at early ages are of doubtful value in practical construction. Leaving the question of prevailing practice out of the argument, however, let us inquire what the advantages of unusual strengths at early ages are likely to be in the light of the duties which cement is ordinarily called upon to perform.

It is fair to say, we think, that nothing like the full ultimate strength of a cement is required at such early ages as one week or even four weeks in by far the greater number of places where this material is used. In lighthouse work, or in breakwaters, jetties and similar marine constructions exposed to the fury of the waves, it may be desirable for the masonry to develop its full strength at a very early age, but in the majority of engineering works this is not true. The quality which the engineer really wants most is that the cement shall develop a fair strength in one week or in four weeks and shall gradually increase this strength and maintain it as long as the structure may be called upon to endure. In other words, the whole matter simmers down to the question of durability.

The inquiry then comes up whether cements which show unusual strengths at early ages are any more durable than others. Cement literature, so far as we know, contains nothing to show that they are. There are several things, however, which tend to show the contrary. It is very commonly remarked by those who have made long tests of Portland cements that those cements which showed exceptionably great strengths at early ages were far more likely to become brittle with age than those which tested lower at first. This is exactly what we should expect from our knowledge of rock crystalization. In rocks it is well known that the more rapid the hardening the more imperfect and uneven in shape, size and texture are the crystals until they finally disappear altogether and the material comes out glass instead of stone.

Unfortunately, exact figures are largely lacking upon this feature of the hardening of cements, but some suggestive tests which bear indirectly upon it were published by Mr. R. E. Middleton, M. Inst. C. E., in London "Engineering," of April 6, 1888, which are worth quoting in lack of more comprehensive proof. Mr. Middleton's figures are as follows:

No. of test.	Age, days.	Strength, lbs.	Age, days.	Strength, lbs.	Age, days.	Strength, lbs.	P. c. gain or loss.
1.	7	258	942	440	1,325	550	+ 113
2.	7	320	900	635	1,283	577	+ 75
3.	7	371	982	560	1,365	599	+ 61
4.	7	419	1,040	435	1,423	492	+ 18
5.	7	479	1,088	542	1,471	551	+ 15
6.	7	534	858	545	1,241	526	— 1.5

These figures apparently show that cements which test from 250 lbs. to 350 lbs. in seven days increase in strength more and retain their strength better than do cements which test from 400 lbs. to 600 lbs. at the same age. It would be manifestly improper to conclude from these figures alone that the same result would always follow, but they are rather significant when taken in connection with other evidence.

But even supposing that cements which show a strength of from 500 lbs. to 600 lbs. in seven-day tests do not deteriorate in any way, what particular advantage follows their employment? The case is evidently not like the case where structural steel, for example, is the material employed. If by some new metallurgical process we increase the efficiency of a steel bar to do work we at once reap a direct gain in the reduction in size and weight of the members which we must put into our structures. It is not so in using a cement which tests 50 lbs. or 100 lbs. more than others. The conditions of its employment in the great majority of engineering works are such that very little if any reduction is possible in the amount of material which must be used whatever its strength may be.

There is another phase of the matter also which may be enlarged upon in this connection. It costs more for the manufacturers to produce a cement which will test 500 lbs. in seven days than it does to produce one which will test 300 lbs. at that age. Unless a proportionate advantage is gained by reducing the quantity and weight of the cement employed or by an increase in its durability, in using the high-testing material, therefore, this extra cost is a waste of money. Furthermore, as many cements cannot be made to develop such great strength by normal means, manufacturers, in order to meet the high test requirements demanded, use adulterants, which are always useless and may be exceedingly detrimental to the final strength and durability of the cement. So common had this practice of adulteration become in Germany a few years ago that both the manufacturers and the government authorities were compelled to adopt stringent measures to put a stop to it. We have here evidence that the demand for very high tensile strengths at early ages, while intended to guarantee an especially good material, really results in an inferior one being put on the market.

These, then, are some of the reasons why we may, perhaps, conclude that the excessively high tensile strength requirements which some specifications contain are not warranted by the advantages which the cement that meets them offers for practical engineering work. Lacking conclusive proof that cements which are very strong at early ages are not more durable than those which test lower, this is probably all that we are justified in concluding. There is great need for definite experimental information upon this point in the shape of a series of long time tests of various cements having very low, very high and medium strengths in short time tests. Such tests if sufficiently comprehensive would do very much to settle the question which we have briefly discussed here, and some of our cement laboratories would perform a valuable service to engineers in carrying them out. Unless such enormous strengths as 500 lbs. or 600 lbs. in seven days give correspondingly greater durability and strength, when the cement has been in place for years, they place a useless expense upon both makers and users of cement and should be abandoned in drawing cement specifications for the ordinary run of engineering work at least.

In conclusion we should not be understood as trying to discourage any legitimate attempt upon the part of engineers to secure better qualities of hydraulic cements. We do think, however, that there is a tendency evident in many instances to place too high a value upon tensile strength as the criterion by which a cement should stand or fall as a proper structural material to be used in engineering works, and that this tendency is leading some engineers to make mistakes in formulating their cement specifications. If the same effort which has been expended by engineers and manufacturers to increase the tensile strength of cements at early ages had been expended in developing their reliability and durability the benefit would have been much greater.

◆

LETTERS TO THE EDITOR.

The Patents on the Diesel Motor.

Sir: In your issue of July 21 you give a short abstract of a paper read by Mr. E. Capitaine at Frankfort, attacking the Diesel patent. Having given Mr. Capitaine's statement, you will, no doubt, in fairness, give also Mr. Diesel's reply.

Mr. Diesel advises us that Mr. Capitaine's paper was read in Frankfort on the 20th of April, and consisted mainly of statements and data, which Capitaine had submitted in his suit before the Imperial German Patent Court. In this he moved to annul or largely restrict the Diesel master patent. On the very next day, April 21, 1898, the court, after a review of all this testimony, denied his motion, upheld the Diesel patent and condemned Capitaine to pay the costs. An official copy of this action of the Imperial German Patent Court is on file here and will be gladly shown to any one sufficiently interested in the matter.

Very truly yours,
Diesel Motor Co., of America,
E. D. Meier, Engineer-in-Chief.
11 Broadway, New York, July 25, 1898.

◆

Frog Angles and Crossing Frogs.

Sir: I desire to present some discussion upon the letters on frog angles and crossing frog formulas, published in your issue of June 16. The two points I wish to cover, are, 1st, the useless multiplication of formulas when the case is already fully covered by the standard formulas given for right angled or oblique triangles; and, 2d, I wish to challenge the idea that it is possible to construct a desirable crossing by measuring any part of an old one that is ready to be renewed.

I would like first to call your attention to what seems to me to be the unnecessary complication of the formulas given in Mr. R. S. Ball's method. Would it not be much plainer to say that all cases where a curved track crosses a straight one, with the angle of intersection and the radius of curvature given, can be reduced to a simple case of right-angled triangle, which does not need any other formula than those already given in any pocket manual. Thus, taking the accompanying diagram, the basic factor is the triangle E, F, G, of which G is the point of intersection, F is the center of curvature, and E the point where a line from the center of curvature strikes the center line of the straight track at right angles thereto. You thus have a right-angle triangle with the hypothenuse and one of the acute angles given from which

$F E = r \cos \theta$, adding $\frac{1}{2} g = Fe_1$, substracting the same $= Fe$.

$F A$ and $F C = r - \frac{1}{2} g_1$.

$F B$ and $F C = r + \frac{1}{2} g_1$.

Then, with those two side of the respective triangles given we have

$$\cos A = \frac{Fe_1}{F A};\ \cos B = \frac{Fe_1}{F B};\ \cos C = \frac{Fe}{F C};\ \cos D\ \frac{Fe}{F D}.$$

The actual work will be the looking up of four logarithms, the finding of their differences as indicated, and then searching in the tables for four angles.

Then for the sides,

$$\left.\begin{array}{l} e_1 A = Fe_1 \tan. A \\ e_1 B = Fe_1 \tan. B \end{array}\right\} A B = e_1 B - e_1 A.$$

$$\left.\begin{array}{l} e C = Fe \tan. C \\ e D = Fe \tan. D \end{array}\right\} C D = e D - e C.$$

Angle $A F C = C - A$, of which the tabular arc × $F A =$ side $A C$.

Angle $B F D = D - B$, of which the tabular arc × $F B =$ side $B D$.

This seems to be much more desirable than a long formula that simply amounts to the same thing.

Mr. Wm. Wallace Christie gives methods of solving crossing problems, which seem to me to be specially open to the criticism of starting with an unnecessarily erroneous basis.

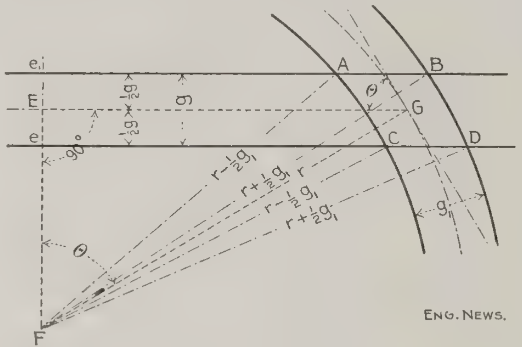

Diagram of Frog Angles.

My experience leads me to believe that it is utterly impossible to secure satisfactory data in the way he describes, namely, by measuring the diagonal of an old crossing and getting the curvature by ordinates. I can hardly conceive of a case where it would be impossible to run out the curves and get the correct angle of intersection, and the better result would most certainly pay for the cost of sending out two men to secure such data, in fact the case would be a rare one where it would cost much (if any) more to get the correct angle than to get the meager information he uses.

Having got the angles of intersection, his Case 1 then becomes the simple solution of right-angled triangles which I have already described, and his Case 2 becomes the solution of a series of oblique triangles whose common side is the line joining the centers of the two curves, the other sides being respectively R and $R_1 \pm \frac{1}{2}$ the gage, according to the point sought. Any formulas that might be needed are surely to be found in the standard formulas given in any of the pocket manuals for these two classes of triangles.

Yours truly,
E. D. Wileman,
Lake Shore & Michigan Southern Ry.
Toledo, O., June 25, 1898.

◆

The Report on the Condition of the Paints on the 155th Street Viaduct, New York City.

Sir: Your editorial of July 21 upon the report on the condition of paints on the 155th St. viaduct shows a lack of ability to grasp either the scope of the report or the character of the tests which is deplorable. Even while you quote from the report the statement that these percentages were carefully reviewed, "so that they might correctly represent the comparative condition of each girder," your criticism is based upon the fact that they do not represent absolute values. Does any intelligent engineer ever make a railroad profile to the natural scale? Yet the elevations are directly comparative.

The purpose in describing in such detail the method of examination was to enable any engineer to make his own deductions; and it was not expected that a test of six months' duration would be considered final or conclusive. You suggest the advisability of waiting two years before forming any conclusions. You seem to be unaware that this structure is liable to be repainted at any time, since the original invitation of May, 1897, from the Department of Public Works, made reference to "painting the vialuct next year." It is to be hoped that this repainting may be deferred, but we have no assurance that such will be the case. Although the test is of such short duration, there are two facts which are as definite now as they ever will be:

1. A number of the paints have failed absolutely to protect the metal from sulphur gases.

2. The carbon and graphite paints prove generally efficient for this purpose.

You suggest that "it would be an excellent idea for the Committee of the American Society of Civil Engineers, which has in charge the subject of paints on metal work, to make a thorough examination and report." Would it not be a still better idea first to appoint such a committee, as none exists at the present time? Furthermore, there is no probability that a committee of the Am. Soc. C. E. could ever make such a report. Neither red lead nor iron oxide in pure linseed oil have been tested here, yet these two paints have long been in general favor as a protection for iron. All the paints used in this test were patented compounds.

Your criticism of my method of giving percentages may be left to the individual judgment of your readers. If a girder 69 ft. long and 9 ft. deep cannot receive a general inspection from a point 12 ft. distant, the results sought are not such as should be desired in a report of this character. You may find difficulty in counting the rust pimples on a girder, but for the purpose of a report of progress you may select several points of view, each equally advantageous for every girder, make a separate list of percentages from each standpoint, and by computing the averages obtain results which are fairly accurate and truly comparative. While it may be true that no two engineers would give exactly the same percentages, it is also true that engineers following this method of procedure would not differ materially on the comparative condition of these paints.

Your editorial quoted the paragraph describing the method of procedure. Why not quote the next paragraph as follows:

> After completing the examination and recording the results, the kinds of paints used for each girder with the number of coats and comparative rapidity of drying were obtained from Mr. M. E. Evans, C. E., under whose direct supervision the girders were cleaned and the various paints applied.

This is the key to the whole report. The stipulation with which I undertook this examination, was that I should have no previous knowledge of the different kinds of paints on the several girders. Did your examining editors take the same precaution?

I regret that any of your advertisers should have been injured by your publication of the report.

Yours truly, Henry B. Seaman.
40 Wall St., New York city, July 25, 1898.

(Mr. Seaman's statement in his original report was that the figures he gave represented the percentage of the surface of each girder which was free from rust. We took this to mean that they were intended to represent absolute values; but the first paragraph of the above letter seems to contradict this.

We were in error in supposing that the committee of the Am. Soc. C. E. on "Paints for Metal Work" had already been appointed. A resolution favoring the appointment of such a committee was adopted at the annual meeting last January, and was referred to the Board of Direction in accordance with the Constitution. The Board will report its action on the matter, we suppose, to the meeting at Detroit this week.—Ed.)

◆

Gould's "Arithmetic of the Steam Engine."

Sir: I have just read your review of my little book, "Arithmetic of the Steam Engine," in the June 2 number of Engineering News, having missed many numbers during my absence at army headquarters in the South. Since you therein charge me with several errors and inaccuracies I presume that you will allow me to attempt to clear myself of these charges.

Let me first say I am glad that one of the charges which you make against my book is its brevity, because I consider that to be one of its chief merits. It would fail utterly of its purpose if it were not brief. But to turn to the more serious faults which you allege against it.

You say my assertion that the quantity of heat contained in a body is "its temperature into its weight into its specifit heat," is incorrect because it does not apply to superheated steam. I think this criticism is hardly fair, especially since I state, in the chapter on steam, what the quantity of heat contained in steam is.

You next take exception to my statement that, per Porter's tables, the sensible heat of steam is always a little higher than its temperature. Seeing that Porter's tables are conveniently bound up for reference in the back of the book, I can only express my surprise that you did not verify the correctness of my assertion by glancing at the figures in columns two and three of these tables.

You then say, referring to another of my statements, that you see, for the first time, horse power defined as the engineering unit of virtual velocity. Very good. But is not the definition correct, all the same?

Referring to my remarks on momentum, which I can assure you were not hastily penned, you object to the clause which says "Momentum represents the stored or acquired energy of weight acting through time," on the ground that it might be construed to show that a body at rest could acquire energy by acting through time. I reply: Scarcely, for I had just defined momentum as "quantity of motion," and explained that the momentum of a body moving with a certain velocity is equal to its weight into the time during which it would have to fall under the influence of gravity in order to acquire that velocity. The paragraph should be read in its entirety. If, in the formula which I give for momentum, velocity is made equal to zero, as occurs when a body is at rest, then the resulting momentum of that body becomes also equal to zero, as it should. To prove that I am wrong you then give the example of a 10,000-ton ship acted upon by a weight of 1 lb. for a period of 100 seconds. To which I reply that your data neither suffice for the use of the formula which I give nor conform to my definition of momentum as quantity of motion, and therefore your example proves nothing.

Your final remarks on my observations upon vis viva do not seem to call for any reply because I do not find that they seriously challenge my assertions.

I cannot agree with you that I should have done better had I used the words of Rankine and of Clark instead of my own. I grant you that their words are infinitely better than mine, but I do not think I would have been justified in rehashing them in a volume purporting to be written by myself.

I cannot but regret that you have conceived it to be your duty to search only for defects in my little volume. I think if you had read the book more dispassionately you would have detected some of the merits which other competent authorities have found it to possess.

Very faithfully yours, E. Sherman Gould.

Yonkers, N. Y., July 14, 1898.

(We give space with pleasure to Mr. Gould's defence of his book, but must reply to one or two of his statements. We find the term "sensible heat" in a column of the steam tables in the back of the book, said to be taken from Porter. We have not Porter's book at hand to refer to, but it also has made a slip if it uses the term "sensible heat" in this way, for the thing signified is not "sensible heat," but the total heat (above 0° F.), measured in B. T. U. in 1 lb. of water of the temperature given. The term "sensible heat" we take to mean heat that is perceptible by the senses, to give it any other or arbitrary significance appears to us a misuse of language, but it may be that Mr. Gould is not the one originally responsible for this.

"The engineering unit of virtual velocities is the horse-power." Is this a correct definition? We think not. As stated by Mr. Gould, the equation of virtual velocities obtains when $P V = P_1 V_1$, in which P and P_1 are the weights of two bodies, and V, V_1 their respective velocities. According to Coxe's Weisbach, p. 209: "If a system of forces which act in a plane have a motion of translation, then the work done by the resultant is equal to the sum of the work done by the components," and this statement is given as the "principle of virtual velocities." Rankine's Applied Mechanics, p. 479, defined the "principle" as "the name given to the application of the principle of conservation of energy to the determination of the conditions of equilibrium amongst the forces applied to any connected system of points." We fail to find in these definitions any suggestion that there is such a thing as a "unit of virtual velocity," still less that a horse-power, which is the unit of rate of work, or the foot-pounds of work done in a minute divided by 33,000 can be such a unit.

"Momentum is weight into time." Mr. Gould satisfactorily explains what he means by this expression, and we now understand that the momentum of a ship moving at the rate of 1 mile an hour is equal to its weight multiplied by the time during which it would have to fall under the influence of gravity in order to acquire that velocity; but it would have been better, it seems to us, to give the term momentum the usual definition, the product of mass, or weight $\div$ g, into velocity. His statement that, momentum represents stored energy, however, is still inaccurate, for momentum is $m v$ and energy is $\frac{1}{2} m v^2$.—Ed.).

Notes and Queries.

Heating Surface per Horse Power (Correction).—In the abstract of Mr. M. C. Huyette's paper on "Boiler Furnaces for Steam Power Installation," on p. 47 of our issue of July 21, 100 sq. ft. of heating surface per horse power is a misprint for 10 sq. ft.

F. M. T. asks our authority for the depths of harbors of the United States given in our editorial of July 21, p. 41.

We compiled the table from "Bulletin No. 36, U. S. Coast and Geodetic Survey. Table of Depths of Channels and Harbors, Coasts of the United States," issued in 1897.

A YEAR'S PROGRESS IN ENGINEERING.*

It was formerly the duty of the President to give a summary of the progress in engineering during the preceding year. This duty does not now exist, but, inasmuch as a number of my predecessors have selected other subjects for their annual addresses, I have thought it proper to return to the old practice, although the engineering field has now become so large that a short paper can give but a very incomplete sketch of the subject.

Railway Construction.

The mileage of railways built in the United States in 1897 (2,108 miles) is not extensive. It hardly varies from the mileage built in 1896 or 1895, is a little lower than that of 1894, and far below that of 1890 to 1892, and earlier years. Of the separate states, California leads with 221 miles. Canada returns 395 miles, and Mexico 367 miles. In Canada the Canadian Pacific Ry. has done a vast amount of work in converting temporary into permanent work, and in reducing the grades in the Rocky Mountains; and improved transportation facilities for the grain trade have been inaugurated by the construction of the Ottawa & Parry Sound Ry. extension to Parry Sound on Lake Huron.

In the last fiscal year 714 miles of Indian railroads were opened, and the total mileage now is nearly the same as that of the United Kingdom. In Japan the progress is marked. In March, 1897, the passenger traffic was reported to be 21.2%, and the freight traffic 15.1% larger than during the previous fiscal year, and further development on a larger scale is contemplated and partly begun. In China, while at present there are only 300 miles of railway, additional lines, involving a much larger development, are now projected, under the auspices of several European nations. The great Trans-Siberian Ry. is advancing steadily toward its eastern terminus. In Africa the Congo Ry., from Matadi to Stanley Falls, constructed by Belgian engineers with Belgian capital, is expected to be opened before the end of this summer, and the Bulawayo Ry., in South Africa, was opened a few months ago. Even in Abyssinia a line from the coast to the interior of the country is projected.

Improvements in Railway Operation.

In the United States, while the actual amount of construction has not been large, the general tendency has been toward an increase of speed and safety, which has been attained by the introduction or improvement of such devices as heavier rails, the air brake, the interlocking system of signals and the strengthening of cars. The block system of signals is now so common that it is difficult to realize at the time of the World's Fair, in 1893, only one line of railway in the United States was fully provided with it.

The equipment in general is being perfected, heavier locomotives are being built, and the compound locomotive is being slowly introduced with promise of success. Efforts are especially being made to secure uniformity in mechanical devices. The result of the labors of a committee of this Society has had much to do with the introduction of uniform rail sections, and you will be called upon here to decide whether a similar committee shall be appointed for the study of a uniform type for rail joints. Notable progress toward the abolition of grade crossings has been made, in and near a number of cities.

In recent years extensive and more commodious terminal and union stations have been built in large cities; a conspicuous instance is the Southern Union Station now being built for a part of the railway system which terminates in Boston.

Street Railways and Electric Locomotives.

Within a few years the development of cable and electric railways has been phenomenal in the United States and all over the world. The advent of the trolley car has revolutionized travel, and affected the movement of population in the neighborhood of large centers. In some instances, electric traction has begun to compete with local steam railways, and the cheap fares made possible by its economical installation have placed travel for business or for pleasure within the reach of the poorest. Compressed air has also come to the front; as an instance of it, compound air motors for certain lines of street cars in New York city are now contracted for.

Among the successful examples of electric propulsion may be mentioned the Baltimore Belt Line of the Baltimore & Ohio Railroad; the electric high-speed suburban service about Cleveland, including six different lines and covering long distances, and many others in various parts of the country; the Chicago elevated railways; the proposed systems of rapid transit in New York and Boston; the Boston & Nantasket branch of the New York, New Haven & Hartford R. R.; the third-rail electric system between Berlin and Hartford, Conn. We may note here that the question of rendering the third rail innocuous after the passage of each train is apparently solved.

In England the Metropolitan Ry. Co. and the Metropolitan District Ry. Co. have already acquired the necessary parliamentary rights to adopt electricity as their motive power, and are said to be waiting until the new Central London Ry., the greatest electrical enterprise in England, shall have been in operation. In France, the proposed new terminal of the Orleans Ry., consisting of 2½ miles of underground railroad in the heart of the city of Paris, is an important enterprise.

Canals.

One of the most important questions in the United States is that of the connection between the Great Lakes and the Atlantic. A United States commission is now at work on a report as to the best plan to be recommended. Opinions differ materially as to the advisability of building from the Lakes to the Atlantic a deep ship waterway or one of smaller dimensions. In the meantime the state of New York is at work increasing the depth of the Erie Canal to 8 ft.

At Sault Ste. Marie, in 1897, the traffic of the ship canal amounted to 18,954,000 tons, a tonnage much larger than that of the Suez Canal. The Montreal, Ottawa & Georgian Bay Ship Canal, by way of Georgian Bay and the Ottawa River, which, it is said, will save 1,100 miles between Chicago and Liverpool, should be mentioned.

The recent naval operations connected with the present war with Spain have revived the question of the American Isthmian canals. The feasibility and cost of the Nicaragua Canal are now being investigated by a United States Commission. The report of a previous commission concluded that the canal is feasible, but at an estimated cost higher than was reported by the original promoters of the enterprise. In the meantime, the new Panama Canal Co. is at work on the Isthmus, and is now making a further engineering study of that work, with a view of deciding whether the undertaking can be profitably pushed through. If the report is favorable, an effort is to be made to find the necessary capital for the completion of the canal. In both cases it appears that construction was begun without sufficient data, and that the most serious engineering question to be solved is the proper and safe disposition of the freshets caused by the great rainfalls of the wet season. The necessary investigations are now being made.

In France, the proposed canal from the Atlantic to the Mediterranean has been finally abandoned as too costly. It is reported that the Suez Canal is to be deepened. In Russia, a ship canal, to join the Baltic and Black Seas, is to be begun next spring. Of the 1,080 miles, the reported length of the canal, 875 miles are to be in canalized rivers, leaving only 125 miles to be excavated. In Italy, the regulation of the Tiber River is nearly completed. This is an important work, the total cost being estimated at $21,000,000.

The following statistical figures as to the cost of large canals in various parts of the world are thought to come from a reliable source:

Name.	Length, miles.	Years building.	Total rock & earth, cu. yds.	Cost.
Suez	66	9	80,000,000	$100,000,000
Corinth	3.7	12	15,220,000	15,000,000
North Sea	61.5	8	....	37,440,000
Chicago	40.6	5	40,000,000	25,300,000
Manchester	35.5	6	53,500,000	77,000,000

Bridges.

In the construction of bridges, the last few years have seen a further development in the designs of structures for large spans. The United States government has required the building of such bridges, up to 1,000 ft. span, over the Ohio, Mississippi and other rivers. The necessities of the traffic of New York city have given renewed impetus to the designing of suspension bridges of unprecedented span, and have caused the introduction of novel details, made practicable by recent improvements in the manufacture of steel. The perfection of the methods for erecting long and high-span trusses has also rendered these operations much more satisfactory as to cost, and as to the important element of the time necessary to carry them out. The recent reconstruction of the Niagara Falls Bridge is a conspicuous instance of the best modern engineering in that field, and the new East River Bridge will probably be the prototype of others.

The various designs for a much larger suspension bridge over the Hudson River are familiar to you, and have carried the possibilities of bridge building much beyond long-accepted limits. The famous Victoria Bridge, justly considered at the time of its construction a bold and novel undertaking, has outlived its usefulness, and is being replaced by a modern steel structure of 20,000 tons (with 24 spans of 254 ft., and one of 350 ft.), which will be far lighter and cheaper, although of greater strength, than the original bridge.

There has been a tendency in recent years to return to the construction of stone arch bridges, wherever local conditions as to cost of foundation and length of span have justified the generally larger outlay necessitated by this class of more permanent structures. In this connection, the recent introduction of the three-hinged masonry arch must be noted. The Melan arch, of which many examples have been presented in recent years, has pushed to the front the principle of the mixed construction of masonry and metal. Although, owing to the changes of form produced by varying temperatures and by the internal movements due to the behavior of masonry before it is entirely set, there may remain some doubt as to the perfect homogeneity of this class of construction; success has, undoubtedly, been achieved in many cases, but time alone can give final sanction to the wide adoption of structures of this class. The arch bridge at Topeka, Kan., said to be the largest of that description, costing $150,000, and containing only 140 tons of steel, is a conspicuous instance of this method of construction.

---

*Slightly condensed from the address of President Alphonse Fteley at the Detroit meeting of the American Society of Civil Engineers.

High Buildings.

When the modern high building of skeleton steel with masonry walls was first introduced for business purposes, some doubts existed as to its permanency. Many new problems as to the stability and fire-resisting properties of such buildings presented themselves, but the complicated questions of their equipment, including untried methods of carrying passengers, and of supplying water, sewerage, heating, ventilation, etc., appear to have been solved satisfactorily. High buildings have been erected on various kinds of foundations. In many cases solid rock has been reached at great depths, and compressed air has been resorted to in the building of the main supports; in others, the weight has been so distributed over uniformly yielding materials as not to tax them beyond practical limits. Frequently, where the resistance of the ground was not uniform, the adaptation of various parts of the structure to the weight to be supported at each place taxed to the utmost the ingenuity of the builders. In certain cases, mechanical devices have been introduced for the purpose of meeting possible irregular settlements. The distribution of weight on yielding foundations has often been accomplished by clusters of steel beams imbedded in concrete. At times, when the foundations of proposed structures extended below the lowest point of the foundation walls of neighboring buildings, it was necessary to support the latter, and at the same time not to interfere with the operations of construction, generally conducted on restricted areas; this result was accomplished by the introduction of novel and ingenious devices. The necessity for reducing the weight of buildings has resulted in the reduction of the masonry part to a minimum by the adoption of floors which possess lightness and strength as well as fireproof qualities. The rapidity and ease with which these extensive buildings are erected without extraordinary impediment to travel in crowded streets is remarkable.

The future of the high building, with its many parts out of reach, and without possibility of examination and maintenance, is now difficult to predict. Several modern fireproof buildings have stood well the test of fire, but no great conflagration has occurred to show what the results of such a contingency would be. In a recent earthquake on the Pacific Coast, modern high buildings are reported not to have suffered.

Outside of constructive possibilities, however, other questions which may have an important bearing on the future of high structures present themselves: Their influence on real estate values, on the growing accumulation of population in the business districts, and on the problems of water-works and sewerage. Should the erection of high buildings extend more and more, the sanitary condition of the people passing a part of their life in districts thus built up would become a serious question, and one which should be taken in hand by the proper authorities. The height of these buildings is now, in many cases, too great, and if this style of construction is to go on it is most probable that it will be limited everywhere by law, as has been done in several cities.

Harbor Improvement.

The constantly increasing size and draft of large vessels for commercial and military purposes make it necessary in many cases to deepen harbors, and also enhance the cost of docks, dry-docks, and of all structures connected with river and harbor works, the size of which depends upon the depth of adjacent waters. For the purpose of facilitating navigation in rivers and harbors, great improvements have been made in dredging apparatus, the capabilities of which have rendered possible excavations which would have otherwise required too much expenditure of time and money. In this country the dredging operations on the Mississippi River have reached an unexpected development and success.

The great docks of Duluth and Superior, recently built to accommodate the large grain crops of the two Dakotas and part of Iowa and a great amount of iron ore, coal and other products, the new Liverpool docks and the recent dock improvements of Dunkerque and Calais, are examples of modern designs in that line. In this connection may be mentioned the new breakwater, 20,000 ft. long, under construction by the Government at Buffalo, which is the largest on record.

Public Water Supplies.

The number of places in the United States now possessing a public water supply, whether under public or private ownership, is nearly 4,000; but, while systems of works increase in number and importance, it would seem that we lack in this country the faculty of properly regulating them as regards the quantities to be furnished. In large cities, with some exceptions, the per capita consumption is increasing, and in several of them the amount consumed attains absolutely inordinate proportions, although, in some of them, every gallon of it has to be pumped. The old cry that water in our communities should be as free as air is heard from people, who from their intelligence and business habits should know better, and the taxpayer does not stop to think of the result of extravagance in water consumption. More water means more and larger pipes, more capacious reservoirs, more pumping stations, and, in many cases, new sources of supply, with the attendant large outlays necessary to procure them. It also means increased risks in some cases, as in New York, it becomes a problem to locate water pipes properly in already crowded streets. That there is a large waste of water is admitted by all, but the means of checking it are not generally applied. Objections are raised as to a more extended system of making consumers pay for the amount of water actually consumed, and clumsy and inaccurate methods of estimating the amount and value of the water used are resorted to, which not only would not be tolerated for the sale of other commodities, but would be considered absolutely ridiculous.

The consequences of excessive consumption of water are ominous. Take the case of New York: In 1890 its new aqueduct was put into service, the consumption then being 110,000,000 gallons per day. After nearly eight years, the average for 1897 was 230,000,000 gallons per day, a per capita rate of about 115 gallons. At this rate the new system of water supply begun over ten years ago and constructed at a very large cost will soon be insufficient in a dry year, and new sources will have to be developed at a much greater cost.

The large cities of this country, which, located on the sea coast, have no fresh water within easy reach, have generally taken too great risks in the matter of their water supply, and it is to be wondered at that no harm has resulted from this policy; those especially where the density of the population is great should have more than one system of water supply, and it is to be hoped that this view of the subject may be adopted.

Water Purification.

With the advance of sanitary science the need of purer water has been felt, and efforts have been made in many directions to improve public water supplies. Where they are obtained by impounding river waters in storage reservoirs formed by damming the streams, great inconvenience has been felt from offensive tastes and odors, generally produced by the development of microscopic vegetation. Efforts have been made to improve the gathering grounds and the reservoirs, and in a number of cases, especially in and about Boston, the soil, down to the underlying sand and gravel, has been removed at a large expense, to the great benefit of the impounded waters. In cases where the same inconveniences have been experienced in underground waters pumped into reservoirs exposed to the light, a notable improvement has been produced by covering the reservoirs.

Much attention has been given in late years to the study of filtration processes. Thirty years ago, an eminent member of this Society and one of its late Past-Presidents, prepared, for the benefit of the St. Louis Water-Works, a report on "Water Filtration," which, for many years, was the most valued text-book on the subject. It was then thought, and it was so maintained for many years, that hardly any chemical action took place in the filtering of water, and that the main function of the filter was to retain the particles suspended in the water, very little action taking place on matters contained in solution. Little was known of the influence of filters on bacterial life. Within recent years, however, especially through the efforts of the Massachusetts State Board of Health in conducting at the experimental station at Lawrence its well-known series of experiments, results have been obtained which have revolutionized the theory of water filtering. Radical chemical and biological changes have been found to take place in the operation of filtering, and bacterial life has been recognized as the most potent instrument for the conversion of organic matters into mineral compounds, while it operates at the same time as an agent of almost complete self-destruction, provided, of course, that the construction of the filters, the selection of the filtering materials used and the subsequent care of the apparatus are such as to properly carry out the results indicated by the laboratory experiments.

A number of different materials have been recommended and used as filtering media with varying success; the most extensively used have been sand and gravel. Sand filters have been in use in Europe for many years, long before the full measure of their usefulness was known, and the modern applications of the system have been highly instructive. We all recollect the striking results of the differences in mortality in Altona and Hamburg during the recent epidemic of cholera, when the first-named city, with a water supply polluted by sewage, but filtered, showed only sporadic cases, while in Hamburg the water supply, less polluted, but not filtered, was recognized as the cause of the heavy mortality recorded. No large systems of what may be called gravity sand filters exist in America, but important communities have been recently and are now making extensive experiments with a view to building some, and in one instance at least, in Albany, a system of filters on a large scale is now under construction.

In mechanical filters, in which various filtering substances, mainly sand, are used, coagulants are generally used to eliminate a large portion of the organic and other matters contained in the water, and sufficient pressure is applied to force the water through the filtering medium so as to cause a flow of water larger than through gravity filters, per unit of area. They have been used for years and have recently been so perfected as to be reported by their inventors as capable of successfully competing with gravity filters in cost and in efficiency. Two very important series of experiments have been made by large cities to investigate the merits of the mechanical filter. Further developments and added experience will evidently be needed to decide the question. From reports made by capable experts in behalf of communities in search of advice for the purpose of constructing filtering apparatus, it appears that the choice between the two systems, in many cases, must be determined by local circumstances, depending mainly on the cost of the filtering materials and on the quality of the water.

The public appears to realize now, more than ever, the desirability, if not the absolute necessity, of procuring purer water, and the close connection between pure water and improved public health is better understood by public bodies. From an economical standpoint alone, when considering the commercial value of each human life, the saving effected by diminishing the mortality would represent a large capital.

Water Pipes.

Construction has been favored by the decreasing price of iron and steel. The price of cast-iron pipes, especially, has never been so low as it is at present. Steel riveted pipes, for the conveyance of water from the source of supply to the point of consumption, in recent years have been introduced more liberally in the East. For long distances, with large diameters, under heavy water pressure, especially when few connections have to be used on the way, these pipes are as much superior to cast-iron pipes as the steel substitute is to the old cast-iron tension member of a bridge, and it is not doubted that they will be ultimately used to the exclusion of others, but, unfortunately, although similar pipes made of wrought iron have been successfully used for years on the Pacific coast, and elsewhere, it cannot be said that the coatings used to preserve the metal from oxidation are entirely satisfactory. The rivets used for fastening the pipes and the lapping joints impede the flow to a certain extent, and a pipe has been devised, the fastenings of which are entirely outside and provide the pipe with a smooth bore. The great improvement in steel-welded pipes of large diameter will also remedy that defect to a large extent. An order is reported of several thousand tons of welded pipes to be made of Siemens-Martin mild steel, 24 ft. long and 42 ins. in diameter, for the Birmingham Water-Works. The possibilities of steel pipes are well illustrated by the proposition to convey a much-needed supply of water, of 5,000,000 gallons per day, to a mining district of Western Australia, by means of a pipe 30 ins. in diameter and 328 miles long.

Dams and Reservoirs.

The construction of water-works and of irrigation works has rendered necessary, in recent years, the erection of many dams for the impounding of water, a number of them being of great height. Few new principles of construction have been introduced, but improved methods for the building operations have been resorted to, thereby reducing the ultimate cost and the time necessary for the completion of the structures.

The solid stone masonry section on the general plan originally introduced by the French engineers, has been accepted in many places; the general practice now being to use large stones with the necessary filling of spawls instead of the uniform small-stone masonry, formerly adopted and even recently recommended by eminent engineers. Elsewhere, concrete masonry has been adopted, this course being generally indicated by local circumstances, such as the high cost of, or even the lack of, stone in the vicinity. In recent instances of concrete dams slight vertical cracks have developed which have been less frequently found, if at all, in well-built stone masonry, owing probably to the more thorough bonding of the mass by means of the interlocking of heavy stones. In the western part of the United States rock-filled dams have been built, the imperviousness of the structure being procured by the construction of core-walls, by the building of a timber lining on the up-stream side or by other devices. The earth dam continues to be universally used; parts of India and of the United States showing recent instances of this mode of construction for high dams, mostly with the aid of puddle, or masonry and concrete core-walls. A peculiar core, formed of thin sheet iron, used in connection with a recent rock-filled dam in California is worthy of notice, if not of imitation.

It is to be regretted that theoretical calculations cannot be accurately applied to the computations of the stability of dams. The distribution of strains through such masses is not well known; moreover, the diversity of the materials used; the unavoidable lack of uniformity in the labor employed, the different times of the year in which the work is performed under varying temperatures, are all elements which cannot be accurately analyzed, although they can be provided for by the introduction of the too often necessary margin of safety. Experience must here come to the rescue of the designers, and dictate the necessary precautions to be used in accordance with known precedents. Especially is this true of the designing of earth dams, for which, in almost every instance, a careful study must be made of the particular materials at hand for construction.

The uncertainties just alluded to have been eliminated in the design of a dam of moderate size, the building of which has been recently reported. It is formed of steel columns and struts reposing directly on the bottom of the valley, the up-stream side being formed of steel plates rendered water tight by the application of a bituminous coating. It is possible that in many instances the cost of such a design would be too high for practical purposes, and some of its features may not be unobjectionable, but it is noteworthy.

Many dams of importance have been recently constructed or are in process of construction or of preparation. The Periar dam, in the Province of Madras, 173 ft. high, was completed in 1893, under exceptional difficulties, for irrigation purposes. The dam built for the water-works of the City of Remscheid, Germany, was also recently erected. In the masonry dam of La Tache, in France, the old French practice of using such small stones only as two men could carry has been continued, although convenient quarries were at hand. The new Croton Dam for the water-works of New York, to be of masonry and earth work, a structure of great height and involving the laying of over 600,000 cu. yds. of masonry, is well advanced.

In the states of California and Arizona especially a large number of dams, mostly for irrigation purposes, have been recently completed or are being erected. The Upper and Lower Otay dams, one of them provided with a thin steel core, are important in size. Several masonry dams in Arizona, of great height, may be mentioned; one of them to be 250 ft. high above foundation, and to form a reservoir of the enormous capacity of 1,020,000 acre-feet. La Mesa dam, in California, was built with materials transported and deposited in place by flowing water, by the process known to miners as "ground sluicing." Another, to be 130 ft. high, is expected to be built by the same method. The Louisa Needle Dam, built for the regulation of the Big Sandy River, Ky., recently completed, is remarkable from the fact that it sustains a head of water which considerably exceeds that supported by any other dam of the trestle or wicket type yet constructed.

As the needs of water supply and irrigation call for higher dams, the reservoirs formed thereby are obviously increasing in size, and figures are now being reached as to reservoir capacities, which recall the size of the great ancient reservoirs, the knowledge of whose existence has been transmitted to us by tradition, if not by history. The idea of the restoration of the great compensating reservoirs of the Nile, spoken of some time ago, does not appear to be any longer entertained, but the erection of two dams across the river, with a proposed storage of 266,000 million gallons, for the purpose of regulating its flow, is now being seriously contemplated, if not already started. The system of compensating reservoirs for the Mississippi Basin is well under way.

Sanitary Engineering.

The construction of sewers keeps pace with the general development of municipal engineering; the second part of the metropolitan system of sewers for Boston and the neighboring cities and towns has been practically completed; the great Drainage Canal of Chicago is approaching completion, and, in connection with it, intercepting sewers of large diameter are being built under peculiar difficulties; many other systems of sewers are in process of construction or in preparation.

The question of the disposal of the sewage from cities and towns, in view of preventing the pollution of streams, is especially occupying the attention of municipal engineers. Many reports recently made on the subject have attracted the attention of the profession, and in several states commissions have been appointed for the purpose of studying this problem in reference to the welfare of adjacent and neighboring communities. Those who are studying these questions, however, are much hampered by the lack of proper laws, and, in many cases, special legislation must be procured. A commission has been recently appointed in the state of Connecticut for the above-mentioned purpose, and the state of New Jersey is now attempting to procure the necessary legislation in order to properly define the rights and duties of the various communities interested in the purification of the Passaic River, now much polluted by sewage.

The practical applications of the various systems of disposal of sewage are comparatively few in this country, although new works of that description, on the principle of irrigation, filtration and chemical precipitation, have been inaugurated within the last few years. The chemical precipitation system of London, with its production and disposal of 2,000,000 tons of sludge in 1897, remains the largest exponent of that class of work.

Paris completed in 1895, by means of the Acheres Aqueduct and Park, a large addition to its irrigation system which disposes to-day of one-half of the total flow of the sewers of the city, and Berlin has so added to its irrigation fields that their total area is 20% larger than that of the city.

Much attention is being given in many directions to the disposal or utilization of the waste of large cities. Cremation processes appear to be looked upon with increased favor as being the more economical; great advance has been made in that direction in Hamburg and Berlin. It would seem that the greater amount of coal wasted in this country should make this process more successful. Reduction processes of various kinds have met abroad with a moderate degree of success. Several important plants have been and are being built in the United States; they have not been an entire success so far, and may be said to have hardly passed the experimental period.

Tunnel Construction.

The construction of recent tunnels for railroads, waterworks, sewers and other purposes shows marked progress. Tunnels are driven at a more moderate cost, in less time, and difficulties are surmounted with greater ease. In crowded streets, underground building operations, at times very near the street surface, have taken place with least injury to buildings and without interruption to traffic or danger and inconvenience to citizens. Parts of the London Metropolitan Railroad, the underground railroad under the Boulevard St. Michel in Paris, and the partly completed subway of Boston, are conspicuous instances of tunnel operations conducted in accordance with the most recent methods. By similar means, one of the main French railroad lines is to transfer its terminus from the outskirts of Paris to its most central part. The proposed underground Rapid Transit system of New York city may soon give another illustration of the possibility of building conveniently and rapidly through crowded streets. With the perfected driving shield, the use of compressed air, and the methods of excavation recently used, few difficulties would appear to be insurmountable.

The project of the Simplon tunnel through the Alps is coming to the front again, and although not yet fully financed, construction is soon expected to start. It is 15 miles long, and, notwithstanding its great length, is expected to require one-fourth the time devoted to the construction of the Mont Cenis Tunnel, and to cost one-half as much.

With the advent of electric propulsion, the necessity for thorough ventilation in tunnels used for urban transportation does not appear to be considered so important as formerly. It is to be hoped that efforts are to be made to so renew the air in tunnels as to reduce to a minimum, when required, the atmospheric differences between the inside and the outside; the changes experienced in some of the existing structures being sufficient to materially affect public health.

Application of Electricity.

The science of electricity has advanced by such strides that its evolution, it may be said, brings every day new surprises, and that its application to engineering purposes requires the attention of specially trained men. A few words have already been said of the adaptation of electricity to traction. There is, indeed, hardly a branch of engineering in which it cannot be introduced with success.

Its extensive application to the treatment of metals forms the subject of the recent annual address of the President of the Institution of Electrical Engineers of England, and its use in mining operations is being gradually extended. Its universal introduction for the production of power covers a field the limits of which it would be difficult to define. The substitution of individual electric motors in the place of shafting and pulleys is gaining ground, and the improvement thus accomplished has been so important as to already cause a marked movement toward a radical modification in the construction of mills, which can in this way be built more economically and with better conditions as to light and ventilation. On the other hand, flexible transmission by cable (except for traction purposes) is steadily losing ground.

A new impetus has been given to the development of water power plants, which, prior to the introduction of electricity on so large a scale, had lost much of their importance. England, France, Germany and Italy present interesting instances of these modern establishments, and you have heard of some of the largest enterprises in this country and Canada where immense power is now, or is to be, transmitted to great distances.

Engineering Researches.

It is gratifying to state that in many a branch of engineering, experimental researches have been recently made, and are being conducted, and that data of great value are being accumulated. The Massachusetts State Board of Health is continuing its remarkable series of experiments, which have already contributed so much to the development of sanitary science; tests of materials of all kinds have been extended and systematized, and much is expected from the experiments conducted by the American Section of the International Association for testing materials. Mechanical tests of American timber have been made, and are being continued by the Forestry Division of the United States Department of Agriculture, which have already contributed to the subject of timber physics many new facts and experimental knowledge of great value.

Tests have also been recently conducted which throw much additional light on the composition and resistance of fireproof floors and of the bearing power of those in which concrete and steel are united.

In hydraulic engineering we may mention the extensive gaging of streams conducted under the direction of the United States Geological Survey; the continued painstaking experiments of M. Bazin on the flow of water in open channels; experiments made to ascertain the loss of water from reservoirs by seepage and evaporation; extensive tests on the percolating capacity of certain sands and gravels, made by the Engineering Department of the Metropolitan Water Board of Massachusetts; and a number of interesting gagings to determine the flowing capacity of long pipes for the conveyance of water, one important instance of which is to be presented to you at this meeting.

When summing up the conclusions of such experiments the results obtained are frequently represented by algebraic formulae, which are apt to be interpreted as being of a general character, while they give the facts between certain limits which are not always sufficiently defined in the accounts given of the experimental work. Formulae, correct between certain limits, may be grossly erroneous when applied outside of them. To avoid this objection, sometimes a serious one, the custom should be encouraged of publishing, at the same time as the deduced formulae, diagrams of the results obtained, and at the same time the limits beyond which the given experiments do not apply.

The Professional Standing of the Engineer.

We may well ask ourselves whether our profession is recognized by the general public as it should be. The mission we have to fulfil is in no way inferior to that of the other professions. On the engineer depends often the integrity of the capital invested by those who repose their confidence in him, and on the soundness of his designs frequently depends human life, and yet, when the learned professions are enumerated, the engineer is often passed by. This is probably due to the comparative youth of our profession in this country. A generation ago the scope of its usefulness was very much more limited, but the field is being extended at such an increasing rate, and the money invested in engineering enterprises of all kinds is correspondingly so much greater, that our profession is steadily gaining in importance and standing. It is obvious that we can all contribute to that result by our individual professional efforts in our respective fields.

As our work extends, we cannot but feel the need of increased knowledge. In that respect we have much better facilities than our predecessors, as, through professional papers published by engineering societies, and through the engineering press, we can keep abreast of the times, and the educational facilities are much greater. The yearly addition, to the profession, of students who are graduated from engineering schools, favors the dissemination of technical knowledge in many directions, as, owing to their large number they may not all be able to procure purely engineering positions, but must find new openings in the industrial world and in other channels, thereby carrying professional knowledge where it will be found of great value.

While we review the field covered by our profession, it is gratifying to notice that the names of members of this Society constantly occur to us as having had an important part in the advancement of all branches of engineering and in the erection of the most important works executed in America. Moreover, through our foreign members and a few of our American brethren, our Society is by no means a stranger to the engineering practice of the rest of the world. This is as it should be, and as it was foreseen by the founders of the American Society of Civil Engineers; and, owing to its increasing importance, membership in its body will logically become more desirable.

The number of members of all classes is now 2,119, not including over forty applicants now before the Board of Direction. This is a large gain since the beginning of the present year.

When following in the steps of our predecessors in the field, the Institution of Civil Engineers and the Society of Civil Engineers of France, we decided to provide new headquarters for ourselves, the time was very opportune. Convenient as our former building had been, it had become insufficient for our requirements, and greater delay would have caused great inconvenience and detriment. The experience of nearly one year fully justifies the action taken. Our new house has added not a little to the standing and dignity of our body, and the advantage gained amply compensates the increased outlay necessary for its maintenance, a burden that our Society, in its sound financial condition, can well sustain. We have entered a new era of successful life, and, in conclusion, allow me to express the wish that the increasing importance of our profession be the sure omen of the continued prosperity of the American Society of Civil Engineers.

COMPARISON OF RECENT SPECIFICATIONS FOR FINENESS AND TENSILE STRENGTH OF CEMENTS..

In our issue of April 28 we published in tabular form the principal requirements in the specifications for cement formulated by the officers of the Corps of Engineers, U. S. A., for the works in their charge. A similar comparison of the principal requirements for fineness of grinding and tensile strength, embracing both Portland and natural cements and both European and American practice in railway, municipal, bridge and other private work as well as government work, has been brought to our attention by Mr. R. W. Lesley, Vice-President of the American Cement Co., of Philadelphia, Pa., and is abstracted here to supplement the information already given in

TABLE I.—Showing Requirements for Fineness of Grinding and Tensile Strength of Portland Cement in Specifications for Various Classes of Work in the United States.

Specification.	Per cent. passing		Lbs. per sq. in.						
			Neat cement			Mortar, 2 to 1.		Mortar, 3 to 1.	
	2,500 sieve.	10,000 sieve.	24 hrs.	7 days.	28 days.	7 days.	28 days.	7 days.	28 days.
U. S. government engineers	95½	84	131	402	547	150	200	119	189
U. S. lighthouse engineers	95	..	..	383	600	175	250	85	..
U. S. engineers, Navy Department	90*	97†	..	462	..	..	..	..	..
District of Columbia	95	85	..	387	500	125	200	116	166
Average of nine cities.	97	89	161	388	538	158	200	134	201
" six railways	95½	80	115	319	483	123	175	108	150
" six bridges	97	88	119	347	487	142	250	132	200
" three aqueducts	..	80	110	333	400	125	200	132	225§

*6,400 mesh sieve. †3,600 mesh sieve. §One only.

the previous article. This information was collected and compiled by Mr. Lesley himself from authentic sources, and has been published in a pamphlet entitled, "A Summary of Recent Cement Specifications."

The first thing of interest which may be noted in this summary is the close agreement for Portland cement between the averages of the government specifications published in our issue of April 28 and the averages of the government specifications of the leading European countries, including Russia, Belgium, Germany, Switzerland, France, England and Norway, and also 91 miscellaneous specifications for Portland cement taken from a variety of American sources outside of government work. This fact is shown by the accompanying table, compiled from the more detailed figures:

Specification	P. c. passing sieve of		Tensile strength, lbs. per sq. in.				
			Neat cement			3 sand, 1 cem'nt	
	2,500 mesh.	10,000 mesh.	1 day.	7 days.	28 days.	7 days.	28 days.
European govmt	92	(a)	None.	347	528	119	204
U. S. government.	..	..	144	394	536	129	199
91 miscellaneous..	96	85	134	384	528	118	189

(a) 88% required to pass a 5,800 mesh sieve.

A somewhat more detailed summary of the same figures, except that European specifications are excluded, is made in Table I. This table shows quite clearly the variety of sources from which the detailed figures come and also enables a comparison of the practice of American engineers for different kinds of work. Another fact to be particularly noted is the generally moderate requirements for tensile strength, in the 1 and 7 day tests especially.

Turning now to the detailed figures for natural cements we find the following to be the average requirements for fineness of grinding:

Specification.	Per cent. passing 2,500 sieve.	6,400 sieve.	10,000 sieve.
U.S.Engrs. in 24 works	91	85	72.5
District of Columbia...	92.5	..	80
Average of 8 cities*...	93	..	81
" 2 railways.	95	..	..
" 2 bridges..	95	..	..
" total 38 spec.	92	85	79

*62½% is required to pass a 40,000 sieve.

The requirements for tensile strength of natural cements average as follows:

Specification	Lbs. per sq. in.				
	Neat cement.			2 to 1 mortar.	
	1 day.	7 days.	28 days.	7 days.	28 days.
29 government w'ks	38	102	164	*34.5	77
Dist. of Columbia..	75	100	150	50	75
Ten cities	70	134	237	†68	200
Four railways.....	64	105	163	§47	80
3 aqueducts, etc....	60	117	200	‡65	..
Two bridges	55	87.5	185	‡35	70
Average of 51 spec.	63	109	178	‖44	86

*Average of 10 works. †Average of 3 cities. §Average of 3 railways. ‡One structure only. ‖Average of 19 specifications.

There seems to be a wider margin of difference in practice in the use of natural cements, than in the case of Portland cement; but as the cases noted are practically all modern works, we must charge the wide differences of requirement to controlling local conditions.

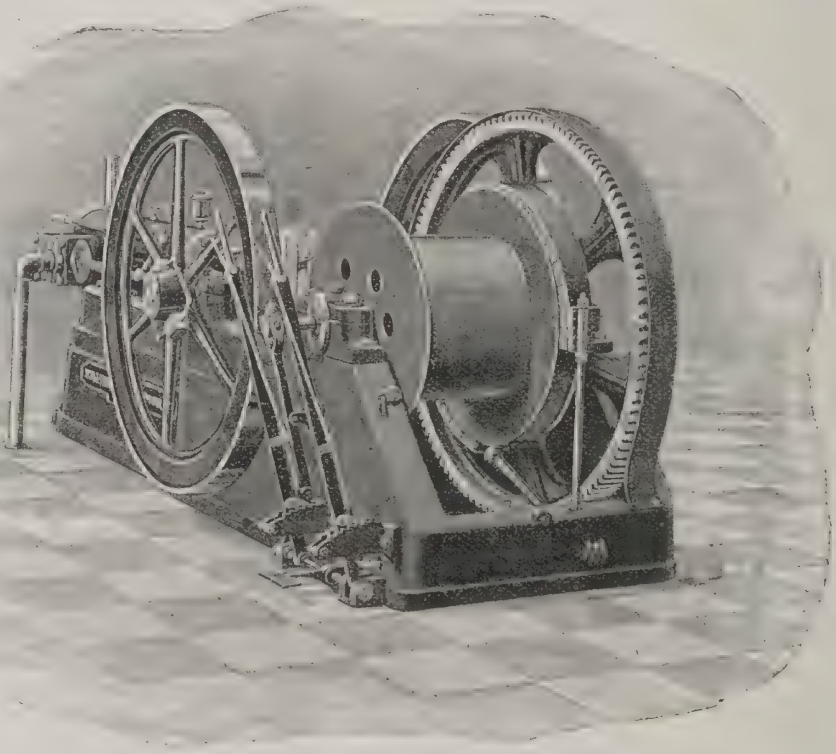
A GASOLINE HOISTING ENGINE.

The accompanying illustration represents a simple and compact gasoline geared hoisting engine, which has recently been placed on the market, in which the entire plant is mounted on one bed-plate. The horizontal cylinder of the gas engine is at the end, the crank shaft and flywheel are at the middle, and the hoisting drum is at the other end.

The drum is loose on the shaft, to which a large gear wheel is keyed, and is gripped to or released from this gear by means of a friction clutch of special form, having a conical surface of wood, which fits a corresponding metal surface in the center of the drum. The clutch is moved along the shaft by means of a vertical hand lever at the side of the engine frame. The foot of the lever, just above the quadrant, is connected to the foot of a rocker arm or lever, to whose upper end is attached the rod of the clutch. This arrangement is shown in the cut, the clutch lever being the one nearest to the flywheel. A special advantage claimed for this clutch is that its action gives no end thrust on the drum shaft bearings. For lowering a load the clutch is released, and the drum is controlled by a hand brake on the end of the drum, this brake being operated by the other vertical hand lever shown in the cut. Both levers have latches engaging with notch quadrants, and are thus locked in whatever position they are set. If desired, the levers can be placed near the head of the mine shaft or level, and connected to the engine by rods or other suitable connections, so that the attendant can see to the dumping of the bucket.



COMBINED GASOLINE ENGINE AND HOISTING PLANT.
Fairbanks, Morse & Co., Manufacturers, Chicago, Ill.

The gearing is well supported, the spur wheel having an outside bearing, while the pinion has an extra bearing between it and the flywheel. Cut gears are used, and the engine and drum shafts have bearings of phosphor-bronze and anti-friction metal respectively. The engine is kept turning over all the time during working hours at its lowest practicable speed, and to hoist, the attendant depresses the pedal near the hand levers, and thus operates a speed changing device by which the speed is at once increased. Gas, gasoline or distillate may be used as fuel, and the cylinder charge is exploded by an electric igniter. A hand starting device is used, which has a small vertical air pump, much like a bicycle tire pump. This sprays a charge into the cylinder, and the charge is then exploded by a hand igniter. With this device one man can start the largest engine.

These hoisting plants are made in six sizes, ranging from 6 HP. to 44 HP., capable of hoisting loads of 1,150 to 6,000 lbs. respectively. They are among the gas engine specialties of Fairbanks, Morse & Co., of Chicago, to whom we are indebted for information respecting them.

ROCK-FILL DAMS IN CALIFORNIA.

A valuable contribution to the 18th Annual Report of the U. S. Geological Survey is a comprehensive paper upon "Reservoirs for Irrigation," written by Mr. James D. Schuyler, M. Am. Soc. C. E. The paper has also been published in a much more convenient form as a separate report. Several of the dams described by Mr. Schuyler have already been illustrated in this journal; but there is an especial interest in the type of rock-fill dams successfully constructed in various parts of the Pacific coast territory to meet existing conditions.

One of the largest of these rock-fill dams, and the first built in California for irrigation purposes, is in the Escondido irrigation district, San Diego Co., and has been in service since 1895, in the irrigation of about 2,000 acres of land. This district is in a valley surrounded by mountains, and the dam is located on the Von Segern branch of San Elijo Creek, at an elevation of 1,300 ft. above sea level and 650 ft. above the town of Escondido. The immediate tributary water-shed covers only about eight square miles; and as this is not sufficient to fill the reservoir with its run-off, the main supply is brought by a conduit from the San Luis Rey River. The conduit taps this river at an altitude of 1,600 ft., and it has a capacity of 28 second-feet and is 15.6 miles long. Of this distance, 67,287 ft. are in ditch, 14,142 ft. in flume and 806 ft. in tunnel. The intake tunnel, 356 ft. long through solid granite, heads in the river 3 ft. below low water level, and its lower end is excavated below grade so as to form a settling basin, in which sand accumulates at the rate of 1,000 cu. ft. daily and is sluiced back into the river. The upper 8,000 ft. of conduit is a wooden flume, supported on the slopes of a rugged canyon, with a general width of 4 ft. and depth of 3 ft. The ditch is 5 ft. wide on the bottom, with side slopes of 1 on 1, and the minimum depth is 3 ft. The total cost of this conduit was $116,328, or $1.29 per foot for construction and engineering, besides 12 cts. per foot for right of way, commissions, etc. This conduit, when running to its full capacity, can fill the reservoir in 60 days, while the drainage area immediately at the dam sometimes yields enough to fill it without this auxiliary.

The general formation is granitic, and at the site of the dam bed-rock was found about 4 ft. below the bed of the creek and nearly level across the canyon. The top soil was carefully removed over the entire base of the dam and construction was commenced immediately upon the bed-rock, which was of the character of disintegrated granite, having harder bowlders scattered through it.

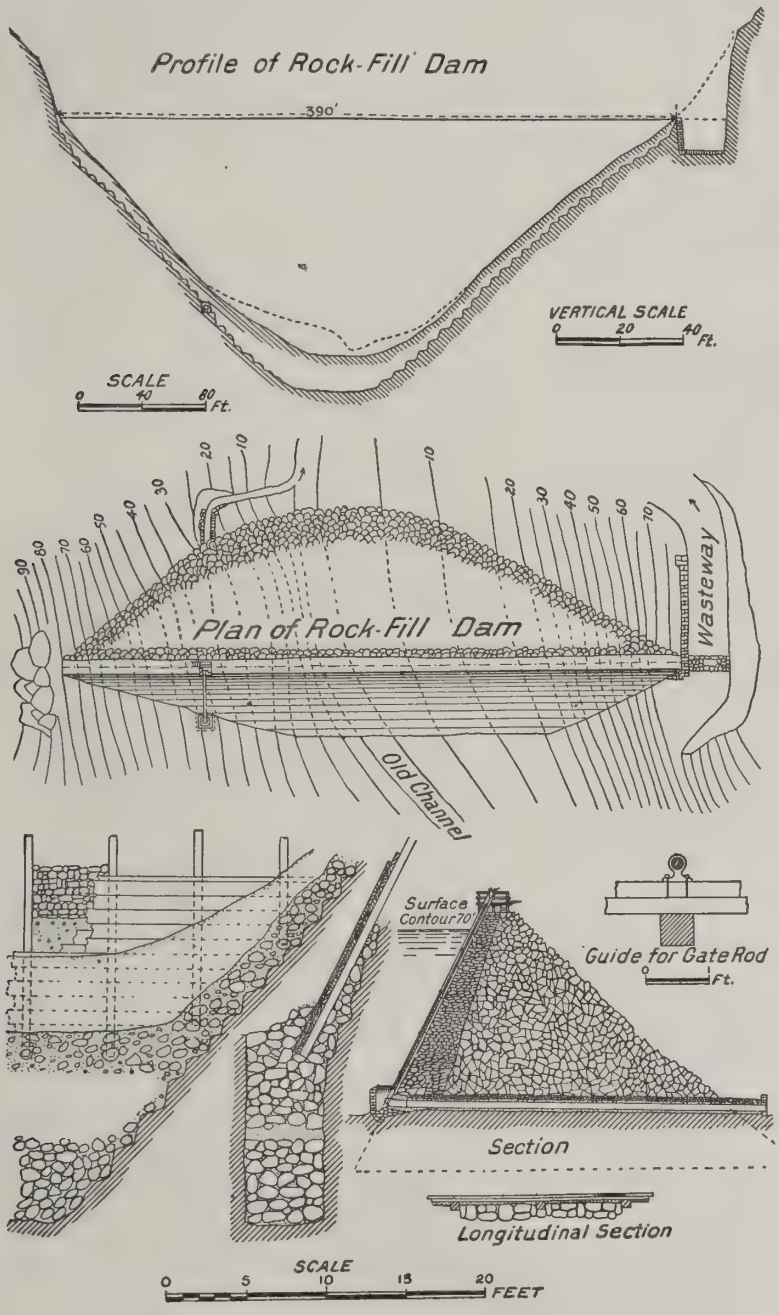
The dam was of the ordinary type of loose rock-fill dam, with plank facing; a type which has given good service in northern California for many years, but is usually regarded as being a somewhat temporary device owing to the perishable nature of the wooden skin depended upon for tightness. The Escondido dam is 76 ft. high, 380 ft. long on top, 100 ft. long on the bottom, and it has a base width of 140 ft. and a top width of 10 ft. A spillway was excavated in the solid rock at the north end, with a width of 25 ft. and its bottom on the 70 ft. contour, or 6 ft. below the top of the dam. This is left open and unobstructed. The slopes of the dam are 1 on ½ on the water face, and on the back 1 on 1 for half the height, with the lower half flattened to 1 on 1¼. After the foundations were stripped a trench was excavated at the upper toe of the dam, from 3 to 12 ft. deep, and this was filled with rubble masonry, 5 ft. thick, laid in Portland cement, to connect the plank facing with the canyon walls.

This dam contained 37,159 cu. yds. of rock, of which 6,000 cu. yds. were hand-laid in courses of dry rubble on the face, in a wall 15 ft. thick at the bottom and 5 ft. at the top. The remainder of the dam was in the form of loose, angular granite blocks, up to 4 tons in weight, dumped from cars and handled to some extent with derricks. No small quarry spalls or earth were used, and the result was a clean rock-fill which has only settled 3 ins. since final completion. A trestle was carried across the canyon, and the posts of this trestle were left buried in the embankment; a modern system of cable-way transport would have been cheaper, more rapid and better. As the hand-laid face wall was carried up, redwood timbers, 6 × 6 ins. and spaced 5 ft. 4 ins. apart on centers, were embedded to a depth of 4 ins. vertically in the masonry. To these timbers the planks were spiked, and as each row was put in place concrete was rammed into the 2-in. space between the plank and the wall, so as to give a full bearing to the plank. On the lower third of the dam the planks were 3 ins. thick; on the middle third, 2 ins., and on the upper third they were 1½ ins. thick and double throughout. Joints were broken, horizontally and vertically, as much as possible, and the jointe were calked and smeared with hot asphaltum.

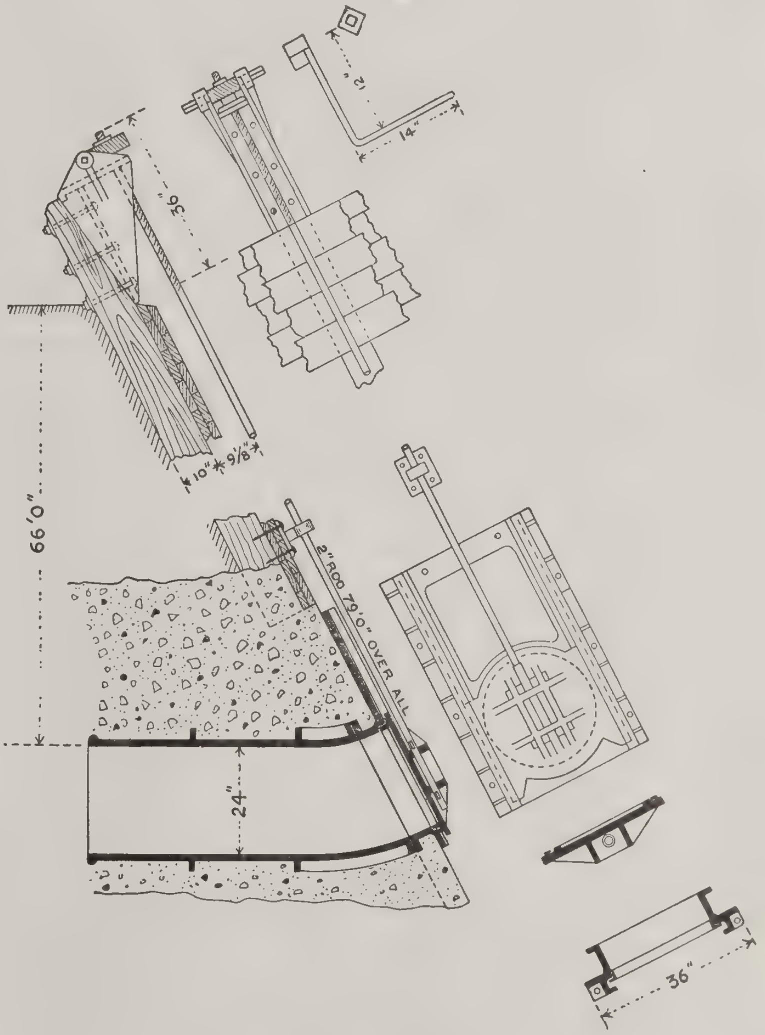
Springs were developed in the foundation excavation to the extent of 3 to 4 miner's inches constant flow. These were led by pipes to the outer toe; but when filled to the 57 ft. level, the maximum leakage was found to be 8 miner's inches, exclusive of the springs. This leakage remained quite constant, and it is doubtful whether it is due to percolation under the dam, through the disintegrated granite or to leakage through the joints in the plank facing. In any event, it is entirely harmless, though the loss of 100,000 gallons of water per day is an annoying one when it is needed for storage. The facing plank has been carried 3 ft. above the stone fill, as a wave protection, so that the ultimate crest is 9 ft. above the floor of the spillway. The outlet was originally designed to be controlled by a tower, and the foundation was laid at the upper toe of the dam on the south side; but the plan was changed; a grating was placed over the base of the tower a few feet above the gate covering the outlet; and the gate was set on an incline and controlled by a 2-in. rod leading up the incline to a worm-gear located above the crest of the dam. The outlet pipe is 24 ins. diameter, and is made of ordinary vitrified sewer pipe, laid in a trench and imbedded in concrete to a depth of 12 ins.

The total cost of this dam, under the contract, was $86,946.21, or $27.82 per acre-foot of reservoir capacity up to the floor of the spillway. The land for the reservoir site cost in addition $23,112, including clearing, and the total cost was $110,059, or $38.41 per acre-foot. The contract prices were unusually high for such work, and were as follows: Per cubic yard, earth excavation, 30 cts.; rock excavation, $1.10; rock-fill, $1.50; dry-stone masonry, $3.75; rubble masonry in cement, $8.00; concrete, $14.00; and lumber, $50 per M feet. It is the first rock-fill dam built in California for irrigation purposes; the older dams of this type having been used exclusively in mining operations.

Other dams of this general type, under construction or built, are the Lower Otay rock-fill-steel-core dam, described in our issue of March 10, 1898; the Morena dam on Cottonwood Creek, about 50 miles from San Diego; Upper Otay reservoir; Chatsworth Park, in San Fernando Valley, Cal.; and the Pecos Valley dam. The Morena dam is to be 160 ft. high and is expected to carry 150 ft. of water. It will contain 256,000 cu. yds. of stone. The outlet will be at the 30-ft. contour and consists of a tunnel, 6 × 6 ft. and 600 ft. long, cut in the solid rock, and in this tunnel will be two 24-in. and one 12-in. steel pipes, imbedded in concrete. These will connect inside with a steel intake inclined well or pipe, 36 ins. diameter, running up the side of the canyon at the toe of the slope of the dam, and fitted with 36-in. stops at every 30 ft. in height. These stops will be controlled by rods passing up the slope to the top. The dam is being built by a company under contract to deliver to the city of San Diego 12,960,000 gallons of water daily at a point four miles from the city. Mr. Schuyler says that the constructors seem to consider the services of an engineer superfluous, and there is practically no engineering



PLANS AND PROFILES OF ESCONDIDO DAM.



DETAILS OF GATE OF ESCONDIDO DAM.

supervision. The City Engineer of San Diego alleges that extraordinary negligence has been shown in laying the toe wall, which is said to have been built up 112.5 ft. high in 18 days!

At the Upper Otay reservoir the foundations were laid at the time of Mr. Schuyler's report, and while the canyon at the bottom is only 20 ft. wide, in porphyry rock, the dam may be built to a height of 100 or 120 ft. The Chatsworth Park dam succeeds two earthen dams previously carried away, and the new dam is quoted by Mr. Schuyler as an example of "how not to do it." This rock-fill dam is 41.3 ft. high above the creek bed, 100 ft. long on the bottom, and 159 ft. on top. It is 10 ft. wide on top, and slopes at an angle of 60°, or 1 on .057, on each side, giving a base of 60 ft. The water face is covered with Portland cement concrete, 8 to 16 ins. thick. The rock used for the fill is a soft sandstone, dumped in place without selection; and as everything loosened in the quarry was put into the fill, the proportion of earth and sand is very large. The angle of repose of the mass is thus flatter than that of rock alone, and flatter than the slopes proposed by the plans. The specifications were carelessly carried out, and the dam leaked considerably with 10 ft. of water behind it, and three-fourths of the lower face wall slid off two weeks after the contractor had "finished" his work. The work was done by contract for $9,000, partly payable in land. The company failed, and the dam is being reconstructed by building a dry hand-laid slope wall on the lower face, 4 ft. thick, and covering this with a masonry wall 6 ft. thick. The mortar used is half lime and half cement to three parts sand, and it will have an outer coat of 6 ins. of concrete. But all this is on the lower face of the dam.

The Pecos Valley rock-fill dams, near the town of Eddy, New Mexico, were built for storage reservoirs in 1889-90 and 1893. They differ from the others in using earth alone as a facing to stop leakage. The lower dam, built first, was 48 ft. high and 1,380 ft. long; the water slope of the rock-fill was 1 on 1½; width of rock base, 106 ft.; crown, 10 ft. wide. The earthen facing also had a crown width of 10 ft. and a slope of 1 on 3, covered with a pitching of loose stone for wave protection. This dam was ruptured in 1893 by a flood-wave in excess of the spillway capacity; a breach being made 300 ft. wide. It was immediately repaired and built 3 ft. higher, at a cost of $86,000, and the spillway capacity was increased to 33,000 second-feet, with the water 7 ft. below the top of the dam. The upper dam, built in 1893, was built in a similar manner, except that the rock-fill was made 14 ft. wide at top, and the earth fill only 6 ft. wide; the slopes remaining the same. The face of the rock-fill, against which the earth rests, was a hand-laid wall, 2 ft. thick, on a slope of 1 on ½. It required 102,400 cu. yds. of rock, 103,600 cu. yds. of earth, 3,800 cu. yds. dry retaining wall and 6,200 cu. yds. of rip-rap. It is said to have cost $170,000 complete. This dam is 52 ft. high, 1,686 ft. long, 20 ft. wide on top, and 280 ft. wide on the base. In 1895, when visited by Mr. Schuyler, it showed no signs of leakage or settlement, though the reservoir was more than half full.

BOOK REVIEWS.

UNSERE HOCHSCHULEN UND DIE AUFORDERUNGEN DES ZWANZCGSTEN JAHRHUNDERTS.—Von A. Riedler, Konigl, Geheimen Regierungerath und Professor. Berlin, 1898. A. Seydel. Paper; 10½ × 7½ ins.; pp. 120.

In this work on "German Universities and the Demands of the 20th Century," Prof. Riedler discusses the present state of German universities and technical colleges, and raises the question whether these institutions for highest education will be able to fulfill the national tasks of the future. He claims that engineering work is the pioneer of natural science and one of the principal features of modern culture. The author develops a scheme of reform of the German universities, recommending the uniting of the existing kinds of universities and completing the old universities by technical departments, embracing the whole of technical science. He hopes that this reform will result in a much more effective scientific and technical instruction, and besides will lead to a higher social appreciation of engineers and architects than now is the rule in Germany. In case the union proposed by him cannot be brought about, the author advocates a reform of the German technical colleges, aiming at thorough economical and general scientific education, but fights energetically against the attempt to join some one or other single branch of technical science to the old universities, because it would undoubtedly perish in such isolation.

FRANCHISES AND TAXATION IN CHICAGO.—Ninth Biennial Report of the Bureau of Labor Statistics of Illinois. Secretary, Geo. A. Schilling, Springfield, Ill. Chief Special Agent, Prof. E. W. Bemis (now of), Manhattan, Kan. Paper; 5½ × 8½ ins.; pp. 320; many tables. Address the Secretary.

This volume contains some very interesting studies of the street railway, gas and telephone companies of Chicago. By showing in detail the over-capitalization of the various companies, the prices charged by them for their services and the compensation, when any is rendered, paid the city for their franchises, the report paints a dark picture. If the figures presented are reliable, and they give evidence of having been prepared with care, although many of them are of necessity only estimates, then the people of Chicago are paying enormous tribute to the conpanies named.

The accounts of some of the financial transactions of these companies read like fairy tales, especially those relating to Mr. Chas. T. Yerkes, who is here shown as a modern rival of Midas.

The section on taxation shows the ridiculously low assessed valuation of Chicago property, a fact also brought out in the discussion of franchises. The chapters on gas and street railways were prepared by Prof. Bemis, whose monograph entitled "Municipal Ownership of Gas in the United States" is recognized as a creditable work. The report is to be welcomed as another addition to the scanty information available regarding the operations of street railway and other natural monopolies in our great cities.

ELASTICITAET U FESTIGKEIT.—By Prof. C. Bach, K. Wurtt. Baudirector; Professor of Mechanical Engineering at the Royal Technical High School, Stuttgart. Third edition, revised and greatly enlarged. Julius Springer, Berlin. 8vo.; pp. 570; numerous illustrations; 18 gelatine plates and many tables. $4.

This is the third and much enlarged edition of Professor Bach's admirable and practical book on the Elasticity and Resistance of the most important structural materials. The author deems it advisable to initiate his readers into the methods used in the practical solution of the problems treated of in the book in order that they may form their own opinions based on actual conditions. The student thus becomes impressed with the fact that he is not dealing with a field which has already been largely threshed out, as is commonly assumed, but is, on the contrary, only in an active state of development. He points out that numerous able mathematicians have advanced formulae more rapidly than their practical knowledge of concrete material seemed to justify, because they neglected the physical aspect, and, therefore, their solutions, otherwise correct, do not always solve practical problems.

In this edition, which is even more fully illustrated than the second, and in which no pains have been spared in typography, will be found many additions relating to the actual work of carrying out the author's investigations.

Among these may be mentioned the much discussed problems of compression of short specimens, flexure of columns and resistance of flat and flanged cast-iron and steel plates and heads. Professor Bach's work in this direction is unique, as he is the first to solve these problems correctly and demonstrate his conclusions by actual tests. It is to be regretted that this valuable work has not yet been translated into English. We can heartily recommend it to any American engineers who read German.

WEALTH AND PROGRESS OF NEW SOUTH WALES, 1896-97.—By T. A. Coghlan, Government Statistician. Tenth issue. Sydney: Government Printer. Boards: 8¾ × 5½ ins.; pp. 1,028.

Mr. Coghlan here gives an interesting historical sketch of Australia, commencing in 1503, but carried out in considerable detail from the actual founding of the English colony at Botany Bay in 1788. The succeeding parts are similar in outline to previous issues, dealing with the area, physical configuration, climate, geology, fauna and flora, of New South Wales. Following this we have the detail of the government, commerce, industries, population, vital statistics, instruction, etc. Under the head of railways we find the history of their development from 1846, to the operation of 2,639 miles of road in 1897. Of this total 2,476 miles are single track, and the average cost per mile is put down at $60,660, in a total expenditure for railways of $160,122,690. For the year ending June 30, 1897, the gross revenue from the government railways of New South Wales was $15,073,710, an increase of $971,625 over the preceding year. The working expenses were $8,006,090, and the net earnings were thus 46.8% of the total earnings. It is interesting to note that while the home government maintains a fleet of ten warships on the Australian station, all the colonies entered into an agreement for ten years with the British government, in 1887, to pay a subsidy towards the maintenance of an Australian auxiliary squadron. This annual subvention amounts, for the whole of Australasia, to $455,000 for maintenance and $175,000 for interest on cost of construction at a 5% rate. The resultant fleet entered Port Jackson in 1891, and consisted of five fast cruisers, of 2,575 tons displacement each, and two torpedo gunboats, of 735 tons; of these, three cruisers and one gunboat are always kept in commission, while the others are held in reserve in Australian ports. But the Australian government has no voice in the management of these vessels or any control over their movements; but this force is always exclusive of the regular fleet maintained in Australian waters, and the British government replaces any vessel lost.

THE RELATIONS BETWEEN CITIES AND TOWNS AND STREET RAILWAY COMPANIES IN MASSACHUSETTS. Report of Special Committee consisting of Chas. F. Adams, of Lincoln; Wm. W. Crapo, of New Bedford, and Elihu B. Hayes, of Lynn; Walter S. Allen, New Bedford, Secretary. Paper; 6 × 9 ins.; pp. 296. Address one of those named above.

In our issue of April 7, 1898, we noticed the advance pages of the body of this report and commented editorially on the bill submitted by the committee to the legislature for establishing the future relations between street railway companies and municipalities. The full report, now before us, contains nearly 250 pages of appendices giving a large amount of valuable information on the subject under discussion. In the first appendix the secretary reviews in detail the history and present status of street railways in Massachusetts. Next there are given brief "Abstracts of the Statutes of the Various States in Relation to Franchises and Methods of Taxation of Street Railways." Then follows a general description of the street railway systems and franchises of 14 American and 22 European cities, this information apparently having been largely obtained by the commission at first hand. An abstract of a paper entitled a "Statement in Relation to Municipal Ownership and Operation of Street Railways in England," by Robt. P. Porter, forms still another appendix, besides which there are others quoting from previous Massachusetts reports bearing on the subject and showing how the law proposed by the commission would affect the revenue from street railways now received by the municipalities and what the various railway companies would have to pay as commutation for relief from the burdens of paving and snow removal now imposed upon them.

The paper by Mr. Porter is designed to show how the advocates of municipal ownership have misinterpreted English experience in this line. One of his chief arguments is that American capitalists would have done better in these English cities and towns than the municipalities themselves have done. There are certainly good reasons for making the comparison, instead, between public and private ownership in England, and then applying the conclusions to the probable results from public and private ownership in America. We have been very forward in our street railway development under private ownership, but England seems to have been backward in this matter under both private and public ownership. Mr. Porter has omitted at least one factor entering into the present condition of street railway development in England, whether under public or private ownership. He compares the street railway mileage and population of a number of American and English cities, but states the areas of neither; certainly area is an important factor in the case. Nor does he bring out the fact that whereas the capitalization of both public and private street railways in England are closely in accord with their actual cost, many of our American street railway companies are capitalized for many times their legitimate cost, so that under municipal ownership here much lower fares might prevail than are charged by the companies. English conservatism, in some instances, has saved and will continue to save vast sums which American capitalists have recklessly spent in more or less foolish experiments both in adopting new railway methods and making unwarranted extensions. The American plan is to charge all these expenditures to the capital account, instead of to profit and loss, and attempt to earn dividends on them. In other words, the public is called upon to bear the penalty of all the blunders or miscalculations of managers of private railways and often, but not always, has to do so. English managers of private railway companies do not have so much freedom in this respect, which partly explains their conservatism. In Massachusetts, also, the street railway companies are under the wholesome supervision of the State Railway Commissioners, but in most or all of our other American commonwealths these corporations manipulate their capital accounts about as they please.

It is not enough to show, as Mr. Porter attempts to do, that the mileage charges of American street railways are as low or lower than those on the municipal systems of England. The real question at issue is, how do prices in England compare under private and municipal ownership, and how would they compare here?

We do not doubt but that Mr. Porter is entirely right in some of his criticisms of American claims for municipal ownership abroad, and we are glad to say that he appears to have taken great pains to ascertain the facts bearing on the subject. But in interpreting these facts and applying them to American conditions we think he shows himself quite as much a partisan of private ownership as those he is criticising have been partisans of municipal ownership.

THE PROPOSED STORAGE DAM AND RESERVOIR for the water-works system of Columbus, O., has been reported on by Mr. Jas. D. Schuyler, M. Am. Soc. C. E., of Los Angeles, Cal., who spent some time in Columbus for that purpose. Mr. Schuyler approves the general plan proposed by Mr. Julian Griggs, Chief Engineer of Public Improvements of Columbus, but recommends that the concrete dam be 52 instead of 30 ft. high, and that instead of an overflow dam a spillway be provided. A dam 52 ft. high would impound 5,681,000,000 gallons of water and flood nearly 500 acres, forming a long, narrow reservoir, very favorable to sedimentation. Mr. Schuyler also recommends that the curvature of the dam be increased by diminishing the radius from 1,910 to 800 ft., or less.

◆

THE LITIGATION OVER UNDERGROUND WATER supply, brought by Walter R. Smith against the former city of Brooklyn, N. Y., has again been decided in favor of the plaintiff. The plaintiff alleged that an artificial pond, from which he obtained ice, had been dried up by the driven wells sunk by the city a few years ago. The facts in the case, together with its course in the courts were given in an editorial on "Riparian Rights in Underground Waters," in our issue of Aug. 19, 1897. The present decision was made by the Appellate Division of the Supreme Court of the State of New York, and affirms an award of $1,800 damages to Mr. Smith, made in a jury trial.

◆

THE SECOND TRIAL OF THE SUIT of Joseph H. Smith et al vs. Salt Lake City, Utah, has been completed, and the decision of the referee was rendered July 14. This was a suit brought by the bondsmen of Dubois & Williams, the original contractors for the Parley's canyon conduit for supplying Salt Lake City with water. (See Engineering News, Oct. 22, 1896.) The bondsmen completed the work at a loss, and soon thereafter filed an action against the city to recover $97,000. They alleged in their complaint that the city changed the route of the conduit after the original contract was entered into, thus requiring the use of much more material than would otherwise have been needed. The trial was had before the same referee as in June, 1893, and the city won on every point. As that was in territorial days, the case came up before Judge Hallett of the Federal Court at Denver, who last winter granted a new trial, being of the opinion that it was to be assumed that a route had been established before the contractors bid upon the work, and if so that the contractors were entitled to extra pay. The case has been very strongly contested by the city, and at the second trial a number of the leading engineers and contractors of the state were employed, who inspected the completed work very thoroughly and who showed that the contractors did not lose the large amount of money claimed, and that one route would have been as expensive as the other. However, by the late decision, the referee awarded the plaintiffs $10,044, together with interest at 8%, from Feb. 4, 1892 (the date of the completion of the work), making a total of $15,245, and also the costs of the several hearings, about $3,000 more. The referee's report will have to again go to Judge Hallett, and it is likely that a bitter contest over its confirmation will be made, as neither side is satisfied with it.

THE EFFECTIVENESS OF AUTOMATIC SPRINKLERS was well shown in a recent fire in a storehouse at the Atlantic White Lead Works in Brooklyn. Only a portion of the building was protected by sprinklers. The fire originated on the second floor, about 30 ft. from the protected portion, and extended through all of the unprotected part of both the second and third floors, but was completely checked at the point where the sprinklers were located, the stock, plumber's materials packed in hay, being wet thoroughly. The loss would have been insignificant if the whole building had been protected.

◆

THE MOST SERIOUS RAILWAY ACCIDENT of the week occurred Aug. 1 on the Central of Georgia Ry., at Fort McPherson, Ga., in which a train carrying troops for the Camp at Lithia Springs was run into by a freight train. No soldiers were hurt, but two railway employees were killed and three injured.

◆

EXCESSIVE EXPANSION OF THE BROOKLYN Bridge by the extreme heat of July 29, coupled with a blockade of trolley cars covering practically the entire suspended span, resulted in a slight buckling of the bottom chords of four of the six stiffening trusses. The damage done was unimportant in itself, and is chiefly interesting for the lessons which it teaches respecting certain features of the construction and the need of a more rigid regulation of the electric railway traffic. In our next issue we hope to give fuller details of the accident.

◆

THE REPORT ON THE "BOURGOGNE" DISASTER, made by the Court of Inquiry held at Halifax, N. S., exonerates the Captain and crew of the sailing vessel "Cromartyshire" from all blame for the collision. Concerning the course on which the French steamer was sailing at the time of the collision, Capt. W. H. Smith, of the Royal Naval Reserve, who was the Government's special commissioner in the investigation, said:

> It appears to me that "La Bourgogne," as a mail steamship starting from New York, was not in the position at the time of the collision as indicated by the steam lanes upon the pilot chart of the North Atlantic, where the steamship routes are laid down, and in the note upon the chart it is stated: "The principal transatlantic steamship companies have adopted these routes, and sailing vessels are requested to avoid them as much as possible."
>
> It also appears to me that it is highly desirable that the rule of following the steam lanes should be made binding on all steamships navigating the Atlantic, when plying between New York and European ports.
>
> "It is of much importance to all concerned that steamers carrying a large number of passengers between New York and European ports should, if practicable, traverse the Atlantic upon such safe courses that in all probability would take them clear of the most dangerous locality, and, if possible, steamers should especially avoid that portion where fogs are frequently known to exist and may be encountered at any time, more particularly during the summer months under certain conditions of weather and direction of wind.
>
> "I am of the opinion that it is desirable that new lane routes should be selected for fast passenger steamers to and from American ports. These routes should be established by law and adopted by the governments of the various localities.
>
> "The route I propose is as follows: Leaving New York, a course direct from Sandy Hook to longitude 70° west, in latitude 40° north, and follow that parallel of latitude until longitude 47° west is reached, then each ship could pursue the great circle course, either to Fastnet Rock Lighthouse, coast of Ireland, or the Scilly Islands, as the case might be. On the westerly or outward passage, steamers should go 30 miles to the northward of this route. Upon such a route, probably, no fog or icebergs would be encountered, and only an occasional derelict, which could be seen by a good lookout."

◆

FIREPROOF WOOD IN THE NEW WARSHIPS is advocated by Chief Naval Constructor Hichborn; but is opposed by the other three members of the Naval Construction Board, and the matter is referred to Secretary Long for final decision. The burning of the Spanish ships at Santiago has called renewed attention to the danger resulting from combustibles on board war vessels. On the other hand the fireproofing chemicals used in treating the wood are said to cause corrosion wherever it comes in contact with iron, and if the wood is exposed to moisture the chemicals may become leached out and the wood may lose its fireproof character. A later report states that the Secretary has approved Constructor Hichborn's report, and that all wood used in the new vessels will be fireproofed.

◆

A BURGLAR-PROOF VAULT OF ARMOR PLATE is being constructed by the Carnegie Steel Co. for the Union Trust Co., of Pittsburg. The interior of the safe, or vault, is to be 18½ × 16½ ft. by 9½ ft. high. Eleven plates of face-hardened, reforged nickel steel armor plate are to be used, aggregating 396,750 lbs. The size and location of these plates are described as follows: The front plate will measure 234 × 114 × 8 ins., and will weight 46,150 lbs. It will be reinforced by a rolled steel plate 222 × 102 × 6½ ins., weighing 38,200 lbs. The door will be circular, 87 ins. diameter, 8½ ins. thick, and will weigh 15,400 lbs. It will also be reinforced, but with a cast-steel plate, 86 ins. diameter, 3 ins. thick in the center and 6 ins. thick on the edges, weighing 7,500 lbs. The back plate will be 234 × 114 × 6 ins., 45,000 lbs., two side plates, 208 × 110 × 6 ins., 39,000 lbs. each; two top plates, 226½ × 106 × 6 ins., 41,000 lbs. each; two bottom plates, 234 × 106 × 6 ins., 42,250 lbs. each. The vault is to be constructed under the Hollar-Kennedy patent. No bolts are to be used, the plates being dovetailed together. The flanges of the plates are wedged snugly in undercut grooves of corresponding shape cut in the connecting plates, thus preventing movement in any direction. The vault will have a foundation of heavy masonry. The door will be ground to an air and gas-tight joint and will be secured by 27 heavy radial bolts. The mechanism for actuating the bolts will be checked by three time locks.

◆

A STAND OF COLORS, costing approximately $500, will be presented by The Engineers' Club of New York city to the first of the three regiments of Volunteer Engineers, authorized by Congress and now in camp at Peekskill, N. Y. It is also proposed to purchase a searchlight outfit for the first regiment, and The Engineers' Club has undertaken the work of raising the amount necessary, about $3,000. Subscriptions should be sent to Mr. S. W. Baldwin, Treasurer, care of The Engineers' Club, 374 Fifth Ave., New York city.

◆

EXPORTS OF MANUFACTURED GOODS from the United States for the fiscal year ending June 30 were the largest ever recorded, amounting to $288,871,449, or nearly 12 million dollars more than in any preceding year, more than double the exports of such goods a decade ago, and almost three times as much as in 1880. It is interesting to note that exports of bicycles amounted to $6,846,529, against less than two million dollars in the preceding year. The Bureau of Statistics of the Treasury Department has issued an interesting summary, showing the exports of the principal lines of manufactured goods in the last fiscal year and in the year ending June 30, 1888. We reprint it as follows, and would call especial attention to the growth in the exports of manufactures of iron, steel and copper.

	Year ending June 30.	
	1898.	1888.
Articles exported.	Value.	Value.
Starch	$1,850,353	$202,932
Flax, hemp and jute manufactures	2,557,465	1,391,216
Instruments for scientific purposes	2,770,803	714,514
Cars, carriages, etc.	3,424,419	2,243,756
Fertilizers	4,359,834	1,255,028
Tobacco, manufactures of	4,818,493	3,578,457
Paper, and manufactures of	5,494,564	1,078,561
Paraffine and paraffine wax	6,030,292	2,163,242
Cycles, and parts of	6,846,529	......
Agricultural implements	7,609,732	2,645,187
Chemicals, drugs, dyes & medicines	9,441,763	5,633,972
Cotton, manufactures of	17,024,092	13,013,189
Leather, and manufactures of	21,113,640	9,583,411
Copper, and manufactures of	32,180,872	3,812,798
Mineral oil, refined	51,782,316	47,042,109
Iron and steel, manufactures of	70,367,527	17,763,034

In view of the interest just now felt in our trade with the Orient, it may be remarked that Japan bought 53 million gallons of our mineral oils and China 44 million gallons.

◆

AMERICAN INTEREST IN THE PARIS EXHIBITION of 1900, it is hoped, will now be stimulated by the appointment of Mr. Ferdinand W. Peck as Commissioner-General for the United States. Mr. Peck was chairman of the Finance Committee of the Chicago exhibition, and was a member of the preliminary commission which was sent to Paris over a year ago. The business manager on Mr. Peck's staff will be Mr. Paul Blackman, who was Chief of Concessions of the Chicago exhibition. A permanent office of the Commission will shortly be opened in New York city, and several departments will be created, including those of agriculture, transportation, electricity, fine arts, machinery, American inventions, and mines and mining. The head of the last named department will be Mr. J. F. V. Skiff, who was the chief of the similar department in the Chicago exhibition.

◆

THE PNEUMATIC MAIL TUBE SYSTEM connecting the Brooklyn and New York General Post Offices was opened Aug. 1 before about 200 persons. The first carrier made the round trip from Brooklyn and back in six minutes and two seconds. The cost of the plant was about $60,000, and the government is to pay a rental of $14,000 per year to the New York Newspaper and Transportation Co. for carrying first-class matter.

◆

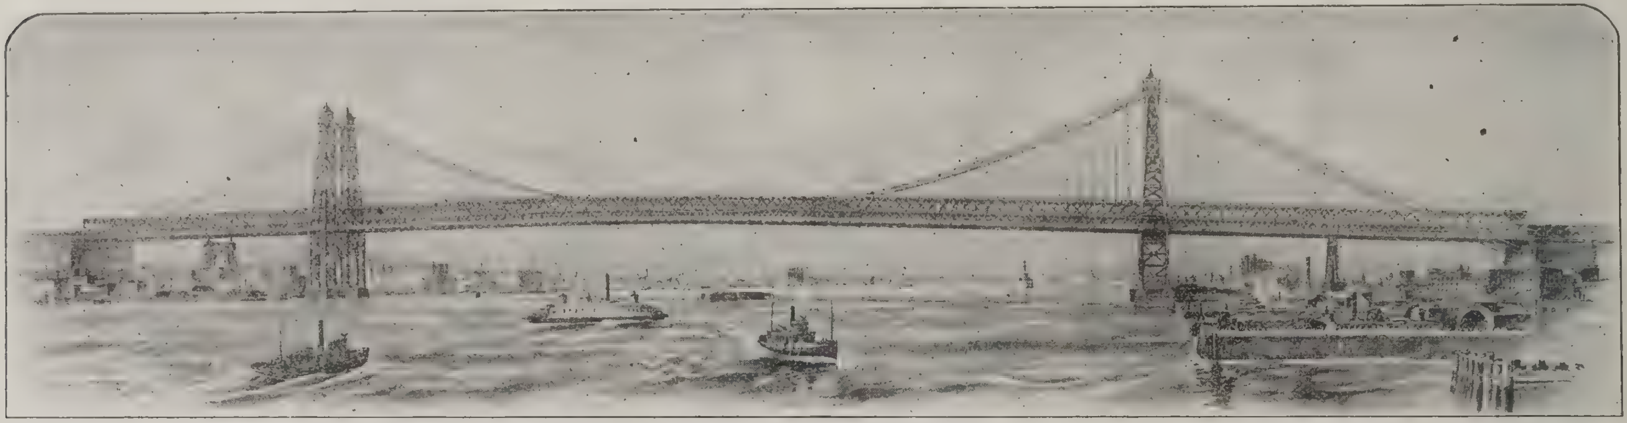
LIGNITE is being used for fuel by the Houston & Texas Central Ry. For switching engines it is used alone, with improved draft appliances and the diamond stack, but for road engines it is mixed with equal parts of coal. The results of the use of lignite are given by Mr. S. R. Tuggle, Superintendent of motive power of the road, in a paper read before the Texas Railway Club. He says that besides the saving in cost, due to the shorter haul, large beds of the lignite being near the main line of the road, there has been a saving in repairs of flues, stay-bolts and fire-boxes.

THE NEW EAST RIVER BRIDGE, NEW YORK CITY.

We show herewith a perspective view of the New East River Bridge, now under construction between New York and Brooklyn, which we have had engraved from a water-color drawing made for the New East River Bridge Commission by Mr. C. W. Reinhardt, Chief Draftsman of Engineering News. Details of the tower foundations, anchorages, end spans and towers proper of this bridge were published in our issues of May 27 and Sept. 9, 1897, and Feb. 17, 1898, and only a few of the leading dimensions of the completed structure will be given here. These are as follows:

	Feet.
Length between terminals	7,200
Width. out to out	118
Minimum height at pier-head lines	117
Minimum height at center of span	135
Height of masonry in tower foundations above mean high water	20
Height of center of cables at top of towers above mean high water	335
Width of carriageways, each	18
Width of two footwalks, each	12
Width of four trolley-car tracks, c. to c.	10
Width of two elevated railway tracks, c. to c.	12
Distance apart of stiffening trusses, c. to c.	72

The towers above the masonry and the entire suspended structure, except the flooring, will be of steel. The four suspension cables will each be 17½ ins. in diameter.



PERSPECTIVE VIEW OF THE NEW EAST RIVER BRIDGE BETWEEN NEW YORK AND BROOKLYN.
L. L. Buck, M. Am. Soc. C. E., Chief Engineer.

As most of our readers will remember, Mr. L. L. Buck, M. Am. Soc. C. E., is Engineer in Chief of the new bridge, and Mr. O. F. Nichols, M. Am. Soc. C. E., is his principal assistant. Work is now in progress upon the tower foundations and the anchorages, and bids have been received for constructing the towers and end spans, but contracts have not been awarded.

* * *

THE MACHINERY OF THE NEW TORPEDO BOATS AND TORPEDO-BOAT DESTROYERS.

The machinery of the 12 new torpedo boats and 16 torpedo-boat destroyers is described as follows in the official circular to bidders, issued by the Navy Department. The bids for these vessels are to be opened on Aug. 23:

Torpedo Boat.

The propelling engines will be of the vertical four-cylinder, direct-acting, triple-expansion type, each with cylinders 14, 22 and 25¼ ins. diameter and 18 ins. stroke. The indicated horse-power of the propelling engines will be about 3,000 when the engines are making about 350 revs. per min. The propelling engines will be placed in separate water-tight compartments, with the high pressure cylinders forward and the low pressure cylinders aft.

The main engines will be balanced in an approved manner. The main valves will be piston valves, one for each h-p. cylinder, operated by the Stephenson link motion. Each main piston will have one piston rod, with a crosshead working in a slipper guide.

The framing of the engines will consist of vertical forged-steel columns, stayed by forged and cast-steel ties and braces. The engine bedplates will be of cast steel, supported on forged steel keelson plates built in the vessel.

The crank shafts will be made in one section and will be hollow. The shafts, piston rods, connecting rods, valve rods, eccentric rods, and working parts generally, will be forged of nickel steel.

There will be two condensers made entirely of composition and sheet brass. Each will have a cooling surface of about 1,240 sq. ft., measured on the outside of the tubes, the water passing through the tubes. For each main engine there will be one double-acting air pump, driven from the main engine shaft. The circulating pumps will be of the centrifugal type, one for each condenser.

The propellers will be right and left, of manganese bronze or approved equivalent metal.

There will be three water-tube boilers constructed for a working pressure of 250 lbs. per sq. in. Two of these boilers will be placed in a water-tight compartment forward of the engines and the other one will be placed in a water-tight compartment abaft the engines. The total grate surface will be at least 137 sq. ft. and the total heating surface at least 7,544 sq. ft. There will be three smoke pipes, one for each boiler.

There will be two main feed pumps, one in the forward fire room and the other in the after engine room. These pumps will each have a capacity of 147 gallons per minute at a piston speed of 100 ft. per minute. There will be one auxiliary feed pump, located in the forward engine room. The capacity of this pump will be 147 gallons per minute at a speed of 100 ft. per minute. There will be one fire and bilge pump in the after engine room, having a capacity of 147 gallons per minute at a speed of 100 ft. per minute.

There will be two blowers in the forward and one in the after fire room. There will two evaporators and one distiller, and such other auxiliary or supplementary machinery, tools, instruments, or apparatus as are described in the detailed specifications or shown in the drawings.

The weight of all the machinery and boilers, including auxiliaries and radiators and water in the boilers, condensers and pipes, and such stores and spare parts as may be carried on board when fully equipped must not exceed 79.745 tons.

Torpedo-Boat Destroyers.

The propelling engines will be alike, and each will be placed in a separate water-tight compartment. These engines will be of the vertical four-cylinder, direct-acting, triple-expansion type, each with cylinders 20½, 32 and 38 ins. diameter and 22 ins. stroke. The indicated horse-power of propelling engines will be about 8,000 when the engines are making 327 revs. per min., the steam pressure at the engines being 250 lbs. per sq. in. above atmosphere. The order of cylinders will be as follows, beginning forward: For the starboard engine, second low-pressure, intermediate, high and first low-pressure; for the port engine, first low-pressure, high, intermediate, second low-pressure. The cranks will be at 90°, the high and first low-pressure cranks being opposite, as also the intermediate and second low-pressure, the second pair being at right angles with the first pair. The weights of the pistons will be such as to make the weights of reciprocating parts the same for all cylinders, the weights of the air-pump pistons and moving parts actuating them being taken into consideration. Any other system of balancing, which the contractors may wish to use, will be considered by the Bureau of Steam Engineering. The balancing of rotating weights of main engines by counterweights on the crank webs is left optional with contractors.

The main valves will be worked by means of Stephenson double-bar links. All the main valves will be piston valves, double-ported for steam, there being one for each high-pressure, two for each intermediate-pressure, and two for each low-pressure cylinder.

Each main piston will have one piston rod, with a crosshead working in a slipper guide. The framing of the engines will consist of vertical forged-steel columns, well stayed by diagonal braces. The engine bedplates will consist of a separate steel casting for each bearing, all supported upon and bolted to two fore-and-aft plates, which latter are supported by and form part of the engine keelsons, carefully and strongly worked into the framing of the vessel. The crank shafts will be made in two sections and will be hollow.

The shafts, piston rods, connecting rods and working parts generally, will be forged of high-grade steel.

There will be two condensers, made entirely of composition and sheet brass. Each will have a cooling surface of about 3,470 sq. ft., measured on the outside of the tubes, the water passing through the tubes. For each propelling engine there will be two double-acting vertical air pumps driven from the high and intermediate pressure crossheads. The circulating pumps will be of the centrifugal type, one for each condenser. The propellers will be right and left, of manganese bronze or approved equivalent metal.

There will be four water tube boilers, constructed for a working pressure of 300 lbs. per sq. in. Two of these boilers will be placed in a water-tight compartment forward of the engines, and the others will be placed in a water-tight compartment aft of the engines. The boilers in the after boiler compartment and the after boiler in the forward compartment will be alike, each containing about 80.5 sq. ft. of grate surface; the forward boiler will not be as wide as the others, and will contain about 73.5 sq. ft. of grate surface, the length of grates not exceeding 7 ft. in all the boilers. The total grate surface will be at least 315 sq. ft. and the total heating surface at least 17,768 sq. ft. There will be four smoke pipes, one for each boiler.

There will be four main feed pumps, each of a rated capacity of about 150 gallons per minute. They will be located, one in each engine room, and one in each fire room. All these pumps will draw from the feed tanks and from the reserve water tanks, as specified elsewhere, and will deliver into the main feed pipe. The main feed pumps located in engine rooms will deliver into both the main and the auxiliary feed systems. The main feed pump in the after engine room will draw from the reserve water tanks through a separate pipe. Both main feed pumps in engine rooms will draw from the air-pump channel ways.

There will be two auxiliary feed pumps, one in each fire room, of the same capacity as the main feed pumps. They will draw from the feed tanks, the reserve water tanks, and the sea, and discharge into the auxiliary feed pipe, into the fire main, and the ash ejectors. There will be in each engine room a fire and bilge pump. These pumps will draw from the bilge, through the auxiliary drain, and from the sea, and deliver overboard and in the fire main. There will be two blowers in each fire room.

The water level in each boiler will be controlled by an approved feed regulator.

There will be two evaporators and one distiller, and other auxiliary or supplementary machinery, tools, instruments, or apparatus as described in the detailed specifications.

The weight of all the machinery and boilers, including auxiliaries and heaters and water in the boilers, condensers, pipes, and feed tanks, and such stores and spare parts as may be carried on board when fully equipped will not exceed 190 tons.

THE "BOOTJACK" SIGNALS OF THE LAKE SHORE AND MICHIGAN SOUTHERN RY.

In the early use of railway signals and signaling little or no attempt was made at uniformity, and each road used such forms of targets, arms, etc., as it deemed best. As the art of signaling has improved and its use has become more general, however, the advantages incident to uniformity in signals and rules have become more generally recognized, and at the present day the semaphore form of signal is almost universally considered as the standard form, although the use of disks is still continued in certain automatic signals. Even in England a few examples of obsolete forms of signals are still to be seen; and in this country, where the introduction of signaling on a large scale is of comparatively recent date, there are still in use a number of special and peculiar signals which have been introduced by individual roads and are still continued in service.

An example of these is the "bootjack" signal, which is a feature of the Lake Shore & Michigan Southern Ry., and the general form of which is shown in Fig. 1. The signal has two arms at right angles to one another, both arms being in one piece, which is pivoted at the heel, a small counterweight at the heel balancing the arms and facilitating the working of the signal, besides returning it always to the "danger" position should the operating mechanism be broken. On the spindle of the signal is keyed a cogwheel, whose teeth engage with a rack on a vertical rod, to the lower end of which is attached a lamp. This lamp slides up and down in a box fitted with four or six lenses on one or both sides, according as the signal has four or six positions, and governs train movement in one or both directions. For six-position signals, two lamps are usually employed, placed side by side and moved together, showing two lights for each position of the arm. The signal is the invention of Mr. Wm. Gravit, Master Carpenter of the Lake Shore & Michigan Southern Ry., and has been in use since about 1881. It is used entirely on the main line, and to some extent on the branches, for block or train-order signaling, and is also used at junctions and for governing switch movements.

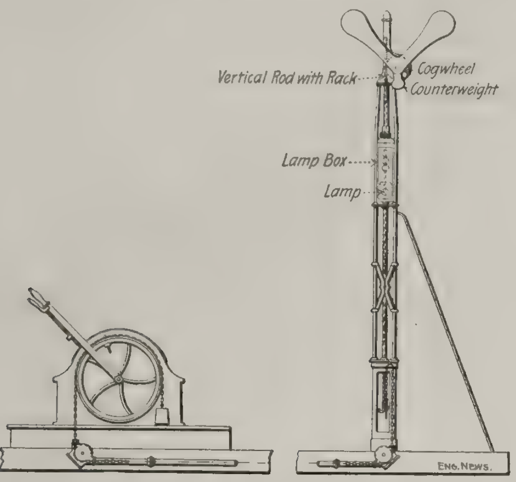

Fig. 1.—Bootjack Signal on the Lake Shore & Michigan Southern Ry. (Danger Position.)

In governing the movement of trains the signal has four positions: (1) Both arms pointing upward in V shape, both tracks blocked; (2) one arm horizontal and pointing south (and the other hanging down), south track blocked; (3) one arm horizontal and pointing north (and the other hanging down), north track blocked; (4) both arms pointing downward like an inverted V, both tracks clear. For these indications only two colors are used, white and red. At crossings and junctions, however, two additional positions are used, with the arm forming a horizontal V on one or other side of the post. For these signals there are six lenses, one above the other, but in most of the six-position signals there are two lamps placed side by side and moving together, showing two lights of the same or different colors for each position of the arm. For these signals white, red, and green lenses are used. The arms are invariably painted red on both sides.

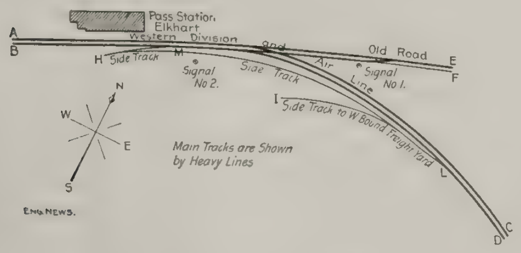

Fig. 2.—Plan of Junction at Elkhart, Ind.; L. S. & M. S. Ry. (Showing Signals).

The arrangement and indications of the signal will be clearly understood from Figs. 2 to 5. In Fig. 2 is shown a plan of the junction of the single track Old Road, with the double track Air Line and Western Division at Elkhart, Ind. The junction of these three divisions is opposite the station building, and train movements are governed by two "bootjack" signals and a single-arm block signal at the west end of the yard, 2,300 ft. west of the station. The sidetrack, I, leads from the Air Line into the westbound freight yard. The sidetrack, H, connects with both the Air Line and the Old Road. Eastbound freight is passed from H to to the Air Line either at M or around the sidetrack to L. Signal No. 1 is for switching movements only, and is a six-position double-lamp signal. Signal No. 2 refers to eastbound trains only, and its two lamps show in one direction only. The positions and lights of these two signals for their several indications are shown in Fig. 3. Westbound trains are controlled by the single-arm signal above mentioned, passenger trains from the station to this signal being given clearance cards through the yard.

Fig. 4 is a plan of the junction of the Jackson Branch and Monroe Branch with the main line of the Old Road at Lenawee Junction, Mich. Two signals are used, one of which is a "bootjack" with a single lamp showing a light in each direction, and the other is a pivoted red arm or target with two red lamps suspended from it. The positions and indications of these two signals are shown in Fig. 5.

These signals appear to be somewhat complicated and confusing in their indications, although we are informed that no complaints in these respects have been made by the operating department. Nevertheless the use of odd and peculiar signals is not to be recommended in these days, the advantages of uniformity having been so well established, nor is it good practice to attempt to make one signal give so many indications. When some more modern system of block signaling is introduced on the Lake Shore & Michigan Southern Ry. it is to be hoped that it will conform to the accepted standards, for reasons which have been editorially discussed in our issues of Jan. 20 and May 12.

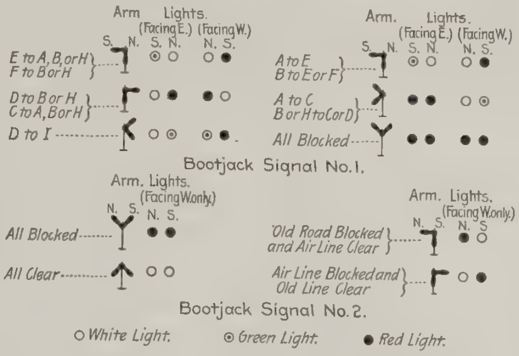

Fig. 3.—Positions and Colors of Four-Position and Six-Position Bootjack Signals at Elkhart.

It may be noted that on this road there is no signal engineer in charge of either the interlocking plants or the block or train-order signals, the latter being under the telegraph and operating departments. This anomalous condition of affairs is not by any means confined to the L. S. & M. S. Ry., however, as shown in a paper by Mr. W. H. Elliott, in our issue of Jan. 20; but in view of the rapid growth of signaling and block working on important lines it is most desirable that all work of this kind should be concentrated under the charge and supervision of one head in one department.

THE FAIRMOUNT PARK ARCH BRIDGE, PHILADELPHIA.

(With two-page plate.)

In our issue of July 2, 1896, we published the accepted design made by the Phoenix Bridge Co., for the new bridge to be built by the Fairmount Park Transportation Co., over the Schuylkill River, Fairmount Park, Philadelpia. This structure is now completed and in service, and on our double-page plate this week we present some of the more important metal work details and other interesting structural features of the work. It may be recalled to mind in this connection, also, that shortly after the design for this bridge was accepted there arose some discussion as to its fitness, which was given quite fully in Engineering News of Aug. 13, 1896. A study of the details shown here is made of somewhat more interest by reading this discussion in the same connection.

The general design of the Fairmount Park bridge is shown by Fig. 1. It consists of four 208 ft. stiff braced arches flanked on one end by two 70-ft. and one 85-ft. lattice spans, and at the other end by two 70-ft. and one 40-ft. spans. The total length of the bridge, excluding the embankment approaches, is thus 1,097 ft. Two electric railway tracks, a carriage-way and a foot-walk cross the bridge, the total width of 79 ft. 3 ins. being divided between them, as shown by the transverse section of the floor, Fig. 2. A special feature of the design which may be noted here is the method adopted for taking care of the grade to make it the least noticeable. This method consisted in making each arch of increasing depth as called for by the grade, but keeping the distance between the upper and lower chords at the center of the arch in each case the same. Had the arches been kept alike and the distances between the chords made to correspond to the grade, it was considered by the designers that the effect would not have been so good; as the change in grade between two arches would have been emphasized by this changing distance between the chords.

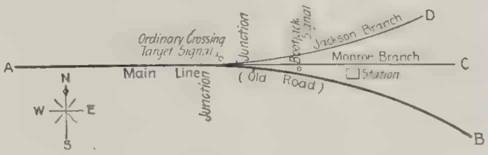

Fig. 4.—Plan of Lenawee Junction, Mich., L. S. & M. S. Ry. (Showing Signals).

The metalwork was proportioned for the following requirements:

(1) The floor beams and stringers are to carry a loading of 100 lbs. per sq. ft. over all parts of the sidewalk and driveway or a 20-ton load on a wheelbase of 9 ft. on any part of the driveway; and for 1,000 lbs. per lin. ft. of the railway tracks, or an electric car weighing 25 tons loaded followed by another car weighing 20 tons loaded, on a total wheelbase of 78 ft.

(2) The trusses are to carry the full area of the sidewalk and driveway over the whole span loaded with 80 lbs. per sq. ft., and 1,000 lbs. per lin. ft. over each railway track. The dead load was assumed to be 7,800 lbs. per lin. ft.

The strains induced by this loading are shown for one of the main arch ribs by Fig. 3, which also shows the panel arrangement, web system and end bearing construction in a general way.

Taking up one of the main arches more in detail, it will be seen that it is composed of three parallel ribs spaced 28 ft. apart c. to c. A stiff lateral system braces the ribs together in the plane of the bottom chord. The top chords are braced laterally only by the floor system, which, as will be seen later on, is an unusually stiff one. The web and chord connections are all riveted rigidly; with pins at center and ends. Fig. 4 shows the principal details of the center connection and one adjacent panel, and Fig. 5 similar details of one end bearing and the three adjacent panels. These drawings explain themselves.

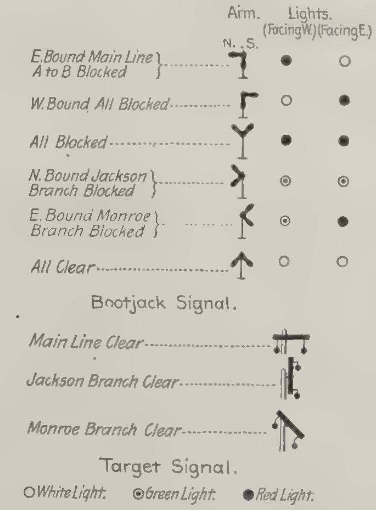

Fig. 5.—Positions and Colors of Bootjack and Target Signals at Lenawee Junction.

It will be noticed from Fig. 3 that the ends of the arch ribs are carried by steel shoes and bearing plates. The bearing plates of 1½-in. wrought steel were anchored to the masonry first and the location of the steel shoe castings fixed on the plates after all the piers were finished. The holes for the anchor bolts connecting the shoe castings to the bearing plates were drilled by template after the exact location of the respective shoes had been determined. This construction proved to be very efficient, not the slightest movement being noticed in swinging off the arches.

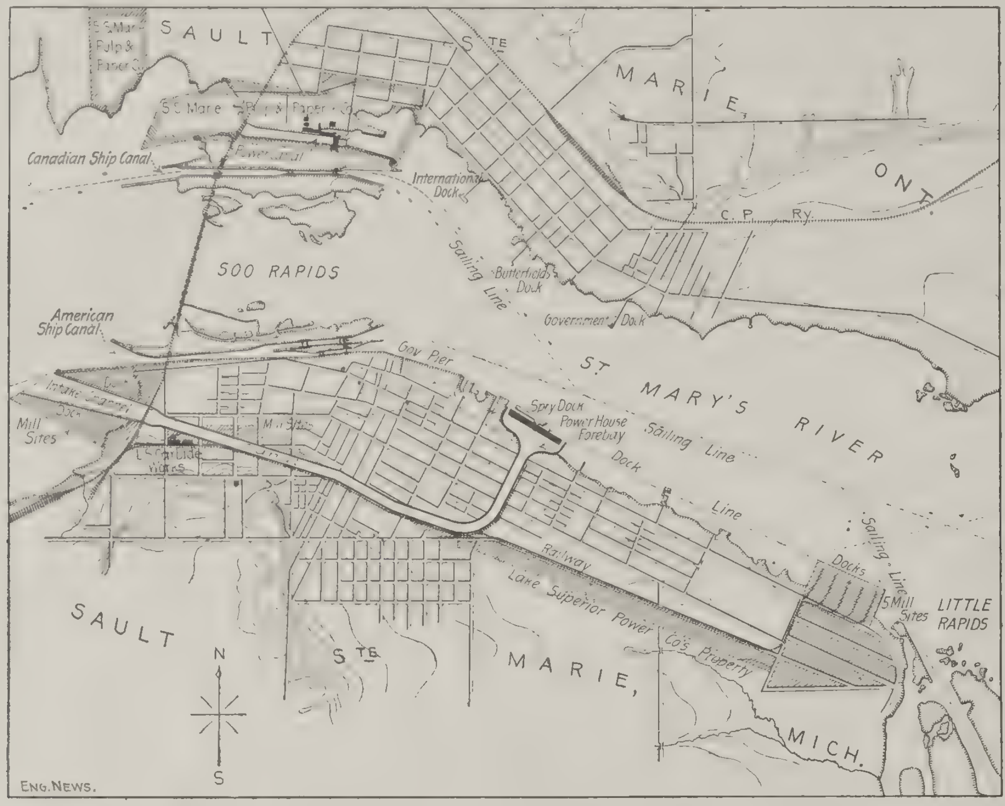

FIG. 1.—MAP SHOWING WATER POWER PLANTS OF THE LAKE SUPERIOR POWER CO., AT ST. MARY'S FALLS, MICHIGAN.

H. von Schon, Sault Ste. Marie, Mich., Chief Engineer.

The floor construction is shown clearly by Fig. 2. It will be noticed that the roadway and sidewalk have buckle plate floors with concrete filling, making a very stiff lateral bracing. The portion carrying the electric railway tracks has the ordinary floor beam, stringer and cross tie construction of railway bridges, but between each pair of the main floor beams, shown by Fig. 2, there is introduced an intermediate beam covering just the width of the railway tracks.

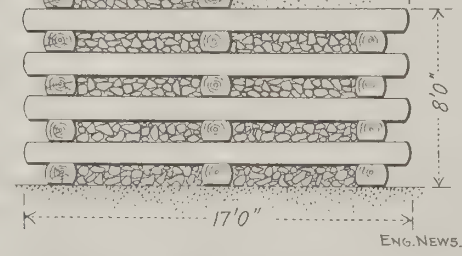

Fig. 2.—Retaining Cribwork for Banks of Intake Channel in Earth.

The method of erecting the bridge by falseworks is clearly shown by Figs. 6 and 7. These two engravings, made from photographs taken May 7 and May 18, respectively, also indicate the rapidity of erection. In about one month's time the three main spans were erected nearly complete, including the floor system and trolley tracks. Concerning the plan of erection, it will be noticed from Fig. 6 that the lower chords of the arches were first connected complete on the falseworks, including the bracing, and then the web members and upper chords were put in place panel by panel. This plan was found to be quicker and better, and was much easier on the falseworks, than the plan of erecting the bridge by putting in place a complete panel at a time, proceeding from one end to the other. It practically eliminated any pushing of the falsework due to loading one side first.

As an example of careful shop work, as well as for its rapid erection, this bridge is worthy of notice. Each arch is different, including all members, and although the metal work was not assembled in the shop before shipment the foreman of erection states that every joint and detail came together perfectly and without the least trouble.

In the foregoing, attention has been called very briefly only to the principal constructional features of this bridge, but a great many minor details of interest are shown by the drawings. For the matter from which this description and the illustrations have been prepared we are indebted to the Phoenix Bridge Co., Phoenixville, Pa., Mr. John Sterling Deans, M. Am. Soc. C. E., Chief Engineer.

◆

WATER POWER DEVELOPMENT BY THE LAKE SUPERIOR POWER CO., AT ST. MARY'S FALLS, MICH.

The possibility of utilizing the 18-ft. fall in the St. Mary's River at Sault Ste. Marie, Mich., for developing water power has long been recognized, and various different attempts have been made in the past to organize and carry out a broad plan of utilization. None of these plans reached a very advanced stage on the American side of the falls until recently, but on the Canadian side a large amount of work has been done during the past three years. The work of water power development on the Canadian side was first taken up, we believe, by the town of Sault Ste. Marie, Ontario. The town was, however, unable to raise the money necessary to carry the work to conclusion, and some four years ago it disposed of its interests to the Lake Superior Power Co., composed of a syndicate of Eastern capitalists, headed by the following officers: President, E. V. Douglas, Philadelphia, Pa.; Vice-President, F. H. Clergue, Bangor, Me.; and Treasurer, W. P. Douglas, Philadelphia, Pa. The company's headquarters are at 1420 Chestnut St., Philadelphia, Pa.

At about the same time, 1894, the same company secured the rights for water power development on the American side, but it first began the actual work of construction on the Canadian side. Here it completed a canal about 2,000 ft. long, 125 ft. wide, and 14 ft. deep, with all the necessary constructions for developing 20,000 HP. To use this power, two 40-grinder pulp mills were erected, one being completed in the fall of 1896, and the other during the following summer of 1897. The location of these mills, the canal and the other property of the company on the Canada side is shown by the map, Fig. 1, and this work will not be referred to again here.

On the American side of the river the work had, of course, been progressing in securing property and developing plans for the proposed improvement, but it was not until the present year that actual construction was begun. In fact the work might have been delayed still longer had it not been for the development of the calcium carbide industry. In 1896, Mr. Geo. O. Knapp, of Chicago, Ill., with the co-operation of the Lake Superior Power Co., erected at Sault Ste. Marie, Mich., the Lake Superior Carbide Works, for the manufacture of calcium carbide. This finally led to the organization of the Union Carbide Co., which controls the manufacture of calcium carbide over a large portion of the United States, and this company proposes to concentrate the manufacture of its commodity at Sault Ste. Marie. At the very outset, the company will require some 20,000-HP. (electrical) for its new works, and this power the Lake Superior Power Co. has contracted to supply. The remaining power to be developed will be largely consumed, it is expected, in the electrical reduction and concentration of the various copper and nickel ores in which the country to the north of the "Soo" is so rich. With this brief explanation, attention may be given to the plan proper for developing the water power of the St. Mary's River on the American side of the falls.

The St. Mary's River, as most of our readers know, is the outlet for the waters of Lake Superior into Lake Huron, the mean discharge at the rapids being about 90,000 cu. ft. per second. The mean elevation of Lake Superior is 601½ ft., while that of the river below is 582 ft., making a fall of 19½ ft. in a distance of about 3,500 ft. The general scope of the Lake Superior Power Co.'s project is to divert such a portion of the discharge over the most direct and economical route as will yield 40,000 HP. at the turbine shaft. To accomplish this it will excavate a canal through the village of Sault Ste. Marie, Mich., along the route shown by Fig. 1, and at its lower end erect a power house with the necessary turbines and electrical generators.

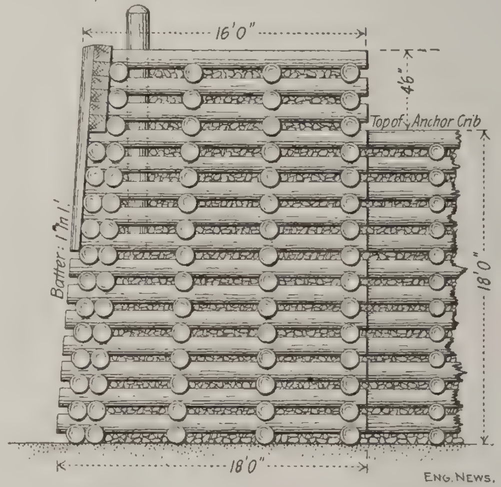

Fig. 3.—Bulkhead Wharf Construction at Entrance of Intake Channel.

Canal.

Location.—The right of way secured for the canal was primarily the location selected some ten years ago by one of the early companies organized to develop the water power of the river. In a measure, this early location, or a portion of it, is the logical one. The present canal location, therefore, follows the old location for about 6,000 ft., then curves to the north to an outlet. The old location continued nearly straight ahead, as shown by the dotted lines bounding the company's property, to an outlet some two miles or more below the falls. Fig. 1 shows clearly the present location.

The general location having been selected the next step was to determine the necessary dimensions of the canal. It was found that for about 3,000 ft., beginning at the west end, Potsdam sandstone came to the surface, and thence for the remaining distance the formation was sand, gravel, clay and boulders in undefined and irregular deposits, the sand, however, largely predominating. For nearly two-thirds of its length, therefore, the material penetrated by the canal would not endure undisturbed a velocity greater than 3 ft. per second. Such a flow would require a sectional area in the canal prism of about 10,000 sq. ft. or a width of canal of from 450 ft. to 500 ft. This width was out of the question. The land adjacent to the canal location had become settled and built upon, and the real or imaginary value fixed upon it by its owners, prohibited any thought of requiring much of it for right of way. The only solution was to narrow the canal and so protect its banks as to permit of a velocity of flow approximating that which could be safely maintained in the rock cut. This velocity was set at 7½ ft. per second.

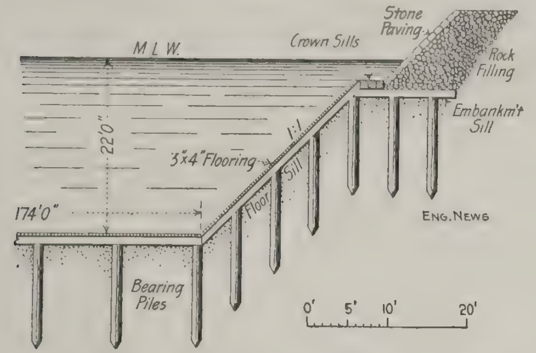

Fig. 4.—Revetment for Canal Prism in Earth.

The canal capacity was based upon the final development of 40,000 HP. on the shaft of turbines yielding 80% efficiency with seven-eighths water. The volumes of water required to be diverted to attain this result was $\frac{504{,}473}{Vh}$, in which V is the velocity of 7½ ft. and h is the effective head, which was found to be 16.2 ft., or a volume of 4,200 cu. ft. per second. Adopting an excess of area of 5% and the coefficient of friction, n, of 0.02, this made the necessary rectangular section in rock 200 × 22 ft. For earth, adopting an excess of area of 2½% and a coefficient of friction of 0.015, with side slopes of 1 on 1, the necessary section was 22 ft. deep, 174 ft. wide on the bottom, and 218 ft. wide at the top. These sections were, therefore, adopted for the main part of the canal; there being a widening at the head to form an intake and another at the foot to make a forebay.

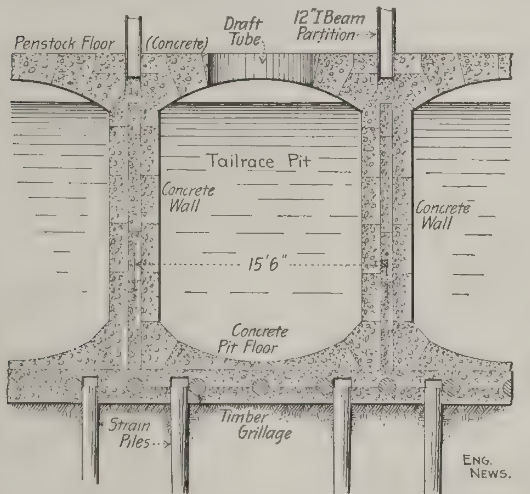

Fig. 6.—Cross Section of Tailrace Pit.

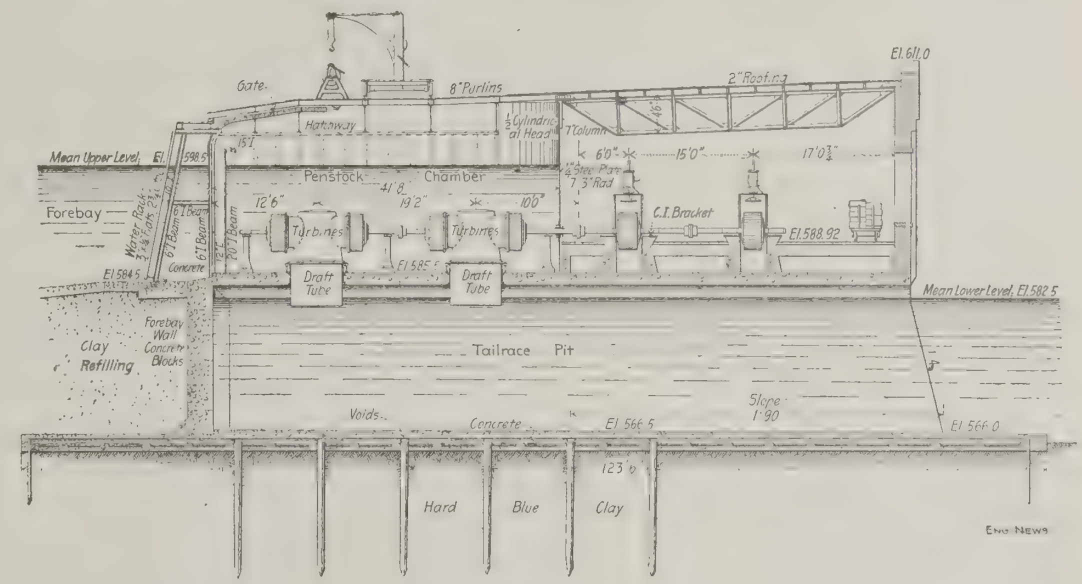

FIG. 5.—TRANSVERSE SECTION OF POWER-HOUSE THROUGH PENSTOCK AND TAILRACE PIT.

The intake is 2,400 ft. long and leads through a shallow bay to the navigable channel in the St. Mary's River. Here the prism is gradually widened to 500 ft., the sides being cribwork. The forebay at the terminal of the canal is about 1,400 ft. wide and is closed by the power house, as shown by Fig. 1.

For purposes of construction the work is divided into the Intake Section, Canal Sections I., II. and III., the Forebay and the Power House. The description of the work will follow the same order of division.

Intake.—The intake section extends from the harbor line on the west, east to the river shore, traversing Ashmun Bay, a shallow sheet of water generally from 3 ft. to 5 ft. deep. This section is about 2,400 ft. long, its eastern section being mostly in sandstone rock and the western section in sand, gravel and boulders. The rock portion is to be cofferdammed, and a rectangular channel 200 × 22 ft. is to be excavated dry. The western portion is to be gradually widened to 500 ft. at the entrance and dredged to a depth of 18 ft. The sides of the dredged channel are to be retained by log timber cribs with stone paved earth embankments, except near the western terminal, where bulkhead wharves 600 ft. long will be built.

The general construction of the retaining cribs is shown by Fig. 2, and is described more in detail in the specifications as follows:

The material is to be of hemlock, tamarack or Norway pine logs, faced on two sides to uniform thickness of 12 ins., laid in alternate longitudinal and transverse courses upon each other in crib form. The bottom course of the structure is a longitudinal of 12-in. timbers 30 ft. long, laid 7 ft. centers and is to rest on the channel bed in a horizontal plane, being 18 ft. below the datum plane. Upon it are laid transverse timbers 12 ins. thick and 17 ft. long, 7 ft. centers. The construction continues upward in this manner to a height of 8 ft. from the bottom, where it narrows, the upper four longitudinal courses consisting of only two rows of 12-in. timbers, the transverse timbers being 10 ft. long. The longitudinals in front and rear row are laid with butt joints and in center row pass by 7 ft. All timbers at crossings are spiked with ¾-in. × 20-in. drift bolts and all joints and laps are bolted every 2 ft. This construction terminates with a longitudinal course consisting of three 12-in. timbers laid close to the face of the crib, with top surface 16 ft. from bottom or 2 ft. below water surface, serving as heel sills for the stone paved bank, rising from this elevation to a height of 5 ft. above water surface on a slope of 1 on 1. The bottom transverse course in each alternate crib bay is floored with closely laid 12-in. logs, each spiked at crossing to each longitudinal timber with one ⅞-in. × 20-in. drift bolt. The cribwork is to be filled with stone ballast selected from rock excavation, no piece exceeding 1 cu. ft., and with chips and gravel to fill the voids between larger stones; and the back of the structure is to be filled with similar material to a height of 5 ft. above water surface. All this filling is to be in layers. The front slope of the filled space above the cribwork is to be paved with selected stones at least 12 ins. deep, set on edge by hand, close to each other, and so fitted that they will form a solid close-jointed pavement, resting at the foot against the toe log and being capped with larger flag stones all firmly imbedded into the bank.

The general construction of the bulkhead wharves is shown by Fig. 3, and is described in detail by the specifications as follows:

The bottom course of the structure rests on the channel bed in a horizontal plane, 18 ft. below datum plane, and is composed of four longitudinal 12-in. log timbers 30 ft. long, laid 5 ft. centers. Upon it are laid the transverse courses of 12-in. log timbers 18 ft. long and 7.5 ft. centers. The timbers in these two bottom courses are gained into each other at crossings 3 ins., so that the top surface of the transverse timbers is 1 ft. 9 ins. above foundation of structure. This construction continues upward except that all upper longitudinal timbers are 9 ins. thick, and that at crossings the transverse timbers only are gained for 1½ ins. The length of longitudinals is uniformly 30 ft. and they are laid butt to butt in front and rear rows, joints and splices are spiked with similar drift bolts set bolted to longitudinals; and they pass by 7.5 ft. in the two inner rows, being bolted to each other. Transverse timbers are of varying lengths as the construction goes upward, which is due to the face batter. All timber crossings are spiked with ¾-in. drift bolts 20 ins. long, and all joints and splices are spiked with similar drift bolts set from opposite sides and at intervals of 2 ft. This construction continues upward to 4 ft. 6 ins. above upper level, with the exception that the front row of longitudinals above water surface is of square-sawed white pine facing timbers.

The bottom facing timbers are 12 × 12 ins. × 26.5 ft., laid with 4-ft. scarf joints on bevel face to follow face batter and upon them are laid four courses of 10 × 12-in. × 30 ft. 8 ins. or 40 ft. long on 12-in. faces with butt joints. The cap facing timber is of 12 × 12 ins. × 34 ft. or 40 ft. long laid with 4-ft. half lap joints. All scarf and lap joints are tied by two 1 × 14-in. drift bolts; and facing timbers are secured to each other by ⅞-in. drift bolts of sufficient length to set through 2½ timbers, driven every 4 ft. The front ends of the transverse timbers above water surface are to be dovetailed into the square facing timbers, the dovetails to be not less than 6 ins. deep by 8 ins. wide, neatly cut, leaving square cut sawed shoulders on the ties and to fit up well against the facing timbers. The dovetailed ends are secured to the facing timbers, each with one ¾-in. round-pointed drift bolt, 16 ins. long. Half-round oak fenders are placed on each side of the exposed ends of the crossties, the top of fenders being flush with top of bulkhead. Mooring posts are placed in bulkhead every 50 ft. A close log floor is laid in each alternate crib bay upon the second longitudinal course from the bottom.

Five anchor cribs 20 ft. long (transversely), 22.5 ft. wide (longitudinally) and rising to water surface, are placed in rear of the main bulkhead. Their construction is the same as that of the main bulkhead, consisting of alternate longitudinal and transverse log timber courses. There are four longitudinals, 5-ft. centers, 24.5 ft. long, and four transverse timbers running through from front face of main bulkhead to rear of anchor crib in one length. These courses are laid and joined in the same manner as described for the main bulkhead and are all floored on the second longitudinal course as described for alternate bays in the main structure; two anchor piles are to be set in each unfloored bulkhead bay against the rear longitudinals, and stone ballast is to be placed in the entire bulkhead structure.

The work of excavation proper in the intake section calls for brief mention only. As stated, the western portion is dredging. The eastern portion inside the cofferdam is dry excavation in rock, overlayed by sand, gravel and boulders. There will be about 115,000 cu. yds. of solid rock and 152,000 cu. yds. of other material in this dry excavation. In rock the sides of the prism are to be cut with channelling machines.

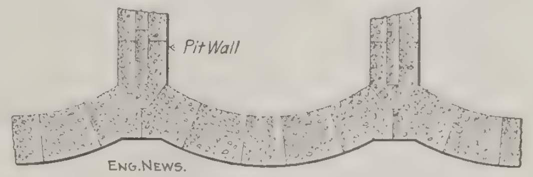

Fig. 7.—Horizontal Section Through Forebay Wall.

Canal Sections I., II. and III.—This portion of the work consists of the following excavation:

Section.	Dimensions of prism, ft.	Length, ft.	Not rock, cu. yds.	Rock, cu. yds.
I.	200 × 22	2,900	23,000	532,000
II.	22 × 174 and 218	2,900	710,000	......
III.	22 × 174 and 218	3,100	780,000	......
Total		8,900	1,513,000	532,000
Grand total of excavation				2,045,000

Besides excavation, this work comprises the necessary constructions for retaining the banks. In the rock portion this consists in constructing a retaining wall 3½ ft. wide at the bottom, and 2½ ft. wide at the top, where the top of the natural rock falls below the requisite height of the canal banks, and in remedial construction to be applied to the canal sides where the rock formation is found to be faulty. It is estimated that there will not be more than 350 cu. yds. of retaining wall.

The protection of the earth prism will consist of a timber revetment on the bottom and sides, constructed as shown by Fig. 4. The bearing piles are driven in rows spaced 5 ft. apart, and running transversely across the canal, and they carry log timber sills faced to a uniform width of 12 ins. and drift bolted to each pile. The space between sills is filled with puddle. On top of the sills is laid a floor of 3 × 4-in. timbers. The other details of construction are sufficiently explained by the drawing, Fig. 4.

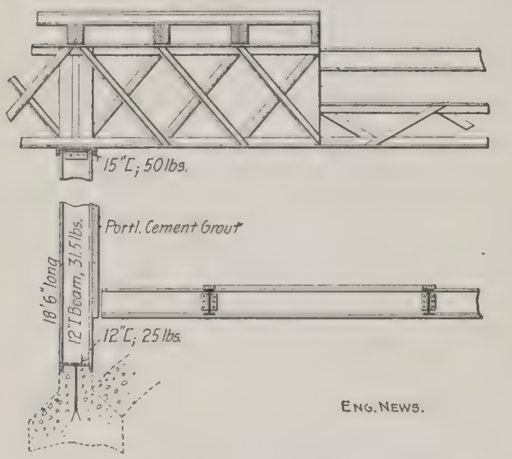

Fig. 8.—Part Longitudinal Section Showing Penstock Construction.

Forebay.—The forebay consists of the gradual expansion of the channel at the termination of Section III. by similar curves east and west to a width of about 1,400 ft. The length varies from 150 ft. to 300 ft. The power house closes the front of the forebay. The whole area of the forebay will be inclosed by triple-lap sheet piling, and its banks will be riveted in a manner similar to the earth sections of the canal proper. The amount of excavation called for, including that for the power house foundations, is 235,000 cu. yds. of mill waste, sand, gravel and clay.

Power House.

Foundations.—The foundation area of the power house is about 1,367 ft. × 125 ft., and the foundation consists of a timber grillage placed upon a bed of stiff clay and resting upon piles. A row of triple lap sheet piling surrounds the grillage, which is also filled and covered with concrete to a depth of 6 ins. above the tops of the log caps. This construction is shown in a general way by Fig. 5, which is a transverse section of the power house through the center of the penstock and of the tailrace pit underneath it. This section also shows the arrangement of the turbines and dynamo coupled to a single horizontal shaft, and it may be stated here that there are 85 of these units in the power house.

Tailrace Pits.—Upon the timber grillage foundation are erected the pit walls 3 ft. thick and 15½ ft. apart c. to c. These walls extend for 96 ft. transversely across the foundation grillage. At the bottom between the walls are sprung inverted arches forming the pit floors, and at the top is the roof, which is a series of circular arches with spans of 12½ ft., rises of 2 ft. and a thickness at the crowns of 1½ ft. This roof has circular openings lined with steel collars for the turbine discharge, and covers only 43 ft. of the pit length, or the length of the penstock chambers. The inner ends of the tailrace pits are closed by an arched forebay wall 18 ft. high. In this manner the tailrace pits are entirely enclosed except at their outer ends, where the water is discharged. Fig. 6 is a transverse section of one of the tailrace pits showing the wall, floor and roof construction just described, and Fig. 7 is a horizontal section of a small portion of the arched forebay wall closing the inner ends of the pits.

The construction of the pit walls, forebay wall and pit roof is of Portland cement concrete blocks laid in cement mortar, and that of the pit floors is monolithic Portland cement concrete. Altogether about 28,500 cu. yds. of concrete are required in the work, of which 23,739 cu. yds. will be in 14,400 blocks. The use of so much concrete block masonry in rather trying positions makes the specifications for the cement employed of more than usual interest, and their principal requirements are abstracted here:

The inspection of the cement will be in 100-barrel lots. Ordinarily cement will be taken for testing purposes from 10 barrels out of each 100 lot, selected at random, and the failure of any of this cement to come up to all the requirements will be considered sufficient cause to reject the lot of 100 barrels of which the faulty cement is a part. The inspection tests to which the cement is to be subjected will be made as follows:

(1.) To determine the time of initial setting cement will be mixed for three minutes with about 30% of water so as to make a stiff paste and then spread upon a glass plate to a thickness of about 1½ ins. Whenever this cement paste resists a slight pressure exerted by a finger nail it will be considered to have taken the initial test.

(2.) To determine the constancy of volume mixed neat cement will be made into wedge-shaped pats about 3 ins. on a side, ½-in. thick at back and tapering to a feather edge. This pat will be kept in a box protected from draft or sun and covered by a wet cloth for 24 hours and then laid in water of ordinary temperature where it will be kept and examined for a period of 28 days.

(3.) To determine the fineness the cement will be sifted through a No. 100 sieve; that is, 100 holes per lin. in.

(4.) To determine the tensile strength 20 briquettes of the cement lot to be tested, 10 of neat cement and 10 of three parts of standard Point Aux Pins sand, will be made and tested in accordance with the methods approved by the American Society of Civil Engineers as far as they relate to the preparing, preserving and breaking of the briquettes.

The requirements to be fulfilled by the cement in order to be accepted for this construction, as evidenced by the results of the inspection tests, are:

(1.) That the time of initial set is not less than one hour.

(2.) That the cement pats made for the constant volume test, exhibit no warping, cracking or other unsoundness after being in air or water of ordinary temperature for 28 days.

(3.) That the cement is of such fineness that at least 90% will pass a No. 100 sieve.

(4.) That the minimum tensile strength per sq. in. as per average of ten neat cement briquettes after 28 days of age (1 day in air and 27 in water) shall be 700 lbs., and of the three parts of sand briquettes of the same age and exposure, 300 lbs.

In regard to the manufacture of the concrete blocks the specifications are as follows:

The filling of the molds is to be done in molding sheds as close to the point where the concrete is mixed as practicable. The molds may be of any construction the contractor selects, provided they are of the true forms and dimensions required for the blocks and that they are lined with sheet iron on the inside. They may be bottomless provided they are placed upon sufficiently heavy and smooth platforms. Before the concrete is deposited in the molds each part of the mold which will come in contact with the concrete is to be thoroughly cleaned and covered with a thin coat of a good grade of machine oil. The molding of any one block must not be interrupted but is to be completed as rapidly as practicable without any intermission in the depositing and compacting of the concrete. The exposed surfaces of the block are to be molded out of the finer material contained in the concrete mass and this is to be compacted by special steel-shod oaken rammers having a face of ½-in. × 5 ins. The filling is to be carried slightly over the top surface of the mold and a cover sufficiently heavy is to be forced upon the top so that the surface becomes perfectly leveled off and smoothed. A cement label in accordance with the engineer's directions is to be inserted in the top of each block upon its completion. The sides of the mold may be removed 48 hours after the block is molded but no sooner, and the block is to remain upon the molding platform at least 15 days, during which time it must be shaded from sunlight, kept wet by sprinkling, and protected against freezing temperature. After this period blocks may be removed to storage where they may be piled provided they rest on 2-in. planks and they are to be protected from weather and temperature below 36° F. for 15 days more. Blocks which have attained an age of 30 days and are accepted by the engineer may be laid in the structure for which they are designed.

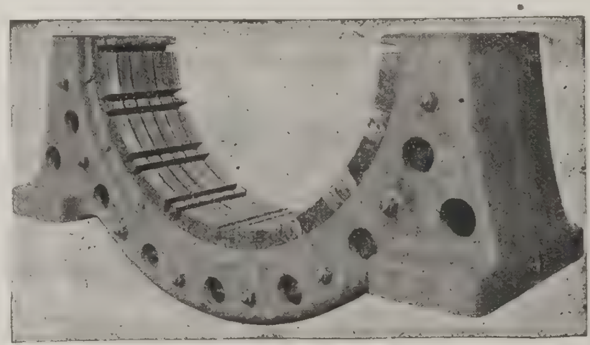

Fig. 10.—Lower Half of Stationary Armature for Single-Phase Alternating Current Generator.

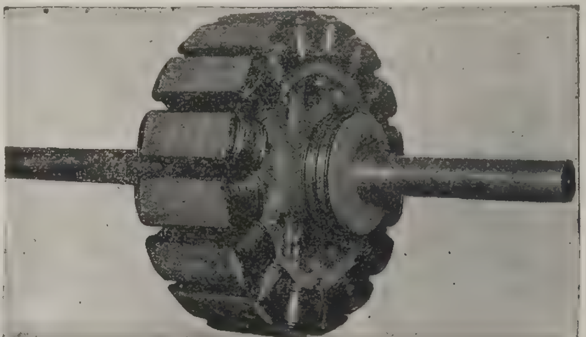

Fig. 11.—Rotating Field for 375 K-W. Alternating Current Generator, Built by the Walker Co., Cleveland, O.

The laying of the concrete blocks will be in all respects governed by such rules and methods as are usually adopted in laying first-class ashlar masonry.

Penstock.—The penstocks are located directly over the rear ends of the tailrace pits, as shown by Fig. 5, and consist of a floor, which is also the roof of the tailrace pit below, partition walls, cylindrical steel bulkheads closing the inner ends, and a trussed roof. Fig. 8 shows the partition wall, floor and roof construction, and Fig. 9 shows the bulkhead construction. It will be noted that the partition walls consist of a framing of I-beam posts with channel sills and caps filled with Portland cement grout. This filling will be done between timber forms having a clear inside width of 1 ft. 5 ins.

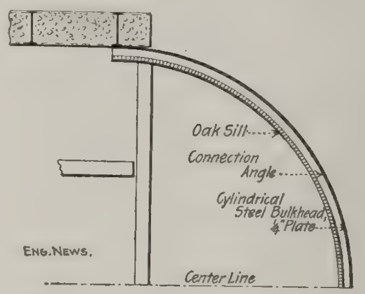

Fig. 9.—Horizontal Section Through Penstock Bulkhead.

The bulkhead is semicircular and is fastened to the walls and floor, as shown by Fig. 9. It is 14 ft. 6 ins. in diameter, and is made of ¼-in. steel plates connected by double riveted lap joints. The ends of the penstocks opposite the bulkheads are open into the forebay. Five of the penstocks are also arranged for spillways, and have a discharge capacity equal to the full amount of the water diverted by the canal.

Each penstock is closed by a rolling gate of the construction indicated by Fig. 5, and has a water rack to prevent the access of drift. A movable headgate of the wicker dam type will also be erected at the terminal of the canal proper, its superstructure being a highway bridge.

Mill.—The mill proper occupies the front portion of the power house, and contains the electric generators. The two pairs of turbines in each penstock have a capacity of 500 HP. at 250 revolutions. These are mounted on a single horizontal shaft, to which the 375-K-W. slow motion dynamo is also attached.

These generators, which are to be built by the Walker Co., Cleveland, O., operate at 200 volts and 60 cycles per second when running at 240 revolutions per minute. Ten exciters of 100 HP. each will be installed, and these will be belted to the turbines in such manner that each exciter can be operated by either of two turbines. The generators have stationary armatures, as shown in Fig. 10, with an interior revolving field magnet, which is a massive cast-iron split hub provided with steel ring tires, to which are bolted the 30 outwardly projecting laminated pole pieces. These are wound with a flat copper ribbon conductor, wound edge on, and insulated with shellacked paper. The winding is placed upon a suitable spool which is slipped on the pole piece and securely clamped when the pole piece is bolted down. These bobbins are connected in series, the ends running to the two rings, seen in Fig. 11, which permit the exciting current to reach the coils while the field is revolving. The armature consists of a large ring built up of sheet iron stampings, notched to form slots for the armature coils. These sheets are clamped together in semi-circular cast-iron side pieces, which are hollowed for ventilation, and the two halves are finally bolted together. The armature coils are wound on forms and carefully insulated, being afterwards slipped into slots, clamped into place and connected up. The current will be used in the carbide furnaces, consisting of 6 furnaces in multiple on four machines, and as only four furnaces out of the six will be in use at any one time, each furnace will take the full output of a machine, or about 1,800 amperes at 200 volts.

The mill house proper is built of sandstone masonry, with a steel truss roof and steel interior framing. Fig 5 shows this construction in a general way.

In conclusion it may be interesting to some of our readers to give the total amounts of the different kinds of work and material which will be required in constructing the plant. They are as follows:

Excavation:	
Solid rock, cu. yds.	650,000
Other material, cu. yds.	2,200,000
Log timber, ft., b. m.	15,000,000
Squared timber, ft., b. m.	7,000,000
Structural steel, tons	2,400
Bolts and spikes, tons	300
Portland cement, barrels	70,000
Sandstone masonry, cu. yds.	40,000
Sand, cu. yds.	25,000
Brokenstone, cu. yds.	60,000
Turbines	320
Dynamos	80

According to the present plans, all work of construction is to be completed in two years. All the plans and specifications of the work have been prepared under the direction of Mr. H. von Schon, Chief Engineer, Lake Superior Power Co., Sault Ste. Marie, Mich. We are indebted to Mr. von Schon for the information from which this description has been prepared, and also to "The American Electrician" for Figs. 10 and 11 and the material from which the description of the electrical apparatus was prepared.

* * *

THE WALKER CONDUIT ELECTRIC STREET RAILWAY SYSTEM.

The satisfactory working of the Metropolitan conduit electric railway in Washington, D. C., and the Lenox Avenue line in New York city, marked a new era in city street railway construction. The system thus practically tested has undoubtedly come to stay, because it meets the engineering requirements and also embodies the one feature long desired by municipal authorities, namely, freedom from any overhead construction.

The two roads just mentioned have now been in operation about three years, and their continued success is a final answer to the stock statement that conduit roads cannot be made to operate successfully or economically. As a result, we may expect to see many city street railway companies following the example of the Capital Traction Co., of Washington, or the Metropolitan, of New York, and either of their own accord, or under compulsion by city authorities, change their lines from horse, cable or overhead trolley to the conduit system.

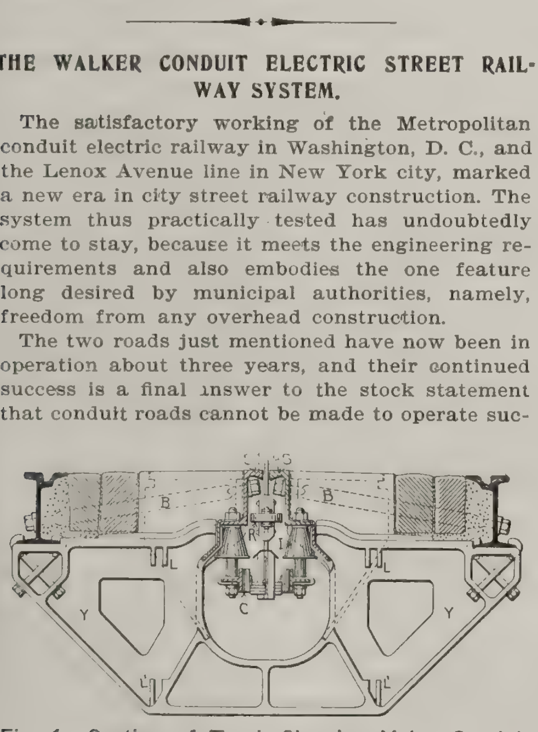

Fig. 1.—Section of Track Showing Yoke, Conduit Insulators and Plough

Anticipating this demand, likely to occur in the near future, the Walker Co., of Cleveland, O., has developed a conduit system embodying the successful features of the present systems and introducing such new ideas as experience has made expedient.

To the casual observer the conduit of this system appears the same as those first mentioned; substantial cast-iron yokes spaced about 5 ft. apart support deep girder rails and the usual slot rails. Inside the conduit are two T-shaped conductor rails, about 6 ins. apart and 14 ins. below the street surface, while every 15 ft. are the familiar cast-iron hand-hole lids.

Fig. 1 represents a section of track using the Walker conduit construction. The yokes, Y, are cast with large broad steps, but are light in weight, owing to the method of distributing the metal, the webs being cast thin, but deep. They are all of the same pattern, thus preventing any delay during construction work which would result from waiting for special yokes. Suitable steps are provided at the ends for supporting the rails, which are securely locked into place by hook bolts, as seen in the figure. The slot rails, S, S, are bolted to the yokes in the usual way and are braced by the flat tie rods, B, B. The insulators, I, I, Fig. 2, consist of an outer bell-shaped malleable iron shell and a straight steel shank threaded at the lower end and held in the bell by an insulating material, said to be superior to porcelain on account of its elasticity. This is formed around the knob of the rod and shoulder of the bell by pressure. These insulators are bolted to the foot of the slot rails a little to one side of every third yoke, that is, 15 ft. apart, and a cast-iron hand-hole frame, Fig. 3, is bolted to the slot rail and the yoke in the proper position to afford access to the insulator. To the lower end of these insulators the conductor rails, C, C, are bolted, the bolts passing through the web of the conductor, thus avoiding the long cast-iron offset heretofore used. These T-rails are 3 × 2½ ins., and have a cross section of about 250,000 circular miles. They weigh 18 lbs. per yd. and are rolled in 30-ft. lengths, thus bringing a joint at every third hand-hole, where two No. 0000 copper bonds are employed. The line is divided into insulated sections, varying from 500 to 800 ft. in length, which are connected together by a system of switches placed in suitable manholes under or at the side of the track, so arranged that any trouble can be easily located and confined to a short section of the line. Taps are taken off from the feeders at frequent intervals, and these are also controlled by switches.

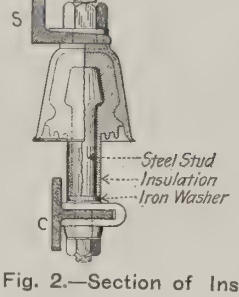

Fig. 2.—Section of Insulator for Supporting Conductor Rails.

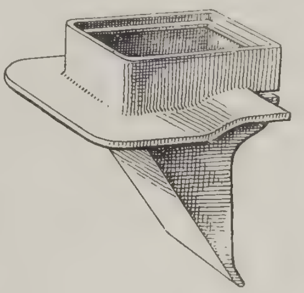

Fig. 3.—Cast Iron Handhole for Access to Insulators.

Construction work is facilitated by the lugs, L, L, cast on the yokes, into which boards are slipped to form a backing for the concrete of the conduit. In this way just the proper thickness of material is maintained with no waste. To prevent any possibility of the breaking-in of the concrete forming the arch at the top of the conduit, steel plates, shaped in rolling so as to hang on the foot of the slot rail and rest upon suitable lugs cast upon the yokes, are employed. The finished conduit is 16 ins. wide and 24 ins. deep from the upper surface of the slot rail to the bottom.

The plough employed, shown in Fig. 2, differs only in details from that used on the systems now in operation. It consists of two ¼-in. steel plates, bolted together, at the lower end of which are bolted two pieces of wood about 18 × 6 ins. by about ⅞-in. thick. The cast-iron contact shoes are mounted upon springs, as shown, and are connected through copper fuses to the leads, which run up in grooves between the steel plates to contact strips on an insulating block, H, at the top. Just where the hanger would wear against the sides of the slot tempered steel pieces are inserted. A few inches below this, two rollers are strongly mounted upon the hanger, their purpose being to bear against the foot of the slot rail, as seen in Fig. 1, and thus prevent any great strain on the conductor rails in rounding curves, or should the car run on a switch or off the track. To attach the plough to the car, a cast-iron clamp bar is bolted to the steel plates previously mentioned. This is proportioned so as to have ample strength under ordinary working conditions, but will break from any undue strain and permit the plough to drop free of the car. To facilitate this, connection from the car to the plough is made through a box, J, provided with contact springs which press against the strips on H. If the plough drops or it is desired to break connection the box is slipped off.

Comparing the section given in Fig. 1 with the section of the conduit roads now in use (Eng. News, Feb. 24, 1898, Fig. 4), several differences will be observed. The first, and possibly the most important, is the substitution of a molded compound in the insulator in place of porcelain, thus considerably reducing the size. The second, resulting from the reduction of size, admits of the insulator being bolted to the foot of the slot rail, thus saving the boring of one hole and the use of two bolts for each insulator, and lastly, as the insulators are now close together, the cast-iron offset is dispensed with, thus effecting a saving to that amount. The insulator stud is bolted directly to the web of the conductor rail, practically at its center of gravity, and consequently the strain on the insulator is simply the dead weight of the conductor rail, except when a car is passing. At such times there is a side strain due to the pressure of the plough springs.

A WATER TANK AT DALLAS, TEX., is reported as having failed on Aug. 1, fatally injuring a man engaged in finishing it. The tank was to be used for private fire protection and was on a tower 65 ft. high. It had a capacity of about 30,000 gallons and had just been filled.

ELECTRIC LOCOMOTIVES for operating the mountain divisions of the Central Pacific Ry. are said to be under consideration. It is believed that sufficient water power can be obtained from the mountain streams in the vicinity of the line to generate the current, and it is proposed to operate the road in this way from Sacramento east across the Sierra Nevadas to Verdi, Nev., a distance of 144 miles. While the above is only newspaper rumor, the high price of coal on the Central Pacific makes the story one which is not at all improbable.

SUBSCRIPTION RATES: United States, Canada and Mexico, One Year, $5.00; 6 *months,* $2.50; 2 *months,* $1.00. *To all other countries in the Postal Union: Regular Edition, One Year,* $7.60 (31 *shillings*); *Thin Paper Edition, One Year,* $6.31 (26 *shillings*). *SINGLE COPIES of any number in current year,* 15 *cents.*

Mailing addresses may be changed at will by sending both old and new address. The number on the address label of each paper indicates when subscription expires, the last figure indicating the year and the one or two preceding figures the week of that year; for instance, the number 328 *means that subscription is paid to the* 32*d week (that is the issue of Aug.* 11) *of the year* 1898; *the change of these figures is the only receipt sent, unless by special request.*

ADVERTISING RATES: 20 *cents per line. Want notices, special rates, see page* 18. *Rates for standing advertisements sent on request. Changes in standing advertisements must be received by Monday afternoon; new advertisements, Tuesday afternoon; transient advertisements by Wednesday noon.*

We noted in our last issue the issue of a supplementary circular by the Navy Department announcing that in considering bids for the three new battleships, preference would be given to designs promising the highest speed, in connection with good steaming radius. Apparently the Navy officials have come to feel, however, that this plan will not give the new vessels such speed as they should have to keep the country abreast of foreign nations, and according to Washington dispatches of Aug. 1, Secretary Long has proposed to the Board of Construction that the present call for bids should be withdrawn, and entirely new designs should be prepared which will give the ships greater speed.

It is said that the Board itself is now in favor of this, and that the new vessels will be designed for a minimum speed of 18 knots instead of 15 as at present, will be copper sheathed, and will have a displacement of about 13,000 tons. The cost will be somewhat increased; but it is hoped that Congress will consent to an increased appropriation when it reassembles.

If this plan is carried into effect, the country will have renewed reason for its confidence in Secretary Long as the most able head that the Navy Department has had in many years.

◆

The accuracy of the shop work habitually turned out by some of the better bridge shops of this country is sometimes, it seems to us, not so fully appreciated by engineers as it might be. As an instance of such careful workmanship we may call attention to the three-span steel arch bridge across the Schuylkill River, in Fairmount Park, Philadelphia, Pa., which is quite fully described elsewhere in this issue. The fact that in a structure of this magnitude where each arch differed in all its members, and without any previous assembling of the different parts, every joint and detail was found to fit perfectly upon erection speaks marvels for the perfectness of the shop management and machine work of the modern bridge shop, and it should not fail to receive full recognition. This is, however, by no means an isolated example. Among several which we now call to mind may be mentioned the new 840-ft. steel arch which is being built at Niagara Falls, N. Y., to replace the old footway suspension bridge just below the cataract. The closure of this arch, which took place on April 17, was a notable illustration of careful planning and shop work on the part of the builder, as well as the engineer.

As stated in Engineering News of Feb. 10, 1898, the two halves of the Niagara arch were erected simultaneously from the opposite shores, each half-arch being held back to its adjacent shore by a system of temporary anchor rods attached to alternate panel points of the arch rib until the final connection at the center ensured the stability of the structure by itself. The top anchor rods, that is, those reaching to the panel points nearest the center or crown of the arch, were made strong enough to hold the entire weight of the bridge with the other anchor rods removed, and it was calculated in designing the center connection of the arch ribs that with the weight carried by these top anchor rods alone there would be an opening at the center between the ends of opposite ribs of 2½ ins., at normal temperature. As a matter of fact the amount of this opening proved to be 2¾ ins., with a temperature of 60° F., when the closure was made. Fully as accurate results were obtained in other respects. The arch being of the two-hinge type, with the top chord under a compressive strain, the ends of the top chord were of course the first to close, to be followed by the closing of the arch ribs proper as the strain in the top chord changed from tension to compression under the load. It is plain that if the top chords were thus allowed to close first there might be some difficulty in getting the arch rib to close, and, further, there would be much uncertainty whether the proper apportioning of the strains between the top chord and the arch rib had been secured.

To avoid all this, the builders decided to insure the arch ribs meeting first by the simple means of cutting off the top chords and then, after the ribs had been connected, to force apart the opening in the top chord and insert a cast-steel shim just long enough to replace the metal previously cut off. The various dimensions and pressures involved in this process of closing were carefully calculated at the bridge works before erection and were outlined in a letter of instructions to the company's engineer in charge of erection as follows:

> Each top chord has been made 3 ins. shorter than the figured theoretical length. This would leave in the structure if under no strain whatever, an opening of 6 ins. After the anchor bars have been relieved of all strain and the ribs and their bracing are carried as a three-hinged arch, with a pin at the lower center, this distance ought to be shortened, at an average temperature, by 2¼ ins., leaving a 3¾-in. opening. The weight of the anchor bars which will be carried by the arch will probably increase this opening somewhat. Every rise in temperature of 10° F. will increase the space by 0.2-in. and vice versa. To change the three-hinged arch to the two-hinged arch, the opening at the center ought to be forced back again 2¼ ins., giving a total opening of 6 ins., as intended in the drawings. To do this it will take 370,000 lbs. on one rib, at the average temperature. For every rise in temperature of 10° above the average this strain ought to be reduced by 34,000 lbs. on one rib, which amount corresponds to 0.2 ins. mentioned above. We expect thus, if a pressure is applied, which makes the proper allowance for the temperature, that we will be able to close up the top chords of our arch by planing down 6½ ins. permanent cast-steel shims to 6 ins. or to the amount corresponding to what the top chords have been kept short.

When the closure was made on April 17, the arch ribs came together within ¼-in. of the calculated distance, as stated above. The opening between the ends of the top chords at 60° F., was exactly 3¾ ins., and the pressure registered by the hydraulic jacks in forcing this opening apart the full 6 ins., was 370,000 lbs. for each chord. The lateral adjustment was easily made with crowbars. In other words, the results were almost exactly what they were figured to be. When it is remembered that the accuracy of closure depended, first, upon the accuracy of the calculation and design of the entire steel work; second, upon the exactness with which the bearing shoes or skewbacks were placed, and, third, upon the perfection of the shop work, these results are indeed wonderful. We are not forgetful of the fact that in structures of this immense size and importance the builders doubtless exert themselves particularly, to secure phenomenal results in such particulars as those just described; but nevertheless the combined cunning and efficiency of men and tools which produce these results is an element which does not disappear in the every-day work turned out by them. Where so much important work is left to the honesty and ability of the bridge manufacturer, as is habitually done in this country, this is a matter of no small gratification.

◆

The exact function of bacterial analyses of public water supplies is becoming better understood as time passes and experience accumulates. Unfortunately, many engineers, the majority of doctors, and nearly all laymen still hold mistaken ideas on the subject. We have frequently urged that the isolation of any specific disease germ from the other bacteria in water is a task so difficult and uncertain as to render the attempt practically worthless to the water-works manager. The best bacteriologists freely admit this now, it being a general rule that the higher a bacteriologist stands in his profession the less pretension he makes to being able to differentiate the typhoid bacillus. Thus, Prof. Percy F. Frankland, who has, perhaps, done more than any other man in England to make known and appreciated the value of bacterial examinations of water and the bacterial efficiency of filtration, says

> it is becoming daily more evident that the recognition of specific bacteria is a matter of much greater difficulty than was at first supposed, and the bacteria which are associated with typhoid and cholera are amongst those which offer the greatest obstacles to complete identification.

This quotation is from a paper on "The Chemical and Bacterial Examination of Water," read by Prof. Frankland before the recent meeting of the British Association of Water-Works Engineers. In studying the character of water supplies it is very true, as Prof. Frankland says, in concluding his paper, that

> it is not only necessary that a particular sample of it submitted to an expert shall be free from danger, but that it shall be derived from a source which is capable of continuously yielding, year in, year out, a safe and wholesome product, and in order to secure this end he will have to make use of all the independent evidence which is available: (1) That which is obtained from careful inspection of the source; (2) that which can be furnished by chemical analysis; and (3) that which is afforded by the bacteriological examination of the water. And the special value of the bacteriological evidence will consist in the power possessed by this method of examination alone of revealing whether and to what extent any purification processes, natural or artificial, are able to remove disease-producing bacteria, should they at any time be present, from the water.

We do not intend to belittle the work of the bacteriologist. His services are valuable in studying natural waters and invaluable in determining the efficiency of filter plants which treat polluted water. Single analyses, of any kind, are of comparatively little use, while bacterial analyses of filtrates should not only be made frequently, but samples from each bed should be examined in order to determine whether each unit of a plant is doing its work properly. A fully equipped and well-manned bacterial laboratory is a desirable, if not necessary, adjunct of every filtration plant, and for certain waters a chemical and microscopical laboratory should also be in service. Where water is not purified, one or all of these laboratories can also be maintained to great advantage, but should be supplemental, in most cases, with frequent and searching sanitary inspections of the drainage area from which the water is derived. This latter work, as Prof. Wm. T. Sedgwick recently pointed out, would be a proper and profitable field for young engineering graduates.

◆

THE POSITION OF UNITED STATES ASSISTANT ENGINEERS.

As most of our readers know, the work of the United States Government on its fortifications for coast defence and on the improvement of its navigable rivers and harbors is under the charge of the officers of the Corps of Engineers of the Army. This corps is made up of those graduates of the West Point Military Academy who stand highest in their classes at graduation; and while it might be thought that special aptitude in engineering studies might be a better basis of choice than the mere attainment of a high standard according to the West Point marking system, it must be confessed that the plan of selection has worked admirably in practice.

The total membership of the corps is now, we

FIG. 3. ELEVATION SHOWING STRAINS AND COMPOSITION OF ARCH MEMBERS.

MOUNT PARK, PHILADELPHIA, PA.

Designed and Erected by the Phœnix Bridge Co., Phœnixville, Pa.

believe, about 115; including the officers of every grade, and by a recent law it is to be increased to 127. It is manifest, however, that this number of engineers is wholly inadequate to perform the engineering work required in connection with the expenditure of the many million dollars which are laid out by the Government each year, on rivers, harbors and fortifications, and in carrying out other work such as that of the lighthouse board, which is entrusted to the Corps of Engineers. The officers in charge, therefore, have power to hire draftsmen, clerks, transitmen and various other assistants upon the works under their charge. Those entrusted with the most responsible work are given the title, U. S. Assistant Engineer. The number of such Assistant Engineers employed by the Government during the last fiscal year was about 180.

The subordinate title and inadequate pay of these assistant engineers have long been a source of serious complaint, and many years ago there was considerable agitation on the part of some of the local engineering societies in the West looking toward a reorganization of the system of conducting Government works. This agitation came to nothing, however, one reason being that the reforms proposed involved such radical changes as to arouse opposition, and the position of the United States Assistant Engineers remains what it has been for many years past.

The present time seems to us an opportune one to consider the position of these engineers and see what can and ought to be done to better it. It is by no means unlikely that the next half-dozen years may see the undertaking by the Government of public works of great magnitude, demanding for their most successful design and execution the highest grade of engineering ability. Engineers as a body must recognize the great desirability that the Government should secure such ability, and accord to those who furnish it such credit as they may deserve, and a monetary compensation that will serve as some standard in fixing the value of the highest class of engineering work in this country.

Under the present system we think every fair-minded man must concede that the Government falls far short of doing this. The pay of the 180 assistant engineers varies from $125 to $300 per month. They are hired and discharged as the work requires, and a large proportion of them are employed only a small part of the year. The highest salary named is paid to a very few of the men. We find only 68 with salaries of $200 or over, and only 13 with salaries of $250 or over. When the temporary character of the employment and the difficult and important nature of the work is considered, we contend that these salaries are inadequate in many cases for the high-class of professional ability that is needed.

It may be said that these engineers are not obliged to accept Government situations. If the compensation is inadequate, they can seek work in other fields; but such a comment betrays want of knowledge of the real state of affairs. A large proportion of these assistant engineers, if they are to perform the tasks assigned them as they ought, must devote years to study and practice in the special field of river and harbor engineering. The engineer who masters this science and becomes a thorough expert in this branch of the profession has absolutely no prospect of employment in this country except in the Government service; and the utmost that he can hope for in the Government service is employment of uncertain duration from month to month, at a compensation of at most $200 or $300 per month. Because an engineer accepts such pay does not prove that it is adequate. He may well prefer it to the alternative of seeking a subordinate position in some other branch of the profession, where his expert knowledge, so hardly acquired, would be of little or no value; but the fact that the Government has no competition in the employment of engineers on works for the improvement of navigation ought not to be taken advantage of to cut down their pay.

The fact is that when the temporary character of the employment is taken into account, there are, we believe, not a few clerks in the U. S. Engineer offices who are better paid, on the whole, than the assistant engineers. Indeed, for employees of the lower grades, such as clerks, stenographers, ordinary draftsmen, etc., the United States pays rather better wages than private employers, while its professional employees very generally receive much less.

Closely connected with the matter of rates of pay is the matter of title and position. No matter what ability a civilian engineer engaged on river and harbor work may possess; no matter how great a work he may design, his title is that of "Assistant Engineer," and his position is a subordinate one. The public so recognizes it; and until this is remedied, it will be of little use to agitate for an increased rate of payment. Members of Congress will say with truth that $200 to $300 per month is ample compensation for an "Assistant Engineer."

Various plans have been proposed for reorganizing our system of public works with a view to a more equitable treatment of the engineers employed upon them; but the great trouble with most of these plans has been that they involved changes altogether too radical. It has been proposed, for example, to take the control of these works entirely out of the hands of the officers of the Corps of Engineers. We are very sure that a strong protest would go up against any change of this sort, from whatever source it might come.

Among the officers of this corps are some of the ablest and most competent engineers that the country possesses. They are a set of picked men of thorough education and experience, and they have carried out the great works entrusted to their charge, involving the expenditure of hundreds of millions, with a faithful devotion to duty, a strict honesty, and an entire freedom from political intrigues, which are a lasting honor to them and to the profession to which they belong.

It may be said that if the officers of the Engineer Corps are able engineers, what is the need for engineers under them in other than subordinate positions? We will try to make clear why there is such a need. Out of a total number of officers in the Corps of Engineers, there are approximately 5 colonels, 12 lieutenant-colonels, 25 majors and 30 captains, or let us say in round numbers, about 75 men who are of sufficient age and experience to take responsible charge of large works.* The lieutenants and second lieutenants which form the remainder of the corps act as assistants to the officers of higher rank in the corps, instructors at West Point and Willet's Point, and in general occupy such positions as will fit them for places of greater responsibility at a later date. It will, of course, be understood that West Point cannot turn out full-fledged engineers any more than the civilian schools of engineering. In fact, the West Pointer at graduation may be less advanced than his civilian brother; for he has had to spend much of his four years' course on purely military studies.

These 75 men, more or less, have to supervise the expenditure of all the sums appropriated for river and harbor improvements, for the construction and repair of lighthouses, and for fortifications, a total of from $25,000,000 to $40,000,000 per annum. Besides this they have to report on a great variety of projected works, and on obstructions to navigable waters, to serve on boards and commissions, and as delegates to foreign countries,, military attaches, etc., to conduct the municipal engineering work of the city of Washington and supervise its public buildings and parks, and to perform various other incidental duties.

Another fact must be taken into consideration. Not every one of these seventy-five or more officers has sufficient engineering ability to handle efficiently large and difficult engineering problems. They have, it is true, professional training and experience; but in the making of a really great engineer we must always allow Nature some part. If one were to pick from the best civilian engineering schools, 75 students at their graduation, and attempt to make engineers of them all, it would be strange, indeed, if more than 50 per cent. proved to have ability enough to reach a Chief Engineership solely on their own merits. There is no reason why we should expect to find a greater proportion of prizes in selecting engineers from the graduating class at West Point; in fact there may be less reason, for the boy of 16 to 18 who starts for West Point seldom does so with the desire or expectation of becoming an engineer.

As a matter of fact, we find that the officers of the Corps of Engineers vary greatly in their professional ability. Many of them are indeed engineers of the highest rank. On the works carried out under their charge, when the demand on their time permits, they originate the design, take the responsibility of deciding all matters in which technical questions are involved, and are in actual fact the Chief Engineers of the work.

Another class of officers are frankly aware of their inability to handle intricate technical problems. They are the executive heads of the works under their charge; but all matters of a technical or professional character they turn over to their assistants. It must be said, too, that nearly all the officers of the corps are being compelled more and more to follow this course, no matter what their engineering abilities may be, through the multiplicity of the duties heaped upon them. There are, all told, but 24 hours in the day and 365 days in the year; and it needs but an examination of the amount of work which some of the engineer officers have laid upon them to realize that it is a physical impossibility that any one man can perform even a small part of the responsible engineering work which must be done in the course of a year.

The reform that we would advocate, therefore, is merely a frank recognition of the existing state of affairs. An officer in the Corps of Engineers is still the executive head of the works under his charge, and the people want him to continue the executive head; but he is no longer the Chief Engineer, and from the nature of things he seldom can be. The position he occupies and ought to occupy corresponds to that of the Commissioners in charge of large public works of states or cities, or the General Manager of a railway corporation. The laws and the regulations of his corps should be so amended as to recognize this, and also to provide for the employment of actual Chief Engineers on works of importance, exactly as the Commission in charge of building an important bridge, dam or aqueduct selects a Chief Engineer. It goes without saying that such a chief, entrusted with the responsibilities that would naturally attend such a position, would be entitled to a salary proportionate to his responsibilities.

But, it may be said, would not this increase the annual expense to the Government for engineering work? Probably it would, but the trifling amount which would be thus expended, would, we believe, be far more than offset by the saving that would be made in the total cost of the work done.

There are two tasks which ought to be performed by an engineer in the design of any engineering work. One, and the easiest one, is to make the work sound enough and stable enough to meet all demands upon it. Little more is required for this than to follow past precedents. The second and more difficult task is to see how the work can be built or made at the smallest expenditure; and it is here that a wide range of knowledge, inventive genius and familiarity with the latest improvements in materials and processes come chiefly into play.

An engineer who is crowded with work is often obliged to omit the second of these tasks. We doubt not many an officer of the Engineer Corps can call to mind work done under his direction, which he could have carried out at much less expense had he been given time to make all the needful preliminary studies.

We are not arguing, therefore, merely for an increase of salary to a class of engineers who amply deserve it. We are arguing for actual economy in the carrying out of our public works. Let the Government, instead of trying to see how little engineering work it can get along with in carrying out its river and harbor works, empower its engineer officers to employ such engineering talent as the importance of their work justifies, and see that their works are designed for economical as well as stable construction.

A word may now be given to some of the other schemes which have been proposed by those who have sought to benefit the assistant engineers. One proposition has been that the Government should adopt the Continental system of carrying on its public works, should place them under the control of civilians alone, and should create an established corps with life appointments, a regular system of grading and promotion, and pensions after retirement. No such scheme could have the ghost of a chance of adoption in this country. It would not only meet with intense public opposition, but it would make no provision whatever for varying the force to suit the work to be done. There is really no reason why the Government should not do as states, cities and private corporations do; engage professional services when the work in hand requires them, and dispense with them when they are no longer needed.

---

*The new law will increase to nearly 90 the total number of engineer officers of a rank above that of lieutenant; but the law cannot bestow upon the young lieutenants who will be promoted to fill these new positions experience and mature knowledge. That is a matter in which time is an essential factor.

Again, it has been proposed that the Government should simply confine its engineer officers to purely military works and turn over to civil engineers all works of navigation improvement. Every friend of honest government would raise his voice against such a proposition as this. Experience, some of it very recent, has fully shown the danger of making professional appointments dependent on political pulls. The engineer officers now in charge of Government works hold life positions; they are dependent on no party boss for his backing, and their professional honor and integrity is everywhere conceded. To turn over their work to men who would probably depend upon congressional recommendation for their places, would be far from a benefit to the engineering profession.

Some assistant engineers have suggested that their position might be changed to correspond to that of the naval civil engineer corps, and they ask for a similar basis of relative rank, etc.; but they have a mistaken idea of the actual status of that corps. The Civil Engineer Corps of the U. S. Navy now contains only 15 officers, ranking from a Commodore, when Chief of Bureau, down to Lieutenants of the Junior grade. Excepting in numbers and in method of original appointment to the lower grades, this corps holds the same position in the Navy that the Engineer Corps holds in the Army; and, like the Engineer Corps, it also has full authority to temporarily employ civilian engineers when the needs of the service require it, and to discharge them when the demand has passed. It is true, that in the Navy, the original appointments are made from civil life; but their number is limited by law, and the pay is by no means high. They have a permanent position and a relative rank; but to apply the same methods to the admission of the U. S. Assistants into the Engineer Corps of the Army, would simply mean the permanent increase of the number of this corps to unnecessary limits.

We see no chance whatever that any of the three plans we have outlined and criticised can possibly be successful. On the other hand the moderate measure of reform which we have proposed is, we believe, entirely practicable, and might be brought about if the profession at large were to take hold of it. The assistant engineers themselves can do little; for agitation on their part will be set down to mere desire for greater perquisites. The officers of the Corps of Engineers can hardly take a prominent part in such a reform, without transgressing the rules that govern their corps. It rests with the engineering profession at large, through its organized bodies, to take up the matter and urge it to a solution.

A great deal is being said concerning the need for a higher standing for the engineering profession, and various large schemes are being discussed to better it. It seems to us wise to undertake the smaller tasks first. If the engineering profession can bring about a just recognition and compensation for the civilian engineers employed in responsible positions on the Government's great works of river and harbor improvement, it will do a great deal to raise and dignify the standing of the profession in the eyes of the public.

LETTERS TO THE EDITOR.

The Paints on the 155th St. Viaduct, New York City

Sir: I desire to offer some criticisms upon the tests of the paints used upon the 155th St. viaduct, New York, as presented by Mr. Henry B. Seaman, in your issue of July 17.

It is very unfortunate that under "kind of paint" he does not state what each paint is composed of. If he had so stated, one could judge better of the value of the pigment part of the paints.

Acording to the list, Nos. 2, 4, 13 and 14 are practically the same, although they represent the product of different manufacturers, and without doubt each has a different percentage of graphite in the pigment. Any one purchasing graphite paint under such a title does not know how much silica or clay or other things and how little or how much pure graphite there may be in it.

No. 1 does not state whether red or white lead was used, and if the result turns out as suggested in the memorandum marked 1, notwithstanding its large percentage of freedom from rust, it has proven itself to be no good for further protection and should be condemned.

One must not suppose that No. 3 means straight red lead and linseed oil, although that impression will prevail to a great extent. It is doubtful if there is much or any of this pigment in this paint marked "antoxide," which is a trade name of the manufacturer for this particular paint. Absolutely pure red lead and linseed oil makes a better record in such tests.

No. 5, the paint showing the largest percentage, was used with three coats, which gives a decided advantage over a paint which has only two coats used, and probably the proportion of durability would be as 3 to 2. Therefore, No. 12 with two coats only would, it is safe to assume, show up with three coats equally as well as or better than No. 5 "Nobrac" (which is carbon spelled backwards and is a trade name), if placed in the same position where it caught the direct effect of the sulphur fumes from the locomotives.

The result of these tests as they appear in your issue of July 7 will be very misleading to the average reader. In order to make a report complete and valuable, a knowledge of the constituent parts of the paint is essential; and if any salesman or agent or manufacturer refuses to give that when demanded, his paint should not be countenanced for a moment. Respectfully, W. B. Parker.

Chicago, Ill., July 11, 1898.

(Mr. Seaman's report was criticised in some other respects in our issue of July 21.—Ed.)

◆

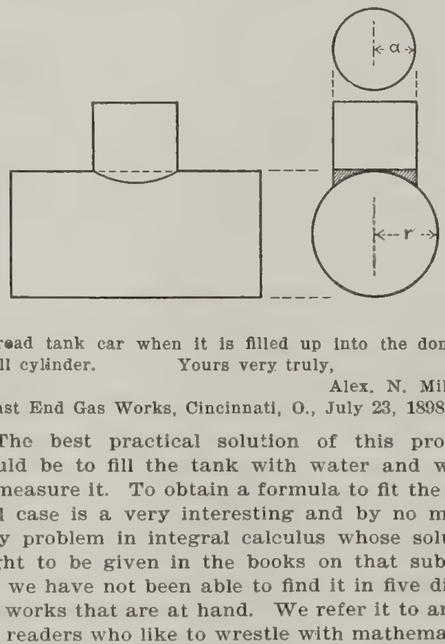
A Problem in Solid Geometry.

Sir: You will favor me greatly by publishing a formula (with its derivation) for the volume included between two cylinders of different diameters whose axes intersect at right angles.

The problem comes up in computing the contents of a railroad tank car when it is filled up into the dome or small cylinder. Yours very truly,

Alex. N. Miller.

East End Gas Works, Cincinnati, O., July 23, 1898.



(The best practical solution of this problem would be to fill the tank with water and weigh or measure it. To obtain a formula to fit the general case is a very interesting and by no means easy problem in integral calculus whose solution ought to be given in the books on that subject; but we have not been able to find it in five different works that are at hand. We refer it to any of our readers who like to wrestle with mathematical puzzles in August.—Ed.)

◆

Power of Windmills.

Sir: There having lately come under my notice, in the Kansas University "Quarterly" for April of last year, an article by Mr. Murphy,* in which he gives the results of a number of tests made by him for the determination of the power developed by wind-engines; and as these tests were carefully made on wheels of a number of different makes and on wheels of different sizes of the same make, all under regular service conditions as they performed their every-day work, and cannot but be of real value, I thought that a comparison of these results of actual practice with the results obtained by the simple little formula which I sent you some two** or three years ago might prove of interest to some of your readers, as it shows that this formula is a sufficient guide for the determination of the size of wheel required for any given amount of work.

The formula which I then proposed was

$$HP. = .0001\ D^3,$$

where HP. is the net horse power developed with an air current of 16 miles per hour, and D is the diameter of the wheel in feet.

From Table I. of the article above referred to, after throwing out the results obtained from the tests on the "Jumbo" and the "Fairbanks" wheels, as these results show only one-tenth the power which wheels of their size should develop, and those of the "Ideal," which are not at all consistent one with another (the 14-ft. wheel giving only about one-third the power of the 12-ft. wheel and one 8-ft. wheel giving three times the power of the other), and arranging the remaining results in the order of the size of the wheels, we form the first four columns of the following table. The fifth column is the average for each size wheel of the values given in the fourth column, and the sixth column gives the horse power for each size wheel as given by the formula $HP. = .0001\ D^3$.

Mill number.	Name of Wind-Engine.	Diam. in ft.	Actual horse power with wind blowing 16 miles per hour.	Aver. horse power of wheels of same diam.	Horse power as given by $HP. = .0001\ D^3$.
9	Aermotor	16	0.433	0.433	0.410
3	Aermotor	12	0.207	....	....
7	Aermotor	12	0.221	....	....
2	Mogul	12	0.260	....	....
13	Aermotor	12	0.171	0.184	0.173
17	Gem	12	0.149	....	....
19	Gem	12	0.162	....	....
21	Halliday	12	0.121	....	....
15	Gem	10	0.082	....	....
16	Halliday	10	0.103	0.093	0.100
5	Aermotor	8	0.072	....	....
6	Gem	8	0.042	0.057	0.051

From this table it will be seen how close the results given by the formula agree with the average results obtained in practice.

In case one is dealing with a strictly high-class wheel, as the Aermoter, it would be better to add another term to the formula, making it

$$HP. = .002\ D + .0001\ D^3.$$

Taking mills Nos. 9, 3, 7, 13 and 5, all Aermoters, from the table above given, we would have:

Diameter of wheel in ft.	Average HP. from tests.	HP. from formula, $HP. = .002\ D + .0001\ D^3$.
16	0.433	0.442
12	0.200	0.197
8	0.072	0.067
or, in round numbers,		
16	0.43	0.44
12	0.20	0.20
8	0.07	0.07

which leaves little to be desired.

Respectfully yours, M. Fargusson.

Southport, N. C., July 22, 1898.

◆

The Moduli of Elasticity of Cast Iron.

Sir: Can you give me, or, if not, where could I obtain, reliable information, based upon tests, by which to determine the modulii of elasticity of average American cast iron for compression and for tension? Many text-books of engineering state that in cast-iron beams under transverse strain, loaded in the usual manner, the neutral axis is situated some distance above the center of gravity of the section, owing to the difference between the compressive and tensile strength of the material; however, they give only one modulus of elasticity. Now, it can easily be proven. theoretically, that the position of the neutral axis is dependent upon the two modulii of elasticity and their difference, and is entirely independent of the ultimate compressive or tensile strength of the material.

Aside from a scientific standpoint, this question may be of interest to engineers, although cast iron is now so little used to resist transverse strain. In many cases, however, reliable formulae for calculating the resistance of irregular cast-iron sections would be useful; e. g., for columns eccentrically loaded, bases, brackets, etc. Similar reasoning is applicable to stone or concrete sections, as, e. g., footings. Very respectfully, F. Carl Pollmar.

Newberry Building, Detroit, Mich., July 19, 1898.

(Wood's "Resistance of Materials" gives a record of a tensile test of American cast iron made by Capt. Rodman, in 1857, which shows that the modulus of elasticity decreased from 27,000,000 at 3,000 lbs. per sq. in. to 18,000,000 at 14,000 lbs., and to 10,000,000 at 24,000 lbs. In Kent's "Mechanical Engineers' Pocket Book," p. 314, there is given the record of another test showing a decrease of the modulus from 25,000,000 at 1,000 lbs. per sq. in. to 12,500,000 at 8,000 lbs., the piece breaking at 23,285 lbs. per sq. in. Wood gives the record of a compression test made by Rodman, of a cylinder 10 ins. long, in which the modulus increased from 11,000,000 to 14,500,000, with an increase of the stress from 1,000 to 15,000 lbs. per sq. in., while a test by Hodgkinson on a bar 10 ft. long showed a decrease in the modulus from 13,000,000 to 11,000,000 for an increase in the stress from 2,000 to 33,000 lbs. per sq. in. The modulus of elasticity of cast iron appears to be extremely irregular, both in tension and in compression, depending, no doubt, upon the quality of the iron, but in tension it always decreases shortly after the beginning of the test, showing no definite elastic limit. Johnson's "Materials of Construction" says the modulus of elasticity in cast iron varies from 10,000,000 to 30,000,000, and that it is approximately the same in tension, in compression, and in cross-bending. Any attempt to construct a formula for strength of cast iron on the basis of its moduli of elasticity in tension and compression, we think, would be a waste of time. Concerning formulas for strength of cast-iron columns and brackets, see Engineering News of Jan. 13 and 20 and June 30, 1898.—Ed.)

---

*Mr. Murphy's experiments were described in our issue of Aug. 19, 1897.—Ed.

**Eng. News, Nov. 14, 1895.

MASSACHUSETTS EXPERIMENTS ON THE PURIFICATION OF FRESH, STALE AND SEPTIC SEWAGE.

By H. W. Clark.[*]

For the past ten years, systematic investigations in regard to methods of sewage purification have been carried on by the State Board of Health, of Massachusetts, at the Lawrence Experiment Station, which was established largely for that purpose. Many of these investigations can be properly classed under the head of experiments upon purification by intermittent filtration, and many modifications of intermittent filtration have been studied. Moreover, all these studies have been carried on, not with the idea of obtaining results only, but of making clear the essential principles by which the purification of sewage can be effected. It seems to be an opportune time to say this, and to present a brief review of a portion of the work of the station during its first eight or nine years of operation, and also of the results of some investigations recently made, on account of the considerable quantity of literature recently published in regard to the results obtained by the so-called septic tank system and bacterial filters of England.

Papers, dealing with the septic tank and bacterial filter methods, have been presented, once or twice recently, to engineering and chemical societies by American engineers and chemists, as something entirely new in sewage purification, apparently overlooking a large amount of data published in the reports of the Board, bearing upon the principles of these methods; that is, the chemical and bacterial actions by which purification is effected by them.

Sewage, as ordinarily understood, is that volume of filth flowing in our sewers, consisting of the wastes from houses, stores and in some cases, streets, together with the water used in washing these wastes into the sewers; sometimes this volume of sewage is largely augmented by the addition of waste liquors from manufacturing industries.

Let us consider, for a moment, the composition of domestic sewage; that is, sewage free or almost free from manufacturing wastes. It is evident that, with a given population, the strength of the sewage produced, or, in other words, the degree of pollution of the water flowing in the sewers varies inversely as the volume of water used by that population. It is generally much more dilute in American than in European cities and towns, owing largely to the extravagant water consumption of the average American municipality. It is a difficult matter to state what is a represenative sewage, but, taking the Massachusetts cities and towns from which the State Board of Health obtains samples of sewage for analysis, the average sewage of these towns and cities analyzes about as follows, in parts per 100,000:

Total solids, 45 parts; loss on ignition, 20 parts; free ammonia, 2 parts; albuminoid ammonia, 0.55 of a part; chlorine, 5.5 parts; oxygen consumed from permanganate, 3 parts.

Of course, during a portion of the 24 hours in almost any of these cities and towns, a sewage is flowing much stronger than that indicated by this average, but in all of them a considerable amount of ground water enters the sewers at all times of the day, and during the night the sewage is much weaker than during the day-time, being in some places largely this ground water.

In 1888 the Lawrence sewage pumped at the Experiment Station contained 1.55 parts of free ammonia, and 0.69 of a part albuminoid ammonia, making its total nitrogen contents 2.4 parts. During 1897, however, the average free ammonia in the sewage pumped was 4 parts, and the average albuminoid ammonia 0.83 of a part, making the total nitrogen contents 4.62 parts; an increase of about 95% in the amount of unoxidized nitrogen present in the sewage. Now, while the strength of the sewage pumped at the Station had doubled, its composition in regard to the arrangement of its nitrogen and carbon contents had also changed very materially; and in regard to this change in composition, which has been many times referred to in the reports, I wish to present a few facts.

It is evident that, when the mixture of water and organic matters of all kinds, such as are found in sewage, has just occurred, and little chance or time has been given for mechanical, chemical and bacterial actions to take place, we must have a liquid flowing in the sewers containing organic matter quite different in its general composition from the same matter in this liquid after opportunity and time have been given for these various actions. The fresh sewage, that is, the sewage just as it enters the sewers from houses or streets, contains free oxygen and generally nitrates and nitrites. As it flows along the sewer, the organic matters are decomposed in the presence of this free oxygen and the oxygen of the nitrates and nitrites, largely by the bacteria present, and the composition of these organic matters is radically altered by these actions, the crude matters being changed to simpler forms, probably in the following way:

The bacteria first attack the carbon, and, in the presence of free oxygen, convert it to carbon dioxide; the nitrogen and hydrogen set free unite to form ammonia, and this joins with the carbon dioxide, forming ammonium carbonate; thus, the free ammonia, so-called, of the sewage increases quite rapidly for a time, while the crude, organic matters decrease. For instance, analyses of samples of sewage from different localities in the State of Massachusetts show the following results upon this point; these analyses having been presented in the reports of the Board for 1894 and 1895:

Samples collected at the Worcester Lunatic Hospital, from the sewer at a point a few hundred feet from the buildings, and a few minutes after the mixture of water and organic bodies has taken place, show only 17% of the total nitrogen of the sewage to be present in the form of free ammonia. Samples from Marlborough, collected at a point, to reach which all the sewage must flow at least four miles, show 56% of the nitrogen present to be in the form of free ammonia. Samples from Framingham, taken at a point, to reach which all the sewage must flow about two miles, show 49% of the nitrogen present to be in the form of free ammonia. Samples taken from a manhole in the Lawrence St. sewer at Lawrence show from 30 to 36% of the nitrogen present in this sewer to be in the form of free ammonia; and samples of practically the same sewage, collected at the Experiment Station, after it had been 24 hours longer on its journey from a point near this manhole through the pipe to the Station, show about 60% of the nitrogen present to be in the form of free ammonia. Reversing these figures, it will be seen that the fresh sewage, taken directly from the Lawrence St. sewer, has about 60% of its nitrogen present in the form of crude organic nitrogen; while the stale sewage, collected at the Experiment Station, has on an average about 40% of its total nitrogen in the organic form.

Investigations in regard to this change have been made at the Station, and published in the reports of the State Board of Health from time to time. For example, upon p. 461 of the report for 1894, the following experiment is given:

A gallon bottle was filled with fresh sewage taken directly from the manhole in the Lawrence St. sewer previously mentioned, and analyzed as soon as possible after collection. Subsequent analyses were made every two or three hours during the first two days of the bottle's standing in the laboratory, and once a day thereafter for a period of six days. The results showed that, upon standing 24 hours, the free ammonia increased about 100%, and the dissolved oxygen and nitrates and nitrites disappeared; the dissolved oxygen being present at the time of collection in an amount equal to about 57% of that necessary for saturation of water at the temperature of this sample of sewage when collected. The total organic nitrogen decreased 50% within 24 hours, and 67% during the entire experiment. The insoluble organic nitrogen decreased about 60% during the first 24 hours, and 80% during the entire experiment. The amount of oxygen consumed from permanganate decreased 50% during the entire experiment, caused by the formation of carbon dioxide. This bottle of sewage stood upon the table in the laboratory, and so was exposed to light, and frequent removal of the stopper allowed the access of air; therefore, it was not under the same conditions as the sewage held in the septic tank at Exeter, England. On the other hand, the bottle was shaken each time before a sample was taken from it for analysis, thus getting an amount of sludge proportionate to the volume of sewage taken for analysis; whereas, the sewage from the septic tank is drawn from a point midway on this tank, and only a small amount of sludge is obtained with a sample of the tank effluent. This experiment and its results were spoken of in the report for 1894, as an illustration of the initial step in the purification of organic matter by bacterial action.

In a discussion of the composition of sewage and the permanency of filters in the report of the Board for 1895, it was stated that, if the sewage is stale when reaching the place of disposal, the organic matter in suspension is finely divided by the comparatively long continued mechanical, chemical and bacterial actions through which it has passed, and a much larger percentage of the organic matter will readily pass into the interstices of the filtering material than will be the case with fresh sewage, and that the surface of filters will not become clogged by the crude organic matters of the sewage so readily as they will when fresh sewage is being applied. Also, it was stated that the organic matter in the stale sewage has apparently been worked over to such an extent during its slow passage through the pipe from the sewer to the Station, that not only has it lost a certain proportion of its sludge, but the remainder is of a nature more easily attacked by the bacteria in the filter than is the fresh organic matter. These statements and the investigations giving rise to them were made because it was evident that the experimental filters in operation at the Station, while receiving with the sewage applied to them a greater amount of organic matter than during earlier years, were producing better results than was the case two or three years previous to this, and also were not storing much of the matter applied.

To demonstrate further the better work of a filter receiving stale sewage than one receiving fresh sewage, an experiment was made in 1896, and published in the report of the Board for that year; two small filters being started, one receiving the stale sewage pumped at the Station, and the other, fresh sewage collected from a manhole in the Lawrence Street sewer. The total nitrogen in the fresh sewage was 4.35, and in the stale sewage, 4.23 parts per 100,000. Only 27% of the nitrogen in the stale sewage was organic nitrogen, the rest being in the form of free ammonia, while the fresh sewage contained 60% of its total nitrogen contents in the organic form, the remainder, or 40%, being in the form of free ammonia. The oxygen consumed from permanganate by the fresh sewage was about 2½ times that consumed by the stale sewage. After six months' operation of these filters, the one which received the fresh sewage had stored 26% of the applied nitrogen, while the one receiving stale sewage had stored but 12%, this latter filter being operated without disturbance of its surface, while, owing to the crude sludge applied with the fresh sewage, the surface of the filter receiving it had to be raked several times during the period of operation.

---

[*] Chemist of the State Board of Health of Massachusetts, Department of Water Supply and Sewerage, Lawrence, Mass.

On account of these and other investigations at the Station, we have long known that the volume of sewage which a given area of filter bed will successfully care for and render pure varies not only according to the strength of the sewage applied, but also according to the composition of the sewage, as I have explained it; that is, the arrangement of its carbon and nitrogen contents, whether in the soluble or insoluble form. Such sewage as that collected from the sewer of the Worcester State Lunatic Hospital contains comparatively little organic matter in solution, and the organic matter in suspension is not finely divided; it is, therefore, evident that when such sewage is applied to a filter, there will be strained out and left upon the surface of this filter a large amount of crude organic matter to be slowly acted upon by the air and bacteria; that is, if the sewage runs directly to this area. If, however, it passes through properly arranged screens and sedimentation basins, a large proportion of this crude insoluble matter can be removed from it before it passes to this filter. Then we have to purify by filtration a body of liquid containing perhaps only a small proportion of its original organic pollution; but we shall also have a large body of sludge, so-called, to be in some way disposed of.

On the other hand, a sewage similar to that now and for several years past pumped at the Lawrence Experiment Station, or pumped to the beds at Marlborough, can be called in distinction from the fresh Asylum sewage, a stale sewage; that is, one in which the crude organic matter has been worked over by chemical and bacterial actions, resulting not only in a change of the form in which this matter is present, but also in the loss of a portion of the primary amount, this loss occurring as has been explained.

To purify sewage, we separate from a large volume of liquid the relatively small amounts of organic and mineral matters contained in this liquid.

Intermittent filtration is a bacterial and oxidizing process of purification by means of which the organic matter present in the sewage is removed, both by change into gaseous forms and escape into the air, and change to the inorganic form, and passing away as harmless mineral salts in solution in the effluent of the filter. We have seen how the organic matter, by a process of decomposition, that is, by the action of a certain class of bacteria working in the presence of oxygen, is gradually changed to free ammonia. It is this free ammonia that the nitrifying and oxidizing bacteria present in the filter change to nitric acid, which joins with some such base as potassium or sodium present in the sewage, to form nitrates which, as stated, come through in solution in the effluent. This action is the main one upon which the purification of sewage by intermittent filtration depends, and all care of an intermittent filter is a constant aim to so handle it that everything will be favorable for this action to take place and continue vigorous.

We have seen the different form in which the carbon and nitrogen present in the sewage may reach the filter's surface, according as the sewage to be disposed of is fresh or stale, and it is evident that the amount of work to be done in the filters by the bacteria present varies greatly, owing to this fact. That is, if the sewage is as fresh as the Worcester Asylum sewage, a much larger amount of work and a greater change in organic matter has to be accomplished in the filter before the sewage is purified than has to be done if stale sewage, which has been long enough in the sewer for the beginning of the bacterial actions to take place, is applied to the filter.

The question now being agitated is whether the breaking up of the organic matters cannot be better effected by holding the sewage in a tank without access of air, and thus aid the growth of that class of bacteria which can live without air, than with free access of air and action on the filter's surface, and within the filter by the bacteria acting in the presence of air.

I will present here a few examples of what can be accomplished by the filtration of sewage without preliminary forced putrefaction. For periods varying from eight to ten years, we have had in operation at the Station seven large experimental filters, 1-200 of an acre in area, and containing sands or gravelly soils common to New England. These filters have been operated at rates of from 20,000 to 120,000 gallons per acre daily, and daily analyses made of the sewage applied to the filters and the effluents from them. We have also kept watch of the condition of the filtering material, in order to learn definite facts in regard to the storage of organic matter in this material, as the maintenance of an equilibrium between the organic matter applied to the filter and that lost by being nitrified and changed to the inorganic form, or passing away into air in the form of carbon or nitrogen gases, is necessary, in order to insure the permanency of a filter; that is, the permanency of the whole depth of the filter body, not making allowance for any removal of clogged sand from the filter's surface.

It is a fact that there was, for some years after the filters were started, an increasing accumulation of sludge or organic matter stored in these filters. The reason for this is not, perhaps, entirely clear. Fresh sewage, so-called, was being applied during the first years of operation, instead of the stale sewage subsequently applied; but the stale sewage contains more sludge than the fresh sewage did, owing to the increased strength of all the sewage flowing in the sewer and pumped to the Station. On the other hand, we have taken better care of the upper portion of each filter bed for the past five or six years; that is, the surface of each filter has, during these years, been disturbed by occasional raking, and has been spaded over to a depth of 6 ins. each spring and fall. One of the filters, however, when clogging began, had been treated in this way with apparently little effect in aiding the removal of the stored organic matter, or in producing better filtration results.

It seems probable, taking everything into consideration, that, besides the improvement of all the filters of late years, caused by increased care of the upper portion of them, the stored organic matter was, during the clogging period, being slowly worked over by the millions of bacteria present, until, finally, small portions of it arrived at a condition in which it was easily attacked by the nitrifying and other bacteria present in the filter, and with the usual results. When this time was reached, each daily addition of indigestible matter, which had to remain in the filter and be worked over for a long period, was offset by the daily amount which had been worked over for this long period and was being removed as nitrates in the effluent.

Analyses of the sand during this period of clogging showed the presence of a large amount of fatty matters. Now, however, although the sewage applied contains fully as much fat as was present during the first years of operation, it does not seem to accumulate in the filters. Whether we have cultivated in the filters a species of bacteria now capable of disposing of this fat readily, or whether the more prolonged actions of the bacteria in the sewer and sewer pipes, caused by the longer stay of the sewage in these places, have broken the fats and fatty matters into simpler forms, more easily handled by the bacteria present in the filter, we cannot state. The latter theory seems the more probable one.

It is worth mentioning here that we have in one of the towns of the state two experimental filters in operation, receiving tannery sewage containing a very large amount of fat. Tannery sewage is, of course, of considerable age and in an advanced state of putrefaction when allowed to run to waste from the tannery, and the fatty matters present do not clog the filters, but pass through into the effluent.

Quoting from our reports, I have given experiments showing the change in the composition of sewage with increased age; showing also the loss of crude organic matter taking place as sewage grows older; and showing the greater ease with which intermittent sand filters can dispose of stale sewage than fresh sewage. These facts are now being taken advantage of by the so-called septic tank system, first in operation in Exeter, England. This is an air-tight tank into which the sewage passes, and is retained for a time in order to allow the bacteria of decomposition and putrefaction to break up the organic matters into simpler forms, and thus reduce the insoluble matter, or sludge, by causing a considerable portion of the carbon and nitrogen to be so changed that it is either in solution in the sewage, or will pass away from it in the form of gas. As I have said, I have given data showing that the actions by which this process is made successful have been thoroughly understood by us for a considerable time, and the fact that sewage would lose a certain percentage of crude organic matter when held in a body has certainly been known. Anyone who has ever had any experience with, or noted the changes taking place in an ordinary cesspool, must have had their attention drawn to this fact. We had not, however, ever considered that these actions could be utilized as now proposed by the septic tank system.

We have, however, studied the method to some extent during the past few months with very interesting results. The sewage remains in our tank 24 to 36 hours, and is drawn from a faucet midway between the top and bottom of the side of the tank, as at Exeter. Thus we avoid drawing out the sediment from the bottom of the tank, and the fat and fatty matters which accumulate upon the surface of the sewage. The sewage, after its stay in the tank, is, when drawn from it, of an exceedingly offensive odor, quite highly colored, but clear for sewage, and containing a relatively small amount of matters in suspension. The free ammonia has increased slightly, and the total albuminoid ammonia has decreased about 50%, and the organic matters indicated by the determination of oxygen consumed from permanganate also about 50 per cent. Of course, no nitrification takes place within the tank, and we have found that all the nitrifying and oxidizing bacteria, that is, those bacteria depending upon the presence of oxygen for their life and functional activities, are destroyed while the sewage is passing through the tank. When entering, the sewage contains nearly 4,000,000 bacteria per cu. cm., and when drawn out about 250,000 bacteria per cu. cm., a reduction of 95%.

The following analyses show (1) the composition of the fresh sewage taken from the manhole at the Lawrence St. sewer; (2) the composition of the stale sewage as it is pumped at the Station, which enters the septic tank; and (3) the composition of the sewage drawn from this septic tank:

(Parts per 100,000.)

	Ammonia		Nitrogenas		Oxygen consumed.	Bacteria, per cu. cm.
	Free.	Alb.	Nitrates.	Nitrites.		
From sewer	2.60	1,18	0.10	0.0210	8.50	1,950,000
Station sewage..	4.50	1.05	0.00	0.0000	4.80	3,800,000
Septic sewage ..	5.50	0.55	0.00	0.0000	2.50	250,0 0

We see by the three analyses the following changes: A regular decrease in the albuminoid ammonia, with the necessary increase in the free ammonia resulting from this, and a regular decrease in the amount of oxygen consumed from permanganate. The sewage taken from the manhole at the sewer has little odor, and that not at all offensive. As pumped at the Station, the odor is only slightly increased; but as drawn from the septic tank, the odor is very offensive; that is to say, we have had changes, produced by the bacteria working upon the organic matter present, something as follows:

These organic bodies are compounds of carbon, hydrogen, nitrogen and oxygen. The first action is the formation of carbon dioxide, free ammonia —which joins with this carbon dioxide—water, and probably nitrous oxide. The next action which takes place in the septic tank is the further breaking up of these bodies, without the presence of free oxygen, and the formation of ill-smelling gases; that is, the organic matter has been well broken up and is well on the way to its reduction—if I may call it so—to its lowest terms by the bacteria acting during the time in which the sewage has been held in a body.

The septic sewage is applied to two filters, one an ordinary intermittent filter containing 5 ft. in depth of sand of an effective size of 0.23 mm., a sand very favorable for effective and satisfactory purification by intermittent filtration. The rate of operation of this first filter up to the present time has been 100,000 gallons per acre daily. Nitrification was very slow in starting in this filter, much slower than would have been the case with a filter receiving sewage in a less advanced state of putrefaction, and containing the large number of bacteria present in the sewage as it is pumped to the Station, and before entering the septic tank. Even at the present time, after four months' operation, although nitrification is quite active within this filter, averaging about 2½ parts nitrates in the effluent during the past few weeks, still the effluent is very turbid and ill-smelling. If the ordinary sewage pumped at the Station had been applied at an equal rate during these four months of operation, we should certainly be obtaining an effluent at the present time, clear, practically colorless, with little turbidity and no odor.

The reason for the comparatively poor result obtained so far by the intermittent filtration of this septic sewage is undoubtedly due to a number of facts, the principal one being that, although the nitrifying bacteria have finally become established within the filter, yet each application of sewage, passing down through the filter, has set free from it the gases generated in the septic tank and retained in solution in the sewage until this time, these gases being inimical to the life of the bacteria in the filter, which are of an entirely different class from those growing in the septic tank. The gases also rapidly exhaust the air in the filter; the filter effluent containing no dissolved oxygen in distinction from the effluent from filters receiving ordinary sewage. It can be said also that, while the filter shows no signs of clogging, and the sewage disappears quite readily from its surface, still the turbidity and disagreeable odor of the effluent seem to be increasing at the present time, rather than decreasing.

The second filter receiving this septic sewage is a bacterial filter, so-called, containing 5 ft. in depth of small pieces of coke. Before describing the action of this filter, I wish to make a few statements in regard to bacterial filters. Of course, all properly constructed filters are bacterial filters. Lately, however, this name has been given to a class constructed and operated in a somewhat novel way. The first bacterial filter in operation at Lawrence was started early in 1894, and contained 5 ft. in depth of gravel. Since then, others have been started, of cinders, coke, etc. The method of operation and the reason for naming them as they have been is as follows:

They are all filters of comparatively coarse material, having a large percentage of open space, and the sewage is applied in such quantity that this entire open space is filled daily, or even several times daily, the idea being that, as the sewage is drawn off, this open space becomes filled again with air, and hence the organisms work through the entire depth of the filter, instead of working in the upper layers only.

A bacterial filter receiving septic sewage was put in operation nearly four months ago at a rate of 800,000 gallons per acre daily. At this rate the sewage passing through it has had removed from it a very large percentage of its organic matter. No nitrifaction, however, has started within this filter, and reasoning from previous results it would seem probable that a considerable percentage of the organic matter removed from the sewage by the filter is being stored within it at the present time. I say, this seems probable, reasoning from results obtained with fresher sewage. It may not be so, however. We have found that in intermittent filtration fully 30%, on an average, of the nitrogen in the applied sewage escapes into the air in the gaseous form, and it is very possible that a much greater percentage is lost in this manner from the bacterial filter receiving septic sewage with its organic matter well on the way towards its reduction to its lowest terms, as has been explained.

We have, moreover, in this filter evidently a class of bacteria which carry on the purifying action begun in the septic tank still further, even although the nitrifying organism is not present, and as a result the effluent of the filter, although containing a large amount of free ammonia and an amount of albuminoid ammonia considerably above the average amount usually present in the effluents of our intermittent filters receiving ordinary sewage, is odorless and remains so indefinitely, and is only slightly turbid: That is, the ill-smelling hydrogen gases have either been destroyed or have passed away from the sewage during its stay in the filter, and the organic matter remaining in the effluent has apparently reached a state where no further putrefying actions can take place. This effluent is of a very good appearance as far as color and turbidity are concerned, being much better in this respect than the effluent of the intermittent sand filter receiving septic sewage and operating at only one-eighth the rate of this bacterial filter. Analyses of these effluents are as follows:

(Parts per 100,000.)

	Ammonia.		Nitrates.	Nitrites.	Oxygen consumed.	Bacteria, per cu. cm.
	Free.	Alb.				
Effluent of bacterial filter …	4.30	0.17	0.00	0.0025	0.75	55,000
Effluent of intermittent filter…	1.75	0.13	2.60	0.2600	1.08	140,000

The aerated gravel filters described in our Reports also gave an end result in regard to producing an odorless effluent similar to this. On p. 469 of the report of 1895, the following statement was made:

> Comparing the resulting liquids after the treatment of sewage by various methods of removing sludge, it is noticeable that the organic matter in the liquids, after rapid filtration combined with aeration, is of a different character from the organic matter in the sewage resulting from the other sludge removing processes; that is to say, even when the organic matter as shown by the albuminoid ammonia is present in these effluents in as great quantities as in sewage after chemical precipitation or straining through coke, it has passed through such chemical and biological changes that it develops offensive odors very slowly on standing.

Bacterial investigations are, of course, being made, and the organisms so far isolated from the effluent of the septic tank show greater development at a temperature of 65° F. than at either a lower or a higher temperature.

In conclusion, it can be said that the septic tank process is one of much interest to anyone studying sewage purification, but there are two drawbacks: First, the fact that a large body of septic sewage must be exceedingly offensive and cause a nuisance where the same volume of fresher sewage would not cause a nuisance; and second, the construction of a reservoir of sufficient storage capacity to hold a large volume of sewage—that is, one day's flow from a municipality of average size—would be quite an expense. It seems probable to me, however, that a much smaller tank can be used in proportion to the volume of sewage flowing than is used at Exeter, and for this reason: A sewage of ordinary age, that is, one which has traveled for any great distance in the sewers, will, when it reaches its point of disposal, be practically free from dissolved oxygen, all having been used up by the bacteria and organic matter before reaching this point. Now, if such sewage runs into a properly built septic tank, no air will be carried in with it, and the length of time which it remains within the tank need be only long enough to allow a complete precipitation of the insoluble matters, and the accumulation, to some extent, of the fats upon the surface of the sewage. These matters can remain in the tank for an indefinite time; and, being acted upon by the bacteria of decomposition and putrefaction, will be slowly changed to the soluble form, and pass away to a large extent, perhaps, in the effluent of the tank. Thus, the sludge, the difficult factor in sewage purification, may perhaps be disposed of, and the sewage, staying a shorter time within the tank, will not have such an offensive odor, and will not make the disposal area so great a nuisance. The process has not been on trial long enough as yet, however, to determine accurately what percentage of the total volume of sludge can be gotten rid of in this way.

A COMPARISON OF BRITISH AND AMERICAN NAVAL VESSELS.

The following comparison by an English naval expert of the vessels, guns and armor in the British and United States navies, we find in the New York "Tribune," credited to the London "Mail." It appears to be a very fair and unprejudiced statement, and is, so far as we are aware, in accordance with the actual facts. The British navy is certainly in advance of all others in the world in its use of the wire-wound gun, which, by permitting higher pressures, larger powder charges and longer barrels, sends its projectiles home with a force which ordinary built-up guns of the same caliber cannot equal. The critic's remarks respecting the speed of battleships are also noteworthy:

American guns are not, I take it, so good as ours. The 60-ton weapon is a fine and powerful gun and has stood the strain of prolonged firing, but it is not better than the British 67-ton gun and is inferior, both in rapidity of fire and penetration through armor, to our 46-ton wire weapon. There can be little doubt that our 6-in. and 4.7-in. weapons of the quick-fire type are ahead of anything now manufactured in the United States. The British-built "New Orleans" is pronounced by American naval officers in the West Indies the best cruiser of her size in the United States Navy. Her guns have excited particular admiration, owing to their simplicity, accuracy and rapidity of fire.

When we turn from guns to projectiles and armor we are upon less certain ground. Two years ago the American Carpenter and Wheeler-Sterling shells were better than anything made in England. It is possible that to-day they are ahead of our projectiles, though with the very great attention given to this point by British manufacturers recently, it is not altogether likely. Our Hadfield projectiles are, I believe, among the very best. Still, the American Navy is probably at this present minute supplied with better armor-piercing projectiles than the British Navy, for the reason that the United States did undoubtedly get ahead of us.

In the matter of armor-plates England fell behind because, for some reason or other, the Admiralty in our earlier Harveyized plates did not use nickel. The Americans adopted a nickel steel, which has performed wonderfully in trials. But here again, I am glad to say, we have advanced greatly. The Krupp gas-hardening process, which has been adopted by our three great armor-making firms, when applied to nickel-steel plates, such as we now use, gives splendid results. The firm of Vickers has particularly distinguished itself for the armor which it has turned out in the last few months. Nor are Brown and Cammell behind their enterprising rivals.

The point in which American ships excel ours is in battery. It is well known that, ton for ton, the United States warship is beaten in armament only by the new ships now constructing for Germany, a young and audacious Power. Taking two new ships, British and American, these are the armaments:

"Canopus" (British).	"Alabama" (American).
Four 12-in.	Four 13-in.
Twelve 6-in.	Fourteen 6-in.
Ten 12-pdrs.	Seventeen 6-pdrs.
Six 3-pdrs.	Six 1-pdr.
Eight Maxims.	Four Maxims.
Four torpedo tubes.	Four torpedo tubes.

The American ship has a much heavier battery. Though, as has been said above, the British 12-in. gun shoots harder than the American 13-in., the projectile of the American gun is 400 lbs. heavier than that of our gun. Probably with crews of equal efficiency the American ship would win on guns alone, if her weapons were of the most recent type. She has two more 6-in. quick-firers, and the 6-in. gun is a very formidable and useful weapon.

In the matter of ammunition the British ship is better supplied for her heavy guns. She is no better supplied with 6-in. shells. And it must be remembered that she is 1,400 tons larger.

In armor the difference is most striking. These are the facts, set forth side by side to afford a contrast:

British.	American.
Side—Belt, 250 ft. by 18 ft. and 6 ins. thick.	Belt, 220 ft. by 7½ ft., from 16½ to 9½ ins. thick. Above this a belt 140 ft. long by 8 ft. broad, 5½ ins. thick. Above this another tier of armor, 140 ft. long by 7 ft. 6 ins. broad, 5½ ins. thick.
Heavy guns — Barbettes, 10-in.; shields, 6-in., sloped.	Barbettes and turrets, 15 to 17 ins.
6-in. guns — 6-in. casemates.	5½ ins.
Protective deck—Two, one 1-in., the other 2½-in.	One, 2¾ to 4 ins.
Armor on ram — 2 ins., a broad belt, covering the ship forward.	4 ins., a narrow belt.

It will be seen that the American ship is, beyond question, better protected than the British vessel. In the American the armor virtually sheathes the whole vessel amidships. In the British ship the armor is only a patch

—though a large patch. Moreover, there is no thick armor on the water-line, as we find in the American.

In speed and coal supply the British "Canopus" has a great advantage. Our ship is nominally good for 18¾ knots, and carries 1,900 tons of coal. The American is 2¾ knots slower, and carries 1,200 tons of coal. In practice the difference of speed should be about two knots. Great importance is attached in this country to speed, and very rightly. We must always force the fighting if war comes, and our ships must be able to catch their enemies. They are none too fast, as matters stand, for France has smaller-battle ships than the "Canopus," now nearly ready for sea, with engines as powerful as hers.

It would be wise from our point of view to class the "Canopuses" as armored cruisers of the finest type. Then, perhaps, we should hear less of the superiority, in actual fighting points, of such ships as the "Alabama."

Turning to our cruisers, it does appear that the Americans are ahead of us. The "Brooklyn," for example, is much more heavily armed than the "Powerful" of about her own date; is very nearly as fast, and in coal endurance is equal to the British. Our smaller cruisers are enormously below the Americans of their own size in armament. I have always held with our American friend that in war the object should be to kill your enemy as quickly as possible, before he kills you. The more guns you can carry the more likely you are to hit the enemy and to kill his men.

It is said: "Oh, but we carry so much more amunition." No doubt we do, but the question is this, Would it not be wiser to copy other Powers, and translate this ammunition into guns? I notice that the newest Russian cruisers, of the size of our "Hermes," carry one more 6-in. gun, and have 180 rounds of ammunition per gun, against our ship's 200. Yet the Russian ship will steam 23 knots, natural draught, and ours only 20½.

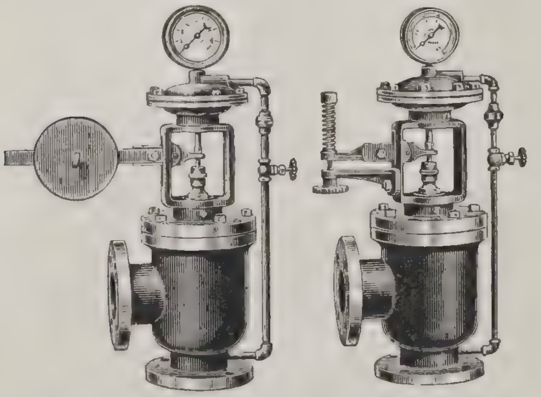
Take the "Olympia" as another example. She is just about the size of our "Eclipse." But she is 1½ knots faster; carries 300 tons more coal; has 4-in. armor on her big guns; a deck much thicker than the "Eclipse's," and a battery out of all proportion more powerful. Here are the figures:

Eclipse."	"Olympia."
Five 6-in. quick-firers.	Four 8-in.
Six 4.7 in. quick-firers.	Ten 5-in. quick-firers.
Eight 12-pdrs.	Fourteen 6-pdrs.
Eleven small.	Ten small.
Three torpedo tubes.	Six torpedo tubes.

Summing up, then, we may pronounce our battleships in important respects better than the American, our guns much better, our projectiles as good, our armor as good, and our cruisers much worse.

NEW STYLES OF REDUCING VALVE.

The accompanying cuts show two styles of reducing valves recently put on the market by the Fisher Governor Co., of Marshalltown, Iowa, who are also manufacturers of the well-known Fisher steam pump governor. A standard gage is furnished with each valve, so that the low pressure can always be seen. The one with weight and lever is especially adapted for extremely low pressures, and it will hold the lower pressure uniform even when the boiler pressure increases, or a greater part of the radiation is cut off. The style with spring attachment is more especially adapted for steamboat work. The valve and seats of these reducing valves are made of phosphor bronze.



New Styles of Reducing Valves.
Manufactured by the Fisher Governor Co., Marshalltown, Iowa.

ELECTRIC WELDING OF STREET RAILWAY RAILS.

In June, 1893, the Johnson Company, of Johnstown, Pa., which had been for nearly a year previously experimenting with the electric welding of rails, began welding the rails of the West End Street Railway of Boston, Mass. The apparent success then attained encouraged other roads to try the new method, and in a short time about 50 miles of track had been welded by this method in Boston, Cleveland, Johnstown, Brooklyn, St. Louis, and Detroit.

The approach of winter and with it cold weather caused the rail to contract and resulted in the breaking of many of the joints, usually just to one side of the weld showing that the breaks were the result of a weakening of the steel consequent upon the intense heat produced by the electric current. The experiments conducted at that time determined quite conclusively that a strength of 100,000 lbs. for a 6-in, rail, or thereabouts, was ample to resist the tension resulting from the annual change of temperature. 200,000 lbs. was therefore assumed as a necessary joint strength. A series of tests made on short sections demonstrated that welded joints could be made capable of standing considerably more than this figure. As a result of the failure of electric welding in Boston and elsewhere, the Johnson Co. refrained from a general introduction of its system and began a series of careful experiments to see if it were possible to produce the weld with its desirable features and still not destroy the structure of the adjacent steel. The solution was found to be very simple, and consists in putting the material at the weld under great pressure just after the weld is made and the current cut off and holding this pressure while the steel cools. In this way, the steel is prevented from crystalizing and losing its elasticity at the point next the weld. The company, after further experiments to thoroughly test this discovery, is again in the market.

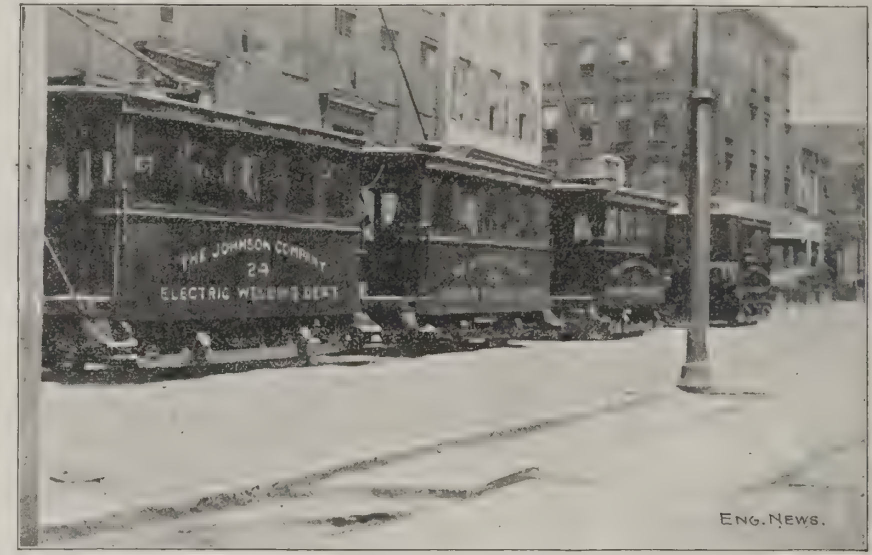


FIG. 1.—THE ELECTRIC RAIL WELDING EQUIPMENT OF THE JOHNSON CO., JOHNSTOWN, PA., NOW OPERATING IN BROOKLYN, N. Y.

At present one of its equipments is in Brooklyn, engaged in welding about 45,000 ft. of double track on the Nassau Electric R. R. The welding equipment is composed of four cars, as shown in Fig. 1, containing the various electrical machinery instruments, sand blast, water tanks, regulators, etc. This train is transported about the country on flat cars, which land it as near the point where work is to be done as possible. The cars are then run onto the street railway lines and as each car is equipped with its own trolley and motors they are propelled by their own power to the desired position.

The car to the left in Fig. 1, contains a booster built by the Crocker-Wheeler Electric Co., of Ampere, N. J. This car complete weighs 28,000 lbs. The booster is a 125-HP. 500-volt, 200-ampere direct current electric motor directly connected to a 70-K-W. dynamo wound for 420 amperes at 175 volts at a speed of 750 revolutions per minute. Current for operating the booster motor is taken from the trolley wire by an ordinary trolley pole on top of the car and the altered current is carried through flexible cables to the next car where the rotary converter is placed.

In the converter car are the instruments for indicating line and booster voltage and currents in the various circuits as well as resistances for regulating the output. The rotary converter is a 4-pole machine, built by the Thomson Electric Welding Co., of Lynn, Mass. This machine has one armature provided with a commutator on one end and collector rings at the other. It runs 500 revolutions per minute, taking current on the direct current side from the booster circuit and converting it into alternating current at 300 volts. The alternating current is taken from two collector rings and passes by flexible cables to the next car, in which is found the main switch, the relative coil for current regulation, the massive welding transformer and clamp and the mechanism for moving this. Here also are the pumps, tanks, etc., necessary for cooling the jaws of the clamp.

The welder is nothing more nor less than a large transformer, mounted upon a bail which swings from a heavy arm or crane arranged to be raised or lowered or swung from side to side by means of screws driven by a small electric motor taking current from the trolley. The transformer core is laminated soft iron wound with two primary coils for 300 volts alternating current and about 260 amperes, and insulated with oil. The secondary consists of one turn, which is only completed when welding, furnishes from 30,000 to 50,000 amperes at from 2 to 4 volts. This secondary is made up of the two casings or cast metal jackets, which surround the primary coils. The contact blocks forming the jaws of the welder are

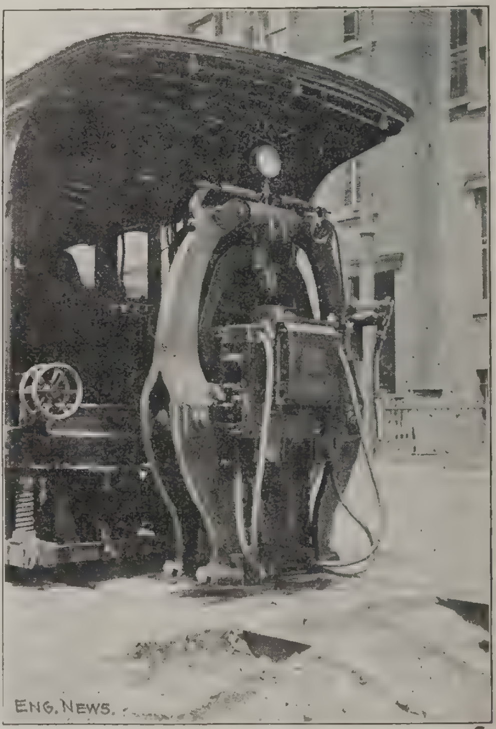

Fig. 2.—The Thomson Electric Rail-Welder.
Thomson Electric Welding Co., Lynn, Mass., Makers.

hollow and are connected with a small pump which keeps water circulating through the blocks close to the weld and thus prevents their overheating. To obviate carrying a large quantity of water it is cooled by a form of air cooler placed on top of the car, seen in Fig. 1. This is a shallow round galvanized iron tank provided with two bottoms, between which is arranged a spiral strip forming a winding passage at the center of which air is admitted from a small rotary blower. The upper bottom is full of fine holes, and the water above this is prevented from leaking through by the air which forces its way up through the holes, producing a cooling of about 10 or 20° F., as it passes out through the water.

The amount of current applied at the weld is regulated in two ways; directly, by adjusting the pressure of the jaws; indirectly, by varying the field resistance of the booster. A reactive coil is also placed in series with the primary of the welding transformer. This, however, is only used to prevent excessive sparking at the switch terminals when the circuit is broken. It consists of a simple solenoid in which is suspended a core composed of a bundle of soft iron wire.

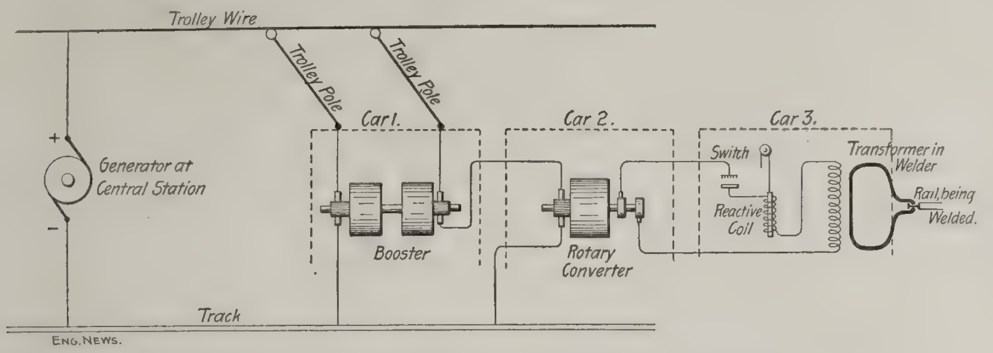

FIG. 3.—DIAGRAM OF CONNECTIONS AND APPARATUS EMPLOYED FOR ELECTRIC RAIL-WELDING.

The manner of applying the clamping to the rails is quite clearly shown in Fig. 2, in which it will be noticed that two heavy steel levers are pivoted beyond their centers and are connected at their upper ends by a double-acting hydraulic jack. A small hand pump, mounted upon one of the levers, suffices to produce any desired pressure in the jack which is referred through the levers to the joint.

Farther forward, in Fig. 1, and always in advance of the welding train just described, is the sand blast car containing a sand blast outfit, made by B. C. and R. A. Tilghmann, 126 S. 11th St., Philadelphia, Pa., an emery wheel, electric heaters to dry the sand, an electric motor and a belted air compressor. This car is cut away at the rear and is provided with canvas curtains which permit the joints to be cleaned previous to welding without scattering the sand and annoying passers by. The operator wears a helmet and cape, covering his head and shoulders.

In operation, the cars are run out at night, so as to interfere as little as possible with the schedule, and the sand blast is put to work clearing the rail joints already exposed by removing the paving for a space of about 2 × 2 ft. Shims of sawed rail sections are next wedged into place between the ends of the rails. The welding train is then moved forward until the welder hangs over the center of the joint. Two steel splice bars, 1 × 3 ins. by about 19 ins. (Fig. 4), are next clamped into place, so that the central strip (a) of each bar covers the junction of the rails. The pressure on the jaws is run up to 7-10 ton, or about 1,400 lbs., by the hand pump, current is turned on and the metal is watched until it welds. The current is broken and the pressure is increased to about 35 tons, under which the joint is kept until it is cooled. The jaws are then loosened and the car moved back just enough to put the jaws over the portion (b) at one end. This kite-shaped raised portion is produced by stamping the bars at the factory, so that a depression is formed on one side and the projection on the other. Into the depression on the back is fitted a flat steel stamping. Its purpose is to ensure an even bearing of the clamp blocks. The second weld is next made and cooled under pressure as before, and then the weld on the opposite end of the splice bar. At the end of about 15 minutes (during which current was on for about 6 minutes) the rail joint is complete and ready for use.

The amount of excavation required at the joint is small, considerably less than with the various forms of so-called cast welds. It is claimed that joints made by the welding process meet all the requirements of strength, give a certain amount of flexibility, an amount about equal to that of the rail itself, and afford an electrical bond far superior to any other form of joint.

Regarding the cost, an approximate idea can be obtained by figuring backward. There are three welds, per joint, current being on about 2 minutes per weld, a total of 6 minutes, during which close to 100 K-W. will be necessary to operate the welder and various auxiliary apparatus. This is 1-10 of 100 K-W. hours, or 10 K-W. hours per joint. The dollars and cents of this will depend upon the particular road where the welding is in progress, being more or less according to local circumstances and the efficiency of the plant. In any case, five or six men are necessary to operate the train as described and this force will average about 18 or 20 joints in 7 hours or between 2½ and 3 joints per working hour. With 30-ft. rails double track there would be about 700 joints per mile, which would mean 233 hours or about 24 days of 10 hours each per mile. To this must be added about 30 cts. per joint for cost of splice bars and other pieces used. Such a joint made in the usual way with fish plates and bolts would cost about $1.80 for material, exclusive of copper bonds and all labor. Cast joints, that is, those in which from 50 to 120 lbs. of cast iron is poured about the rail ends, vary in cost from $2.00 to $3.00 per joint.

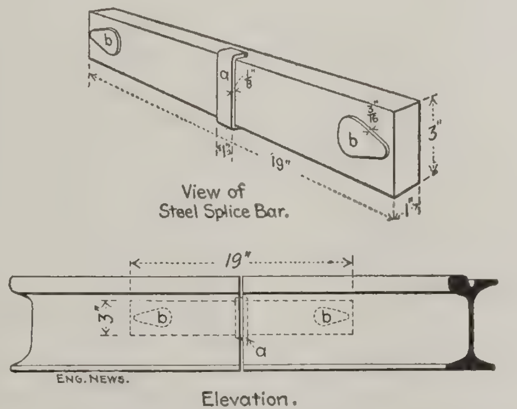

Fig. 4.—Steel Splice Bar Used, Showing Welding Points and Position of Splice with Reference to the Rails.

◆

THE SMOKE NUISANCE in the railway tunnel in St. Louis is creating some agitation in that city, and efforts are being made, by the newspapers and by business men's organizations, to have an ordinance passed to secure its abatement. The "Star" is carrying on a "crusade" in favor of the ordinance, which is to compel the Terminal Railroad Association "to rid the tunnel of its blackness, foulness and disease-breeding germs by methods of illumination and ventilation." That the St. Louis tunnel is black and its atmosphere so thick with smoke as to be unbreathable every traveler who has passed through it knows, but that it contains any germs, disease breeding or other, is doubtful. Sulphur fumigation is an effective method of killing germs, and the tunnel is well fumigated every time a train passes through it.

◆

THE HUDSON RIVER TUNNEL bondholders, through their trustees, the Farmers' Loan & Trust Co., of New York, and Mr. J. H. B. Kendall, of London, England, have made application to the New Jersey Court of Chancery for an order to sell the property in view of foreclosure proceedings on the mortgage of $4,000,000. It is expected that the order will be granted, when, it is stated, it is the intention of the bondholders to reorganize the enterprise and complete the tunnel. The status of the tunnel work was given quite fully in our issue of Nov. 25, 1807.

◆

ANOTHER LONDON UNDERGROUND RAILWAY is under consideration, and as the company, known as the Great Northern & City Ry. Co., is capitalized at $8,000,000 and includes a number of prominent railway men, it is quite likely the road will be constructed. The plan is to excavate two 16-ft. tunnels three miles long, connecting the Finsbury Park Station of the Great Northern Ry. and Moorgate St. in the city proper. The regular steam suburban trains will be hauled through the tunnel by electric locomotives, making the trip in 12 minutes.

◆

A ROYAL COMMISSION ON SEWAGE TREATMENT and disposal was recently appointed in England and is now holding meetings. The London "Surveyor" deprecates the fact that the press is excluded from the sittings.

◆

TELEPHONE SUBSCRIBERS IN RUSSIA NUMBER 21,590, of which 11,171 are supplied by the Bell Company, the remainder by the government. The company has 15 exchanges in 11 districts, including St. Petersburg, Moscow, Warsaw, Odessa, etc. The government has 80 exchanges in 67 districts, requiring 2,875 miles of lines and 15,130 miles of conductors against 848 miles of company lines and 15,580 miles of conductors. The charges are: 5.7d (12 cts.) for three minutes; 11.4d. (23 cts.) for the use of trunk lines up to 33 miles and 1s. 7d. (48 cts.) for distances of about 65 miles.

◆

AN ACETYLENE GAS PLANT has been installed in New Milford, Conn., for public lighting purposes. The holder has a capacity of 300 cu. ft. There are four generators, each holding 150 lbs. of carbide. The connections are such that water is permitted to gradually flow into one generator until the carbide is consumed, when it is automatically switched to the next generator, and thus the pressure and supply are maintained.

◆

THE "GOLD FROM SEA WATER" ENTERPRISE of the Electrolytic Marine Salts Co., of North Lubec, Me., has suspended operations and the "inventor" of the process and manager of the company, "Rev. " P. F. Jernegan, has absconded after having received $338,000 of the "profits," which were derived not from sea-water but from the stockholders. He sailed for Europe under an assumed name after having converted about $100,000 cash into government bonds in New York city, and his arrival at Havre on his way to Paris has been reported by cable. Steps have been taken to have him shadowed by detectives in France until papers can be sent charging him with embezzlement, on which his extradition may be secured. It is said that about $300,000 out of the $10,000,000 capital stock of the company was subscribed for in Newburyport, Mass., by bank directors and leading business men, who were led to subscribe through their confidence in the judgment of Mr. A. P. Sawyer, a local capitalist, and Mr. W. R. Usher, a large shoe manufacturer of that city, both of whom were directors in the company. One report says that $2,400,000 of the stock has been sold at par, that 45% of the money received went to the promoters, 20% to the "financial agents," and the remaining 35% into working capital, some of which was expended in the construction of the works at North Lubec, upon which 600 men have been engaged. The New York "Herald" of July 31 gives an interesting account of the preliminary experiments of the "inventor," near Providence, R. I., by which he obtained his first contributions of capital. It appears that a small shed was built at the extremity of a long slender wharf projecting from the shore of Narragansett Bay, and through a hole in the floor there was lowered by means of a windlass a large box containing a pan of mercury. An electric battery supplied by the "inventor" was applied during a whole night in the presence of some capitalists from Middletown, Conn., who had brought with them the mercury. The next morning the mercury was lifted from the water and given to a chemist who assayed it, and found in it $4.50 of gold, and thereupon the capitalists, much pleased, paid the first installment on their investment. The deception in the experiment, according to the detective, consisted in a diver's proceeding under water during the night to the box, pouring out the mercury, and substituting for it another lot of mercury containing gold. Upon this basis was floated the $10,000,000 company. Its success in obtaining gold at North Lubec was attested by its sending frequently to the New York Assay office "gold bricks" containing each about $2,000 of gold, and the exhibition of similar bricks at the company's office in Boston. The "gold from sea-water" scheme thus appears to have been one of the most gigantic swindles of recent years. It was similar in many respects to the Electric Sugar Refining swindle in New York city in 1884, by which many prominent business men, including even sugar refiners, were victimized. One of the operators in that scheme was convicted and sentenced to nine and a-half years' imprisonment. It is to be hoped that a like fate will meet the Rev. Jernegan and his accomplices.

◆

ANNUAL CONVENTION OF THE AMERICAN SOCIETY OF CIVIL ENGINEERS.

The thirtieth annual convention was held at Detroit, Mich., July 26 to 29, the headquarters being at the house of the Fellowcraft Club, the use of which was kindly tendered by its Board of Governors. A special train was run from New York, over the Lehigh Valley and Wabash railways, and special accommodations were provided by the Wabash R. R. for members from Chicago and St. Louis. There was a large attendance, both of members and guests.

The opening session was called to order about 10 a. m., July 26, Mr. A. Fteley, President of the Society, being in the chair. In consequence of the absence of the Mayor, Rev. Dr. Arnold, of Detroit, delivered the address of welcome, which was responded to by Mr. Fteley. The President's annual address was then read by the Secretary, an abstract of which we gave last week.

After the reading of the address, chairmen of the district committees to select members of the nominating committee were appointed by the chair. It was then suggested that the discussion of the proposed amendments to the constitution should be taken up, but on motion of Mr. Geo. S. Morison it was voted to defer this until the time set for it upon the program. The meeting then adjourned.

The afternoon session was devoted to a discussion of the paper by Messrs. Charles D. Marx, Charles B. Wing and Leander M. Hopkins, on "Experiments on the Flow of Water in the 6-Foot Steel and Wood Pipe Line of the Pioneer Electric Co., at Ogden, Utah." Mr. Henry Goldmark gave a brief synopsis of the general points of the paper, after which some written discussions were read by the Secretary, in which doubts were expressed as to the accuracy of the results of the experiments, in view of the conditions under which they were made. Mr. Kuichling also expressed somewhat similar views. Mr. John C. Trautwine, Jr., who was a member of the committee of the Franklin Institute, appointed to report upon the Venturi meter, thought the investigations made by these authors as to this meter are particularly valuable, especially as there is some doubt as to whether the piezometer measurements should be made at the top of the pipe or at the middle of the pipe. Experiments made at Philadelphia showed that the loss of head is less with this meter than with any other, but the loss increases as the square of the velocity. A 20-in. Venturi meter was placed on a certain supply main, and when several fire engines were pumping from this main to extinguish a fire they could not get enough water until the meter was cut out and the water sent through the by-pass.

At 3:30 p. m. the meeting adjourned, and the party boarded a number of electric cars provided by the Detroit Electric Ry. Co. for a ride about the city. The cars first went out on Woodward Ave., which is a handsome residence thoroughfare, and then along Jefferson Ave. to the water-works pumping station, where a short time was spent in examining the plant and in getting a photograph of the party. During this trip the width of the streets, their cleanliness, and the excellence of the pavement (mainly asphalt and brick) attracted considerable attention, especially from those interested in municipal work.

In the evening there was a steamer excursion on the Detroit River and St. Clair Lake, by courtesy of the Detroit, Belle Isle & Windsor Ferry Co. A band was provided, and dancing was indulged in on the upper deck.

The morning session on July 27 was called to order about 10:15 a. m. The first paper taken up was on "The Determination of the Safe Working Stress for Railway Bridges of Iron and Steel," by Mr. G. Herbert Stone. There was no discussion, nor were the written discussions presented, the President considering that the subject was too mathematical to be considered in the limited time that could be devoted to it. The Secretary then read a synopsis of Mr. Charles H. Snow's paper on "Marine Wood-Borers," an abstract of which was given in our issue of July 21. In the discussion it was stated that at San Francisco the teredo now attacks timbers which were formerly almost free from their attacks. Creosoting was considered one of the best protective methods, as it prevents decay as well as the attacks of borers, etc., but it is not universally reliable, as the oil will penetrate the softer rather than the harder parts of the wood, leaving the latter liable to attack. Mr. Harrod referred to the use of sewer tile slipped over the piles, the annular space being filled with sand, while Mr. Robert Moore described a process consisting of wrapping the pile with cloth treated with a certain mineral cement. One member thought that metal piles will be the most practicable solution of the question, especially in view of the low cost of iron and steel. The discussion began to drift towards methods of protecting piles, but the President ruled that this was not in order, and limited the discussion to the subject of the borers themselves. Mr. Wegmann said that while the limnoria is found in Boston harbor, the teredo is only rarely found, and is killed off by the severe winter cold. Cape Cod appears to be about as far north as the latter will reach.

The long and detailed paper by Mr. J. A. Ockerson on "Dredges and Dredging on the Mississippi River" was next taken up, the discussion being opened by Mr. Harrod. Work on the channels, he said, must be commenced as soon as the river has fallen to about mid-stage, and will allow of the surveys being made. The use of dikes and training works would necessitate extensive preparations at a multitude of places, as well as large gangs of men and extensive plant to put in these works. One of the new dredges will be self-propelling, thus avoiding the trouble and expense of a tender. It is desirable to keep the delivery pipes as short as possible, as a pipe 1,000 ft. long will deliver 25 or 30% less than a pipe 500 ft. long. As the dredged channels are usually diagonal to the current he advocated depositing the dredged material on the downstream side of the cut or channel.

Prof. L. M. Haupt referred to the use of portable jetties or dams, which are used mainly on the crest of bars, and consist of steel panels, with mats, secured to piling. Jetties or training walls to increase the scour through channel could be made in the way suggested by Mr. Harrod. The portable dams have been used with success in water 10 ft. deep and over. They cost about $3 per lin. ft., and 250 ft. can be built in a day. Another member thought the paper should have given credit to Mr. A. B. Bowers for the development of the hydraulic dredging system, and still another considered that the tables of the results of tests were unsatisfactory, the tests of different dredges having been made under such different conditions that the results could not properly be compared.

The next paper was on "The Reservoir System of the Great Lakes of the St. Lawrence Basin; Its Relation to the Problem of Improving the Navigation of These Bodies of Water and Their Connecting Channels," by Capt. Hiram M. Chittenden, U. S. Engineer Corps. An abstract of this was read by Mr. James A. Seddon, the author of an appendix to the paper, giving "A Mathematical Analysis of the Influence of Reservoirs Upon Stream Flow." The author of the paper thought that it would be best not to attempt to modify the oscillations in the lake levels, and that if such modification should be attempted it could best be done by some form of movable dam rather than by a fixed submerged weir, at the outlet of Lake Erie.

The discussion brought out considerable opposition to the statements and suggestions of the paper, and Prof. J. B. Johnson considered that the acceptance of its conclusions would mean stopping all further improvement. Mr. Rafter thought the position taken in regard to the question of rainfall in the Great Lakes was incorrect, and presented a somewhat lengthy discussion on this point. Mr. George Y. Wisner and Mr. Lewis M. Haupt also took part in the discussion and presented views adverse to those of the author.

At the afternoon session, the district committees presented nominations for members of the committee to nominate officers for 1899, and the nominations were confirmed as follows:

District No. 1.—Henry G. Prout, New York city.
District No. 2.—J. W. Ellis, Woonsocket, R. I.
District No. 3.—Emil Kuichling, Rochester, N. Y.
District No. 4.—Lewis M. Haupt, Philadelphia, Pa.
District No. 5.—Prof. Ira O. Baker, Champaign, Ill.
District No. 6.—N. W. Eayrs, St. Louis, Mo.
District No. 7.—Andrew Rosewater, Omaha, Neb.

The next subject was the selection of the place for the next annual meeting, and the membership at large seemed to have taken even less interest than usual in the matter, the letter ballot having resulted in only 56 votes. Washington and Atlantic City received the highest number of votes, the number being five in each case. Then followed the usual amusing and mildly acrimonious discussion on the subject. Mr. George S. Morison suggested that the convention be held at some point in the extreme South in April, 1899, but after a good deal of desultory talk this motion was defeated by a vote of 68 to 28, the larger vote being in favor of leaving the matter to the Board of Direction without any suggestion from the meeting. Possibly the discomfort due to the heat which prevailed in the convention hall had some influence in this, the very idea of going South suggesting more heat. Prof. Fuertes favored Ithaca and Cornell University, and a motion by Mr. B. M. Harrod was carried, to the effect that the convention should be held at some place where the entire party can be accommodated in one hotel.

An amendment to the constitution was also carried, and without discussion. This amendment does away with the office of Auditor, and puts the work of that office upon the Secretary and the Finance Committee, thus saving the Society the sum of $1,000 per year.

The question of submitting the appointment of committees on "rail joints" and "paints and painting" to a letter ballot was then taken up, but the discussion turned largely on the powers of the meeting and the Board of Direction as to modifying the terms of the original resolutions adopted calling for the appointment of such committees. Apart from this, Mr. Don J. Whittemore deprecated the work of committees, on the ground that the Society ought not to undertake work of this kind, which, he believed, should be done by individuals for themselves. Mr. Berg and Mr. Seaman, however, expressed the opinion that investigations by committees are among the important purposes of the Society and that a committee can get information and do work which no individual can or will do. Mr. Morison did not approve taking up the entire broad subject of rail joints, but thought a committee ought to be appointed to prepare standard sections for angle bars to fit the so-called "Am. Soc. C. E." standard sections of rails. The vote was 9 against to 46 in favor of submitting the question to letter ballot.

The subject of paints and painting, however, was considered to be of a somewhat different character, the great objection appearing to be that the inquiry would inevitably run foul of patents and manufacturers, and it was eventually decided that this proposed investigation should be dropped, and not submitted to letter ballot.

This concluded the business proceedings and the meeting then adjourned.

On Thursday, July 29, a large party left the Brush St. Station at 9.15 a. m., on a special train for Port Huron, provided by the Grand Trunk Ry. At Port Huron the party boarded a train of new gondola cars fitted with seats, which train was then run through the St. Clair tunnel to the Canadian side, and then back again. The train was pushed through in each direction, so as to have no trouble or discomfort from the smoke and gases from the engine. It is interesting to note that the huge tunnel engines, having ten driving wheels, are no longer fitted with side tanks, but have large tenders, as is the practice with ordinary road engines.

The Grand Trunk Ry. train then carried the party to the St. Clair River, where the steamer "Pleasure" was in waiting, and lunch was served as soon as the party was on board. The steamer started about 12.30 p. m., and after a very delightful trip down the St. Clair River and lake and the Detroit River, reached Detroit about 5 p. m.

The final session was called to order about 10 a. m., July 29, when the paper by Mr. D. A. Molitor on "Three-Hinged Masonry Arches, with Special Reference to Long Spans," was taken up. Mr. Goldmark, who opened the discussion, referred to the theoretical advantages of the three-hinged arch, but considered that it would have greater deflection than a solid masonry arch, and that therefore it would be inferior to the latter for railway bridges. Furthermore, as the arch masonry is but a small percentage of the total masonry in the structure, the slight saving in material by the use of a three-hinged arch is of but little importance. M. W. G. Berg took a similar view, and thought that the advantages of this type of arch would probably be more balanced by the increased difficulty and labor of design and construction.

Prof. J. B. Johnson, however, thought that a distinction should be drawn between difficult and uncertain computations, and thought while those for a three-hinged arch may be difficult those for a solid arch are very uncertain in results. If the principle is correct, the cost of making the necessary computations will be as nothing compared with the saving in cost of the structure.

After this, a series of resolutions of thanks to local authorities, transportation companies, etc., was adopted, and the convention then adjourned.

In the afternoon a party went down to Wyandotte on a parlor car of the electric railway to visit the shipbuilding yard of the Detroit Dry Dock Co., where the iron freight steamer "Troy," for the New York Central R. R., is now being completed.

In the evening a reception was held at the Detroit Club, and was a very sociable and enjoyable occasion.

The meeting was eminently successful, the only drawback being that the party was distributed among several hotels, so that there was less opportunity for general sociability and the making of acquaintances than when the entire party is accommodated under one roof. This led to the adoption of a resolution, as already noted, to the effect that the next convention should be held at some place where all the members and their guests can be accommodated in one hotel. The attendance was exceptionally large, there having been about 230 members and 300 guests present. With the exception of one or two very hot days, the weather was exceedingly pleasant. The Society was most hospitably entertained, and all the excursions were enjoyable and were managed without a hitch. As to the business part of the proceedings, perhaps the less said the better; most of the papers were presented in a perfunctory way, considering their value and importance, and the discussions were in too many cases brief and unimportant. It is possible that at some future day the Society will boldly omit technical papers and discussions entirely from its summer meetings.

THE POLLUTION OF THE PASSAIC RIVER is to be studied anew by a third commission. The eight members of this commission have just been appointed by Mr. Foster M. Voorhees, Acting Governor of New Jersey, under an act passed by the state legislature of 1897, providing for a state commission to consider the subject of the pollution of the rivers and streams of New Jersey. While the act is general in character, the popular conception of it seems to be that it is intended to be applied to the Passais River only, and all of the eight commissioners reside in cities or towns affected by the Passaic River problem. The commisioners are to receive not over $1,000 per year for their services, and may expend $25,000 in their work, subject to the approval of the governor of the state. The expenses of the commission are to be apportioned among the communities benefited. The members of the commission are as follows: Messrs. Wm. T. Hunt, Editor of the Newark "Sunday Call," and H. C. H. Herold, President of the Newark Board of Health; Chas. W. Fuller, City Attorney of Bayonne; Jas. A. Exton, M. D., of Arlington; Wm. Kent, M. Am. Soc. M. E., Associate Editor of Engineering News, of Passaic; Elias J. Marsh, M. D., and John Hinchliffe, Mayor, of Paterson; and Chas. F. Harrington, of Bergen Co.

MUNICIPAL OWNERSHIP OF WATER-WORKS continues to make rapid headway. On July 31 the plant of the Duluth Gas & Water Co. was formally transferred to the city of Duluth, thus ending the long struggle described in our issues of Dec. 16, 1897, Jan. 20 and May 5, 1898. At Des Moines, Ia., the people vote on Aug. 29 on buying the plant of the Des Moines Water-Works Co., formal agreements for the purchase having been made between the officials of the city and company. The Great Falls Water-Works Co., of Great Falls, Mont., has just accepted the city's offer of $375,000 for its plant. Several other places have recently changed to or voted for municipal ownership, while Indianapolis, Denver, Los Angeles, Pasadena, Cal., Cripple Creek, Col., Fulton, N. Y., and many other places, big and little, have the subject under discussion.

◆

WORK ON THE MASSENA CANAL, says the Watertown, N. Y., "Standard," is rapidly progressing. Seven steam shovels are at work on the ridge near the St. Lawrence, and two of these Vulcan shovels have a capacity of 1,000 to 1,500 cu. yds. per day of 10 hours. Cableways are being put up for Vivian scrapers and for transporting material, the latter is a 2½-in. steel cable stretched from two towers across the Grasse River, and capable of carrying a 10-ton bucket.

◆

HIGHER SPEED IN NEW BATTLESHIPS was decided upon on Aug. 9 by the Naval Board of Construction. But the board opposed making new designs for these ships, and recommended that bids be opened on Sept. 1, as originally proposed. This action is taken in the hope that the builders will submit plans and bids for faster ships, and the Cramps and the Newport News shipyard have already promised to send in such bids. Engineer-in-Chief Melville dissents from the recommendation of the board, and sends in plans of engines for speeds of 17 and 18 knots; but for the latter speed he wants 600 tons additional displacement if the 1,200 ton coal capacity and 6,300 knot steaming radius are to be preserved. The inherent danger in increasing speed without proper increase in displacement will be a crowding of machinery and a continuance of unsufferable heat conditions in the fire and engine rooms.

◆

THE TORPEDO BOAT "MACKENZIE," built at Hillman's shipyard in Philadelphia, on Aug. 5, made 23 knots on its builder's trial trip. The contract speed was 20 knots. But a boiler tube blew out on her return trip and four men were seriously burned. On the same day the torpedo boat destroyer "Farragut," a 30-knot boat, made a preliminary trial at San Francisco. She was built at the Union Iron Works, and with 3,000-HP. developed out of her 5,800-HP. contract power, she made 26 knots.

◆

THE COST OF LARGE CALIBER AMMUNITION, in the present war is very great. A 13-in. gun, firing a projectile weighing 1,100 lbs., consumes 550 lbs. of brown prismatic powder, costing from 30 to 33 cts. per pound. At the lower price the powder for a single discharge costs $165. The common 13-in. shell is said to cost $116.63; but the armor-piercing projectile costs $418. To these items musts be added cartridge-bags, primers, freight, etc., amounting to about $15; or, $296.63 for the shell discharge, and $588 for the discharge of an armor-piercing projectile. As the 13-in. gun can be discharged about 25 times in an hour, the work of one gun for an hour may cost the government about $15,000. The 8-in. gun costs about $65 for each shot; the 5-in. rapid-fire costs $33; the 6-in. brech-loading shot costs about $40, $14 being for the powder; and each round of a Hotchkiss 6-pdr. gun is estimated to cost $5.70, and a 1-pdr., $1.12. Whitehead torpedoes cost $2,500 each, and a Howell torpedo, $2,200.

◆

ONE FLOATING DOCK, instead of two, will be purchased by Commodore Endicott, Chief of the Bureau of Yards and Docks, for immediate use in Southern waters. This order was issued since peace representations were made, and negotiations have been concluded for towing the Perth Amboy dock, of 2,300 tons capacity, to Key West.

◆

A COALING STATION WILL BE ESTABLISHED by the Navy Department at the U. S. Naval Station, New London, Conn., and bids have been asked for the work. The specifications call for the erection of coal pockets or sheds with a capacity for about 10,000 tons of bituminous coal on a basis of 45 cu. ft. per ton. The plans contemplate the receipt of coal by rail over an extension now being built through the station, and also by water, suitable coal handling and conveying apparatus being provided for rapidly unloading or loading vessels or lighters. Only the most approved and substantial methods and construction will be used.

◆

GREAT ACTIVITY IN SHIPBUILDING is expected to follow the end of the present war. As a result of the number of vessels impressed into the government service, many steamers are now being built to replace them. Wm. Cramp & Son are building a steel twin-screw steamship, 360 ft. long, for the New York and Cuban Mail Steamship Co., and four steel steamships, each 280 ft. long, for the American Mail Steamship Co. At Chester, Pa., two steel steamships, each 260 ft. long, are being built for the Old Dominion Line; Harlan & Hollingsworth, of Wilmington, Del., is constructing a 274-ft. steel steamer for the Merchants' and Miners' Transportation Co., of Baltimore; and at Newport News, three new Morgan liners, two new Cromwell liners and two new Pacific Mail steamships are on the ways.

◆

THE THREE 2,500 HP. GENERATORS and steam engines constructed by the Westinghouse Electric & Mfg. Co., of Pittsburg, Pa., for the Metropolitan Electric Supply Co., of London, England, were inspected on July 30 by a large number of engineers. Each of these machines include a marine-type, vertical-cross compound engine of 2,500 HP. and a direct connected 2,000-HP. 500-volt two-phase generator, with a revolving armature. The engines are capable of operating at speeds between 116 and 145 revolutions per minute.

◆

THE MOST SERIOUS RAILWAY ACCIDENT of the week occurred Aug. 8 on the New York, New Haven & Hartford R. R., at Canton Junction, Mass. A special mail express, composed of four cars, jumped the track while running at a high rate of speed, owing to the breaking of a bolt in the cross beam of a siding switch. Three postal clerks were killed and seven were injured.

◆

THE HAMBURG-AMERICAN LINER, "Fuerst Bismarck," has made a new record, from New York to Cherbourg, of 6 d. 13 h. 50 m. This beats her previous best record by about one hour. The "Bismarck" held the Southampton eastward record for four years. It was taken from her in September, 1897, by the "St. Louis," which made the trip in 6d. 10h. 14m., and the Southampton record is now held by the "Kaiser Wilhelm der Grosse," at 5 d. 17 h. 8 m., made in November, 1897.

AMERICAN EXHIBITORS at the Paris Exposition will, if present indications continue, make a creditable showing. Already applications have been received from over 600, and the 150,000 sq. ft. allotted to the United States will undoubtedly prove too small, and a request will be made for a total of 500,000 sq. ft. So far, ten electrical companies alone have asked for 75,000 sq. ft. The prominence given to the United States by the present war has had its effect abroad, and it is expected that little trouble will be experienced in obtaining the extra space.

◆

ARMOR-PLATE BANK-VAULTS are being built by the Carnegie Co. for the Union Trust Co., of Pittsburg, and the Philadelphia Saving Fund Society. The steel vault of the Union Trust Co. will be built of single 6-in. plates. with an 8-in. plate, weighing 46,150 lbs. and 234 × 114 ins., in the front. This front plate will be reinforced by a rolled steel plate 6½ in. thick and weighing 38,200 lbs. The door will be circular, 86 in. diameter and 3 ins. thick at center, and 6 ins. thick on the edges, ground to a gas-tight fit. The clear space within the vault will be 18½ × 16½ ft. and 9½ ft. high. No bolts are used in joining the plates, as the work is machined out and dovetailed so as to form a solid box resting on a masonry foundation. This is said to be the first use of solid armor-plate for this purpose as a substitute for the usual laminated steel construction.

◆

THE PHILADELPHIA STORM OF AUG. 3 eclipsed all previous records. The rainfall record was 5.48 in. in 1 h. 50 m., and a boy and horse were killed by lightning. A man was drowned in a cellar in a sudden and enormous inrush of water from the street.

◆

A STEEL VERTICAL LIFT BRIDGE, with steel towers 213 ft. high, has been built by French engineers, at Bizerte, Tunis, over the entrance to Lake Bizerte. The span is not noted, but the bridge is lifted by cables and pulleys, by a 6-HP. engine, in 40 seconds.

◆

ALUMINUM HORSESHOES have been tested in the Russian cavalry and seem to prove satisfactory. It is reported that they wear out less rapidly and are less affected by mud and moisture than the ordinary shoe. The difference in weight is 2½ oz. per shoe.

◆

A TELEGRAPH LINE FROM CAIRO to Cape Town, in Africa, is talked of, with Mr. Cecil Rhodes as chief promoter. The proposed route would be from Fort Salisbury to the Zambezi, near Tete; thence to Zomba and along the west coast of Lake Nyassa to Karonga and Lake Tanganyika. At the latter point it would be necessary to lay a cable to the head of the lake; or, obtain the permission of Germany or the Congo State to run an overland line through that territory. A telegraph line is now said to extend as far north as Lake Tanganyika; and from Cairo south it almost reaches the site of old Khartoum, or the junction of the Nile and the Atbara.

◆

THE CONSERVATOIRE DES ARTS ET METIERS, on June 24, celebrated the centennial of its installation in the old priory of Saint-Martin des Champs, in Paris. Descartes is credited with first conceiving the idea of a museum of models for the use of artisans; but the French Convention ,on Oct. 11, 1794, realized this idea by a decree then issued; and on June 10, 1798, the Conservatoire was definitely organized and installed in its present building. The decree called for the collection of machines, models, tools, designs, and books of all kinds relating to the arts and manufactures, and the construction and uses of these machines, tools, etc., were also to be made plain. Free lectures are given here upon the application of science to the industrial arts, upon mechanics, chemistry, industrial economy, descriptive geometry, industrial legislation, agriculture, etc. Original research is here conducted under the ablest men obtainable, and the scientific library now numbers 40,000 volumes. The building itself is a beautiful structure of the 11th, 12th and 13th centuries.

◆

THE FRANKLIN TUNNEL, now under construction on the Valley Railway terminating on the Bay of San Francisco, will be 5,600 ft. long. Work was commenced on the approaches in December, 1897, under the Engineer, Mr. A. S. Riffle. This tunnel, named after Franklin canyon close by, is 22 miles from Point Richmond, the terminus of the Valley Railway, and the road now being built will connect at Stockton with the present line of the Valley road. This road will require five tunnels through the Coast Range of mountains, one at Point Richmond, 825 ft.; a curved tunnel of 1,100 ft. at Pinole, and two others of 1,300 ft. and 300 ft., besides the Franklin tunnel. The contractors for the latter work are Folev Bros. & Muir, of St. Paul, Minn., and the estimated cost is about $400,000. The work is being pushed from both ends, at the present rate of 6 ft. daily on the eastern end and 8 to 12 ft. daily at the west. The tunnel lies about 400 ft. below the summit of the ridge pierced.

COVERED STORAGE ROOM FOR RAW MATERIAL; YOUNGSTOWN BRIDGE CO.

The advantages to be gained in the cheapness and comfort of handling and in the ease of marking and laying out the various rolled shapes used in bridge work has led a few bridge companies to build covered storage yards for their raw material. In the accompanying view such a covered space, forming a part of the main truss shop of the Youngstown Bridge Co., of Youngstown, O., is shown quite clearly, with the assorted piles of angles, Z-bars and other shapes fully protected from the rain and snow. The view also shows some features of the overhead trolley construction and the heating arrangements for these shops, which, as we have previously noted, were entirely rebuilt last winter. The advantages to be gained by so fully protecting the material from the weather are not confined to economy in labor and time in handling the material at the bridge shop. Recent investigations have shown that the durability of paint is very materially increased by having the metal free from corrosion and perfectly clean when the paint is applied. These conditions are much more likely to prevail if the material is protected from the weather from the first, than if the manufacturer is depended upon to clean thoroughly in the rush of work all metal work to which paint is applied before shipment.

INTERIOR OF MAIN TRUSS SHOP OF THE YOUNGSTOWN BRIDGE CO., SHOWING RAW MATERIAL STORED UNDER COVER.

THE NEW WATER-WORKS INTAKE TUNNEL FOR CLEVELAND, OHIO.

(With single-page plate.)

The longest water-works intake tunnel yet attempted in the world, so far as we know, is now being constructed at Cleveland, O., beneath Lake Erie. It will be 26,000 ft. in length, 9 ft. in diameter, in the clear, have an estimated daily capacity of 170,000,000 gallons, and will terminate at an intake crib in water 49 ft. deep, located as shown by Fig. 1. On June 17, 1898, when a member of the editorial staff of this journal visited the work, the shore shaft and one temporary lake shaft had been sunk and about 8,500 ft. of tunnel had been driven, besides which the second temporary shaft was down about 98 ft. below the water level and the permanent steel intake crib had been launched and was being finished preparatory to being towed to and sunk in place. This article, however, describes the work up to July 31, as noted further on.

Thus far the work has progressed without more than the minor incidents to be expected on all such jobs, with the exception of two explosions in the tunnel and the encountering of bad material in the shaft of temporary crib No. 2, as described further on. Mr. M. W. Kingsley, M. Am. Soc. C. E., Superintendent of the Water-Works, is the chief engineer of the work, and Mr. C. F. Schulz is first assistant engineer.

Before proceeding to describe the new tunnel and accessories a few words may be said regarding the old works and the report recommending the improvements now in progress.

The Original Tunnels and the Expert's Report.

The present water supply of Cleveland is taken from the lake at a point 6,006 ft. from the shore, although the tunnels are somewhat longer, through two intake tunnels, as shown on the map, Fig. 1. The first tunnel built was 5 ft. in diameter and 6,662 ft. long. Later this tunnel was extended for 2,580 ft., from the shore to the pump wells, the diameter being 5½ ft. and 6 ft. About 1890 a second tunnel was completed, leading from the old intake crib to the main pumping station. The diameter of this tunnel is 7 ft. and its length is 9,200 ft., including the shore end.*

The combined capacity of the two old tunnels is placed by Mr. Kingsley as at least 120,000,000 gallons, at all stages of the lake. By lowering the pumps and the conduits connecting with them it is expected that 150,000,000 gallons per day can be drawn through these tunnels, even after they are extended as a single tunnel of large diameter, as recommended in the report mentioned below.

Early in 1896 a commission composed of Messrs. Rudolph Hering, G. H. Benzenberg and Desmond FitzGerald, Ms. Am. Soc. C. E., reported on improvements in the water supply and sewerage systems of Cleveland. They recommended that water should be drawn from a new intake crib about four miles from the shore, through an extension of the present tunnel; that intercepting sewers should be built to convey the sewage some ten miles, measured along the shore, from the water-works intake; and that a flushing tunnel be built to dilute the water of the Cuyahoga River. This report was approved, except in some details, by Messrs. M. E. Rawson, Chief City Engineer, and M. W. Kingsley, M. Am. Soc. C. E., Superintendent of the Water-Works. Mr. Kingsley advised the construction of an independent tunnel from the proposed intake to a new pumping station on the opposite side of the city, as is being done. Instead of a submerged intake crib, as recommended by the commission, the projecting structure shown by the accompanying drawings is to be used. The intercepting sewer, it may be added, is now well under way, but the flushing tunnel has not been started, which delay accords with the suggestions of both Mr. Hering and Mr. Kingsley.

The Shore Shaft.

The work of driving and lining the tunnel is to be carried on finally from four shafts, a shore and inlet shaft, respectively, and two temporary shafts, thus giving six headings. The shore shaft was completed Dec. 18, 1896. Its dimensions and general character are shown by Fig. 2. It was sunk some 60 ft. by the use of a cast-iron shoe and ordinary excavation, the shoe having a cutting edge and the curb being loaded as found necessary. Steel cylinders of ¼-in. plate were riveted on the shoe and then on each other as it sank, and a brick wall built up inside the cylinder, as shown. After the shaft had been carried down as far as was deemed practicable by this means, a pilot shaft about 6 ft. sq., lined with heavy oak sheathing, was sunk to the level of the bottom of the sump. This shaft was then enlarged by sections and the brick lining put in from the bottom upwards until some 10 or 12 ft. from the cast-iron shoe. The weight of the curbing caused it to sink down, bending all supports placed under it, until it rested on the lower wall. The two walls not coinciding perfectly, the latter was rebuilt, after an air lock had been placed in the upper section. The location of the two temporary cribs is shown in Fig. 1. The cribs are very solidly built of timber, in pentagonal form, having outer sides 54 ft. in length. The first course consists of 12 × 12-in. timber framing, upon which is a solid floor of two courses of 12 × 12-in. timbers, with 3 × 12-in. plank, laid flatwise and calked, between them. All four courses are of pine, drift-bolted vertically and horizontally, besides which many screw bolts were used. The outer and inner walls of the crib and an intermediate wall are of hemlock timbers for 40 ft. above the pine bottom just described, and of pine for the next 16 ft., or to the floor line, the timbers being of 12 × 12-in. stuff. Vertical drift-bolting is used freely in these walls and proper bracing is also employed. A plan of the crib at the floor line and a cross section of the superstructure are shown by Fig. 3. The corners of the cribs for a distance of 14 ft. below the floor line are protected by ¼-in. steel plates and there is a 3-ft. band of the same material around the cribs at the water line to protect the cribs from the action of moving ice. The construction of the cribs was begun on shore and finished inside the breakwater after launching them.

The Temporary Cribs and Shafts.

The temporary shafts are 8 ft. in diameter inside and are in 43 ft. of water. Ouly the one nearest the shore has yet been completed. For about 25 ft. above the top of the ring of the tunnel the shaft is lined with 12½ ins. of brick. Next comes a cast-iron cylinder with a 1¾-in. shell and inside flanged and bolted joints, lined with 4 ins. of brick. The upper 9 ft. of the shaft is of steel. This shaft was sunk in much the same way as the shore shaft, the shell having the flange on its lowest section omitted to form a cutting edge'

Difficulties at Temporary Shaft No. 2.

At the second temporary crib the sinking of the shaft has met with delays, which can be best described by quoting from a letter to this journal written by Mr. Schulz, First Assistant Engineer, which brings the account down to July 31:

> Work proper on this shaft was begun on Jan. 14, 1898, and by Jan. 25 eight cylinders were bolted together, making the total length of the shaft 72 ft., 18 ft. of which had been forced into the lake bottom, the upper 8 or 9 ft. being sand, while below that was soft blue clay. The ninth cylinder was then added, having first been converted into an air lock by bolting to the end flanges heads or diaphragms having a door each and made of steel plates stiffened with channel irons. The shaft was then ready to have an air pressure applied to complete the lower part under pressure. Before this the water had been pumped out and the shaft found to be perfectly dry.
>
> The work was now delayed, because the air compressor for this crib had not arrived, and after it did arrive (on

---

*A detailed description of the Cleveland water-works from their start to the close of 1877, including the construction of the first tunnel, was published in Engineering News for April 26, May 3 and 10. and June 14, 1879. Subsequent articles on various phases of these works were published in our issues of April 23, 1881; March 19, 1892; April 5, 1894; and Feb. 20, 1896, the latter being an abstract of an expert's report on the new supply.

Feb. 3) the ice in the lake prevented its being taken out until Feb. 11, when it was set up and connected with the shaft ready to put on the pressure. Digging was resumed in the shaft Feb. 18. During this time, i. e., from Jan. 25 to Feb. 18, or 23 days, this shaft, in order to prevent its settling further, had been held in timber clamps, which were secured to the wall enclosing the well of the crib. There had been a strong movement of ice in the lake at different times from Feb. 1 to 10, which shook and jarred the crib considerably, and the shaft being held in the clamps, this shaking and jarring was communicated to it, so that it worked down into the clay bottom about 3¾ ft. farther. It, however, remained perfectly dry during all this time.

On Feb. 21, the cast-iron shaft, now 81 ft. long, was in its proper position and embedded for 25 ft. in the lake bottom, with 3 ft. excavated below the cutting edge, ready for the masons to build the brick lining, consisting of three rings of brickwork, making a wall 12½ ins. thick. The air pressure was now put on, 18 lbs. per sq. in. being maintained, and the masons were sent in at 11 p. m. About an hour later a little water was observed to be trickling in through what seemed to be a vein of sand about 6 ft. wide and a few inches thick. The flow of water gradually increased, so that by 2 a. m. there were about 18 ins. of water in the shaft and the men were compelled to quit work. As no provision had been made for taking care of or pumping out any water, the shaft slowly filled up, there being 11½ ft. of water in it at 8 a. m., although the air pressure had been increased to 25 lbs.

The contractors decided to order two more cylinders and to force the shaft 18 ft. farther into the clay before again attempting to put in any brickwork. While these were being made, the air pressure was let off from the shaft, and the water in the shaft then rose to the lake level, indicating that the water had forced its way down on the outside of the shaft, or through some cracks in the clay extending from the bottom of the shaft to the bottom of the lake.

The tenth cylinder was delivered on March 10 and put in position on the following day. The water was then removed from the shaft and excavating commenced. It was found that the clay, also some sand and gravel, extended up in the shaft to about 9 ft. above the cutting edge. The shaft settled about 4 ft. on the second day after resuming operations. On the following day the eleventh cylinder was bolted on, making a total length of shaft of 99 ft. Excavating was then continued, the material being soft clay. Subsequently two cracks were discovered in the cast-iron cylinders, one in the second cylinder and one in the third cylinder from below. Both cracks were immediately under the top flange of these cylinders and extended a little more than one-fourth way around. The water now came in quite fast through these cracks, and also around sides of cylinders from below, which finally compelled the men to leave the shaft and allow it to fill again with water. The work was delayed on two other occasions, first by gas and water bursting up from below, and again by water coming in under the cutting edge of the shaft. Both times the shaft was allowed to fill up with water.

Permission was finally given the contractor to add a third extra cylinder, making twelve in all, or 108 ft. total, and to drive the shaft a few feet deeper than was originally planned in order to get into better ground for driving the tunnel. (The invert of the tunnel here was to have been 105 ft. below datum.—Ed.) In order to secure the cracked cylinders the top flange of the first and the bottom flange of the fourth cylinder were connected by rods about 18 ft. long, passing through the flanges of the two cracked cylinders and drawn up tight with nuts on both ends. The cracks were also calked with lead and a brick wall 8 ins. thick built inside the two cracked cylinders, the brickwork being laid in Portland cement mortar and thoroughly grouted. While this work was being done 40 lbs. pressure were maintained in the shaft. After this work had been completed and the clay again dug out to the cutting edge, on July 20, the air was allowed to exhaust from the shaft in order to sink it farther down, settling it 4 ins. in about one hour and then stopping. Air pressure was then again applied, the water pumped out and excavating continued until 3 ft. below the cutting edge had been taken out, when the air was again let off, the shaft sinking 21 ins. this time, but filling with water in a few hours.

After the water had been removed an examination showed that another cylinder had been cracked during this operation, being the sixth one from below; the crack being in the same relative position with the others. This is now being calked and secured by rods. This shaft is now, July 31, 108 ft. long and extends from 12 ft. above lake level, or 10 ft. above city datum line, to 52 ft. below the bottom of the lake.

It is our opinion that the most trouble has been caused by the leakage through the cracks in the cylinders, rather than by water following down outside the shaft and coming in under the cutting edge; and we were at first inclined to the belief that these cracks were due to the heavy strains produced in the shaft while it was held in the clamps and the crib was jarred and shaken by the moving ice. Against this theory, however, is the fact that the shaft was perfectly dry during all the time that work was suspended and for four days after it was resumed, and that the cracks themselves were not discovered until about 26 days later. This third crack occurring during the operation of forcing the shaft down indicates that the cause is to be sought in the ground through which it is being sunk.

When the tunnel is completed it will be arched over at the two temporary shafts. The shafts will then be filled with puddled clay to a depth of 20 ft. and for the remaining depth to the lake bottom with earth. All obstructions to navigation to a depth of 35 ft. below the water line will then be removed.

The Steel Intake Crib.

The permanent steel crib has an outside diameter of 100 ft. and a central well 50 ft. in diameter. A section of the crib is shown by Fig. 4, and two views of it under construction by Figs. 5 and 6. It has an octagonal pine timber bottom, 4½ ft. thick, the lower course being a frame and the three upper ones being solid, all the timber being 12 × 12 ins., except the outer ones, which are 12 × 18 ins. Radial partitions divide the crib into 24 water-tight bulkheads. The rings and partitions are of ⅜-in. steel plates, in 6-ft. courses, reinforced by angles at the joints and also at intervals along the radial plates. The rings are bolted to the timber bottom and also braced against it, triangular-shaped plates with angles bolted to their longer sides serving as braces. In each compartment and course there is one strut between bulkheads, and one tie piece between braces, all of angle iron, the struts being formed of two channels bolted together and to vertical gusset plates inserted at the top of each vertical joint in the bulkheads, four angles being used at these joints. All joints are riveted. The twelve inlet ports are designed to admit water to the shaft and tunnel at eight times the rated capacity of the latter, allowing a velocity of 4 ft. per sec. through the tunnel.

The metal work of the crib is painted with three coats of lead and oil, the first and third coats being of red lead and the second of white lead. Analyses of the lead were made from time to time to make sure that only pure lead was being furnished.

The timber bottom of the steel crib was constructed on land and the steel work started there after which the structure was launched to the breakwater and work continued until it was ready to be towed to and sunk in place. Fig. 5 shows the crib at the breakwater and Fig. 6 shows it in place.

The intake shaft will be about 10 ft. in diameter. As proposed, the first 18 ft. of the shaft, above the top of the tunnel lining, will be lined with a 16¾-in. brick wall. For the next 60 ft. the lining will be of 2-in. cast-iron cylinders, each 10 ft. in length, 4 ins. of brick being built inside this cylinder and carried on to the top of the shaft through the upper 30 ft. of steel cylinders. All the metal sections have inside flanged and bolted joints.

The Lake Tunnel.

The tunnel, as already stated, is 9 ft. in diameter in the clear, and is lined with three courses of shale brick, laid in mortar composed of one part of natural hydraulic cement and two parts clean sharp lake sand.

The grade line of the tunnel was designed to start at an elevation of 105 ft. below city datum at the shore shaft and also at the two temporary shafts, and to start at an elevation of 109 ft. below city datum at the inlet shaft. The tunnel is being built with a very slight up grade from each shaft so as to cause any water that may be encountered to flow towards the shafts. There will be three summits in the tunnel, not exceeding 2 ft. high each, which will be at the points where the different headings will meet. It is calculated that the air which will be entrapped at these summits will be absorbed by the water, as it will be under a pressure of about 43 lbs. when the tunnel is full of water.

Compressed air under an average pressure of about 20 lbs. is being used in building the tunnel, the locks being placed as already stated above in describing the shafts, except that the lock near the shore shaft has been moved out about 3,700 ft. beneath the lake. This lock is of boiler iron, 5½ × 17 ft., built into brickwork. The two locks at the next shaft are of greater length than the first one, so as to admit three instead of two construction cars. They are built of brick, with steel diaphragms, bolted together. The air supply is 4 ins. in diameter. The tunnel beyond the lock is ventilated by taking the air required for locking in and out through a 2½-in. pipe leading from the face of the work to the lock. A special air lock (of 6-in. wrought-iron pipe) is used to send rails, pipe and similar supplies into the portion of the tunnel under pressure, thus diminishing the waste of air caused by operating the large lock. The tunnel is lighted by incandescent lamps. The cars for sending in supplies and hauling out the excavated material are drawn by mules.

The tunnel excavation has been carried on by the ordinary methods employed for such work, except for a few feet at the scene of the accident. The material encountered has been mainly a stiff blue clay, in layers of ½-in. to some 6 or 8 ins. thick, with very thin layers of quicksand between them.

Accidents in the Tunnel.

Occasionally small pockets of gas were found, but the gas gave no trouble until, on May 11, a large amount of gas was encountered which gave rise to an explosion, from the effects of which eight men died subsequently. A mass of clay fell into the heading in advance of the brickwork, completely filling it for a length of 17 ft., the lining having been carried to a point 6,281 ft. from the shore shaft. At this point there was some 50 ft. of clay above the excavation. The cave-in extended up 20 ft., leaving about 30 ft. of solid material between its top and the lake bottom. The contractor requested permission to change the course of the tunnel, but this being denied work was resumed on June 13. The fallen material being loose, it was decided to hold it in place, while inserting the lining, by means of a steel cylinder. This was built up to the diameter of the outside of the brickwork with 18 × 24 × ¼-in. steel plates, bent to shape, with 3 × 3-in. angles riveted on each edge by means of ⅝-in. rivets, 3 ins. c. to c. The angles of the adjoining plates were fastened together with ⅝-in. machine bolts, five in each longitudinal and six in each circumferential joint, making 102 bolts in each ring of 17 segments. When the writer visited the tunnel this work was well under way and it was expected that twelve rings, or a length of 18 ft., would suffice to pass through the fallen material. Under date of July 31 Mr. Schulz sent us the following additional information regarding this break in the tunnel, as well as a description of a second break, which occurred on July 11, or just two months later:

> Eighteen feet of steel plate did pass through the fallen material and work was then carried forward in the usual way, except that shorter drifts were made, as the clay was quite poor, containing a large mixture of dry quicksand. Since the explosion on May 11, the contractors had changed their method of ventilation so as not to depend altogether on locking through the air-lock for exhausting the air from the face, but had extended a branch of the exhaust pipe through the air-lock, which was constantly blowing off air, and it was thought that this would prevent any re-occurrence of any accident from gas explosion. On July 11, however, while the masons were at work, another explosion occurred, which killed eleven men, or every one at the face of the work, the only men escaping being a mule driver and the locktender, who were both at the air-lock about 2,850 feet from where the explosion occurred. The tunnel had been completed to 6,541 ft., or 260 ft. beyond the point where the first explosion occurred. What caused it is not known; the electric lights were not extinguished, except for a distance of 700 ft. back from the face, the wires being torn down and the lamps broken in this part. The tunnel was not injured in any way, although a brick bulkhead 4¾ ft. thick, built across the tunnel at 6,200 ft. from the shore shaft, or 340 ft. from the face of the work, was completely demolished, the whole mass being hurled about 120 ft., carrying floor and tracks before it for this distance. A temporary bulkhead has been built in the tunnel at the face and work stopped for the present.

Instrumental Work in Locating the Tunnel and Cribs.

The following description of this part of the work was prepared for this journal by Mr. Schulz:

To reproduce the direction of the line in the tunnel as established on the surface, two plumb lines were suspended in the shore shaft, lined in with the transit on top, the bobs being steadied in oil, and the line was then produced in the tunnel by a transit set up about 50 ft. from these two lines and ranged in until the three points were in perfect alinement. The line was then marked by files on iron hooks, driven into the roof of the tunnel every 100 ft. The shaft not being vertical, the two plumb lines could only be placed about 2½ ft. apart. As this gave too short a base line by which to build the tunnel for any great distance, a 6-in. tube was driven from the surface down through the roof of the tunnel at a point 65 ft. from the shaft. The operation of plumbing down and producing the line in the tunnel was then repeated at three different times, with one plumb line in the shaft and one in the tube, giving a base line 65 ft. long. As the transit work interferes considerably with the transportation of spoil and material, the line was then very satisfactorily produced as the work progressed, for 400 or 500 feet, by stretching a fine line, 200 ft. long, always using the last two hooks as a range, and then checking the work with the transit. The grade of each section built is given with a straight edge and carpenter's level, and checked with the instrument once a week, or every 90 or 100 ft.

The intake protection crib is located 18,040 ft. from the breakwater light, bearing N. 32¼° W. This point was selected as complying with the recommendations of the sanitary commission to place the intake west of the river, and as not being too far west to make it impracticable to build the tunnel to a pumping station three miles east of the river. After this point had been determined, the line of tunnel was marked on the grounds of the proposed pumping station by a series of stakes. A base line, 3,800 ft. long, was then measured on the U. S. breakwater, west of the river, which runs parallel with the lake shore at a distance of about 3,000 ft. from it.

The positions of prominent points, such as the center of the old intake crib, center of Detroit St., school house, steam exhaust pipe of Society for Savings Building, breakwater light and center of shaft No. 1 (shore shaft) were then established, by triangulations, from this base line, to be used in determining the proposed positions of the different cribs by means of angles observed with a sextant.

In placing the two temporary cribs more attention was paid to locating their centers exactly on the line of the tunnel, so as to make it possible to build the tunnel in a straight line, than to have them any exact distance out from shore.

To determine the right location of the first temporary crib, which was to be 11,600 ft. distant from shaft No. 1, pound stakes, i. e., stakes about 65 ft. long used by fishermen, were driven in the lake on the line of the tunnel; one 100 and one 200 ft. from the proposed center of the crib. To determine the location of the first stake a fisherman's pound stake driver, equipped with a steam hammer and its own motive power, was run over the proposed line of tunnel as nearly as could be judged, and the position located approximately with a sextant, an anchor with buoy attached being thrown overboard the moment that the two objects, subtending the angle at which the sextant had been set, coincided. Four anchors, each about 300 ft. from this buoy and at right angles to each other, were then dropped and the stake driver was then, by means of lines attached to these anchors, hauled back and forth in the vicinity of the buoy until it was brought into the exact position as nearly as could be determined with the sextant. A stake was then driven and checked by an observer on shore stationed with a transit on the line of the tunnel, as previously marked, and who could plainly see the stake after it was driven and the driver removed to one side.

It was found that the stake was 0° 4′ 25″ south of the tunnel line, this angle corresponding to a distance of 16.5 feet; a second stake was then driven 16.5 ft. north of the first stake, and again checked with the transit on shore and found to be exactly on the line of the tunnel. A third stake was then driven on the line of tunnel at a distance of 100 ft. from the second stake, in order to have a range for the location of the crib in case it should be impossible (which proved to be the case) to see the shore when the crib was being placed in position.

The second temporary crib was located in the same way. After these cribs were sunk and built up their exact position was also determined; to be used as a basis in placing the intake protection crib.

Before the intake crib was taken out another base line was measured on the railroad right of way, on the east side of the river, commencing at the intersection of this line with the tunnel line and going westward 3,636.94 ft. By means of this base line the positions of the first and second temporary cribs and the old intake crib were determined independently of the west side base line and found to agree very closely, i. e., the distance from shaft No. 1 to center of crib No. 1, by the west side base line, was 11,613.1 ft.; by the east side base line it was 11,611.8.

As the distance determined with the east side base line was obtained more directly, this was adopted as being the more correct one and was used in calculating the angle for the proper location of the intake crib.

To determine this angle the distance from the old intake crib to temporary crib No. 2 was calculated, as well as the proposed distance, on the line of the tunnel, from crib No. 2 to the intake crib, and the included angle being known, the proposed angle at the new intake crib between crib No. 2 and the old intake crib was then determined. Before this crib was taken out three stakes were driven on the line of the tunnel, the same as for the temporary cribs. Four ship's anchors for hauling and holding the crib in exact position were then placed in the lake, two being placed parallel to the line of tunnel and two perpendicular to this line, at the proposed center of shaft in this crib; each anchor was about 350 ft. distant from this point.

The crib was taken out early in the morning on July 1, and was sunk by 10.20 a. m. The crib was controlled by five lines, two leading from one anchor to opposite sides of the crib so that it could be swung around as well as hauled back and forth, the object being to have the landing point directly towards shore. After the crib was secured to the anchors the lines were hove taut to hold it in position so that the proposed center of the shaft to be sunk from this crib should be exactly on the line of the tunnel and also the right distance away, this distance being determined and controlled by constant observations made with the sextant, stationed over this point.

The 24 4-in. gates to the compartments were then opened, care being taken to have the crib go down in a level position. When within about a foot of the bottom the crib began to surge to the southwest a little and touched bottom before it could be brought back to line, so that the proposed center of shaft was afterwards found to be 19 ins. south of the tunnel line. This point can, however, be shifted somewhat, so that this divergence is of no consequence practically. The crib was also found to be 8 ins. out of level in 100 ft. (its diameter), which accounts for 5 ins. of this 19 ins. divergence. Up to July 27 about 12,000 tons of stone had been thrown into the crib, and about 1,500 tons of large rip-rap stone had been placed around it.

After the crib had been filled with stone to its full height of ten courses, or 60 ft., as now built up, and when about 6,000 tons of rip-rap have been placed around it, it will be leveled by means of the eleventh course. A parapet 7 ft. high will then be added and a house 44½ ft. sq. be built in the center of the crib. It will probably be the middle or end of September before this will be accomplished.

Quantities and Contractors.

The estimated quantities in the steel and wooden cribs were as follows:

	Crib.	
	Steel.	Wooden.
Pine timber, ft. B. M.	284,319	404,166
Hemlock timber	......	480,000
Oak timber	1,120	8,774
Pine lumber, rough, ft. B. M.	20,696	19,800
Pine lumber, planed and matched	11,600	15,500
Steel plates, angle beams, etc., lbs.	*2,861,288	......
Cast iron, lbs.	17,610	......
Drift bolts, lbs	14,314	54,695
Spikes	952	......
Screw bolts	11,426	14,250
Concrete, cu. yds	785	......
Stone filling, cords	2,640	1,390
Rip-rap, tons	3,000	5,500

*Including machine bolts.

The tunnel and four shafts will contain the following estimated quantities: Excavation, 95,515 cu. yds.; brick, 15,785,000; steel, 91,400 lbs.; cast iron, 549,000 lbs.

All the work was let to Cleveland contractors, as follows: Steel crib, the Van Dorn Iron Works, for $137,393; wooden crib No. 1, L. P. & J. A Smith, $50,000; wooden crib No. 2, T. H. Garland, $44,445; tunnel and shafts, W. J. Gawne, $524,190; total, $756,038. Mr. J. J. McReynolds has been associated with Mr. Gawne in the tunnel work and the Schailer & Schniglau Co., of Chicago, are carrying on the work from the two temporary cribs, including both shafts and the tunnel work extending therefrom, but the city recognizes Mr. Gawne only as connected with it.

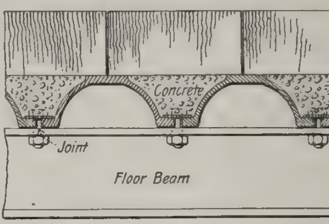
Up to July 22 progress at the three tunnel headings had been made as follows: 6,541 ft. had been completed from the shore shaft westerly; 1,392 ft. from temporary crib No. 1, easterly; and 1,429 ft. from the same crib westerly; making a total of 9,362 ft.

We are indebted to Mr. Kingsley for information and blue prints used in preparing this article, and also to the several contractors for courtesies extended to our representative. We are also indebted to both Mr. Kingsley and Mr. Schulz for a revision and several important additions to the article, especially with a view of noting changes and progress made since our representative visited the work. The additions by Mr. Schulz are properly accredited to him wherever inserted.

WOOD BLOCK PAVEMENT ON THE SUSPENSION BRIDGE OF AVIGNON, FRANCE.

M. Armand describes in the "Annales des Ponts et Chaussees," for the first quarter of 1898, the repaving with wooden blocks of the suspension bridge over the Rhone, at Avignon. This bridge is 743 ft. long, in three spans, and was built in 1843, and rebuilt and stiffened in 1887-89. The floor, however, was still made of wood, with transverse planks laid on longitudinal stringers; and with the extensive use of the bridge and the dryness of the climate this floor was constantly under repair, to the great annoyance of passengers over it.

It was determined to take advantage of the more rigid structure by laying a pavement of wooden blocks; but a solid foundation was requisite for this purpose, and the vibration of the bridge was liable to disintegrate concrete as ordinarily laid. At first, a floor of steel plates riveted to iron cross I-beams was suggested, and on this were to be laid the wooden blocks, imbedded in bitumen and the joints filled with cement. This type of pavement would have cost about $7.27 per sq. yd.; as based upon 38 francs per 100 kilos. for steel, and 14 francs per sq. meter for the wood pavement. But it was found difficult to put down this floor without interrupting the traffic, and for this and for other reasons a new plan was adopted in November, 1897, which permitted the use of beton.



Part Cross-Section of Floor of Avignon Suspension Bridge.

Stamped steel troughs were used, weighing 25 lbs. to the yard, and these were laid parallel to the axis of the bridge and bolted to the transverse floor beams, which were ordinary I-beams. A thin iron strip laid in the bottom of the trough formed by the meeting of two of the shapes tightly closed the space between them and served to hold the heads of the bolts. The cross-beams were spaced 4 ft. apart on centers. The space between the troughs was now filled with beton to the level of the top; upon this foundation were laid wooden blocks 8 ins. deep, with bitumen poured in the joints to a certain height and the joint then finished with cement mortar. This pavement was covered with fine gravel and opened to traffic 48 hours after its completion. The whole work was completed between Oct. 18 and Nov. 14, 1897.

The advantages gained are—the very considerable decrease in the cost of maintenance, the increased comfort to users of the bridge, and the removal of the danger of fire. The total cost of replacing the floor was $3,192; but the annual repair account was formerly $1,200, and the repairs to the present floor, including a fund to replace pavement when worn out, should not exceed $900 per annum.

STANDARD METHODS OF TESTING PAVING BRICK.*

By Arthur N. Talbot, M. Am. Soc. C. E.†

The extensive use of brick for street paving purposes in our interior cities has made the adoption of standard methods of testing paving brick a matter of interest alike to engineers and manufacturers. The present diversity of practice does not permit an accurate understanding of the requirements of any set of specifications.

To make a durable pavement, brick must have, to the requisite degree, toughness and hardness, strength, and imperviability to liquids. Acceptable methods of testing paving brick must be easy and convenient to make and must give similar results when repeated, and the apparatus must be easily and cheaply duplicated anywhere. Such tests must determine the qualities of the brick, must distinguish soft from hard, and brittle from tough, and must do justice to both large and small brick.

---

*Slightly condensed from "The Technograph," of the University of Illinois.

†Professor of Municipal and Sanitary Engineering, University of Illinois.

The test commonly used to determine toughness and hardness is known as the rattler test, or impact and abrasion test. Abrasion machines are unsatisfactory, because they do not include a test of the impact effect. The rattler test gives the impact and abrasion effect, but there is such a great variation in size of rattler, in speed and duration of test, and in the amount and kind of foundry shot used that the adoption of a uniform method and uniform conditions becomes a matter of great importance.

Two societies have had under consideration for three or four years the matter of standard tests of paving brick—the Illinois Society of Engineers and Surveyors and the National Brick Manufacturers' Association. The committee of the National Brick Manufacturers' Association, known as the Commission on Paving Brick Tests, made a very comprehensive set of tests and secured a large amount of valuable data.* Their work is certainly a valuable contribution to engineering literature. A recommendation of the Commission, adopted by the Association, was that the rattler test be made the principal test, and that it be made without foundry shot; i. e., with a charge of brick alone. Among the specifications adopted are the following: That the standard rattler shall be 28 ins. in diameter and 20 ins., long, but that machines having diameters between 26 and 30 ins. and lengths from 18 to 24 ins. may be used; that the cross section of the barrel shall be a regular polygon of from 12 to 16 sides; that the shaft shall not extend through the chamber; that the charge shall consist of a number of brick of one kind nearest equal in bulk to 15% of the bulk of the rattling chamber; that the per cent. of loss of weight be determined for 1,800 revolutions at a speed of 30 revs. per min.; and that the average of two distinct and complete tests made on separate charges of brick shall be used as the official result.

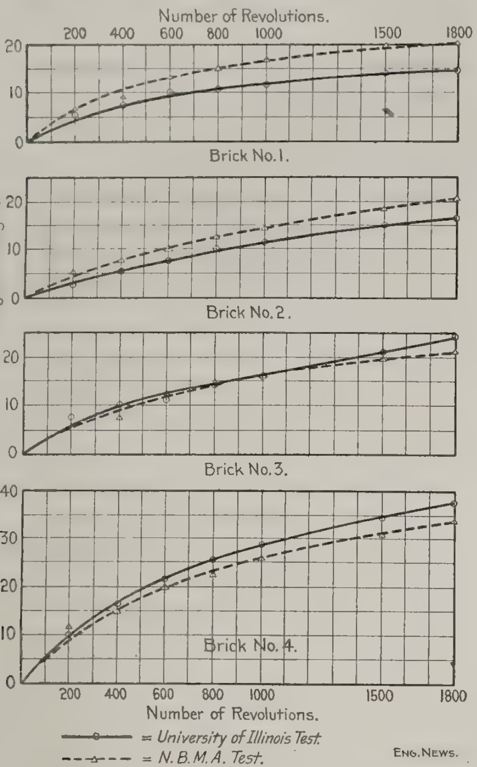


Fig. 1.—Rattler Losses of Paving Brick; Comparison of Results by Standard Methods of the University of Illinois and the National Brick Makers' Association.

By Prof. Arthur N. Talbot, Champaign, Ill.

The efforts of the Illinois Society of Engineers and Surveyors have been to secure the adoption of some standard form and amount of foundry shot which may easily be exactly duplicated and which will give the proper relation between the impact and the abrasion effect, in place of the miscellaneous foundry scrap so commonly used. Favorable consideration has been given to the shot used by the writer in the Laboratory of Applied Mechanics of the University of Illinois, in tests made for the Department of Public Works of Chicago, and known as the University of Illinois standard. This standard shot consists of cast-iron blocks of two sizes, a larger size, 2½ × 3⅛ × 5¼ ins., with edges rounded to ½-in. radius, weighing about 8 lbs. each, and a smaller size, 1 × 1½ × 2½ ins., with rounded edges, weighing about 1 lb. each. After experimenting with various mixtures, a mixture of even parts of large and small blocks was chosen. A large proportion of 8-lb. shot gives too great impact action and a smaller proportion gives too little. From 7 to 10% of the volume of the rattling chamber may be occupied by the shot. For the 24 × 36-in. rattler, 150 lbs. of 8-lb. shot and 150 lbs. of 1-lb. shot makes a good charge.

An advantage in the use of the iron mixture is that a few bricks or several may be tested without affecting the conditions materially. Thus, for the charge and size of rattler above mentioned, from 5 to 14 bricks may be tested at one time and the percentage of loss will remain nearly constant. This method easily distinguishes soft and brittle brick, and is fair to large as well as to small brick. The writer is of the opinion that the use of a standard amount of a standard form of cast-iron shot such as that used in the tests at the University of Illinois and mixed in such proportions as to give a proper relation between the impact and the abrasion action offers the best method of making the rattler test on the score of convenience, fairness, ease of securing standard material, detection of soft brick and measurement of toughness and ability to stand both impact and abrasion. The National Brick Manufacturers' Association Commission abandoned the use of cast-iron shot on the ground that the impact effect exceeded the abrasion effect; that the wear and tear on the rattler was prohibitory; and that the results did not give a good characteristic curve. It is to be regretted that this decision was reached on such a meager data and that a second form of foundry shot was not used. With the shot herein described, the abrasion effect is sufficiently marked, the wear on the machine is not excessive, and the characteristic curves are regular and uniform, as shown by the curves illustrated in this article.

However, the general adoption of a uniform method of testing paving brick is of such importance to engineers and manufacturers that the particular method selected is not essential, provided it fulfils the requirement of uniformity, fairness and thoroughness. If the National Brick Manufacturers' Association standard is satisfactory in these respects, the writer is quite willing to aid in securing its general adoption. The objections made to this method are that it requires a large number of brick for the test, too many to detect lack of uniformity if averages be taken; that a slight decrease in the number of brick below the number required to make 15% of the volume will seriously affect the results of the test; and that the method will not sufficiently distinguish soft and brittle brick. The last objection, if found to be true, would show a serious defect in the method.

To find whether the rattler test of the National Brick Manufacturers' Association does sufficiently distinguish differences in texture of brick known to be different in character, and also to compare the results of this method with those obtained with the standard cast-iron shot of the University of Illinois, a series of tests was made in the Laboratory of Applied Mechanics.

Four kinds of brick were used. Brick No. 1 was a repressed shale paver, 2½ × 3⅞ × 8⅛ ins., selected from the product of one of the best known manufactories, and an excellent brick. Brick No. 2 was also a repressed shale paver of excellent qualities, 2⅞ × 3⅞ × 9¼ ins. Brick No. 3 was a surface clay brick, well burned and a good article, 2⅛ × 3⅝ × 7⅝ ins. It may be said, however, that its structure, appearance and wear, and also its life in pavement under ordinary conditions, go to show that it is inferior to Bricks Nos. 1 and 2. Brick No. 4 may be ranked as a high-grade sewer brick or building brick, 2⅛ × 3⅞ × 7¾ ins. All were selected by the makers, and as the individual bricks were weighed during the tests, their uniformity is known from the data collected. The absorption test gave the following amounts in 48 hours, only rattled brick being used for the test: Brick No. 1, 0.5%; Brick No. 2, 2.2%; Brick No. 3, 3%; Brick No. 4, 4.7%.

The rattler used was the 24 × 36-in. rattler of the Laboratory of Applied Mechanics of the University of Illinois. A movable partition allowed this to be shortened to 18 ins. Although this diameter is 2 ins. less than the minimum allowed by the Manufacturers' recommendation, the variation will not affect the comparison in this discussion.

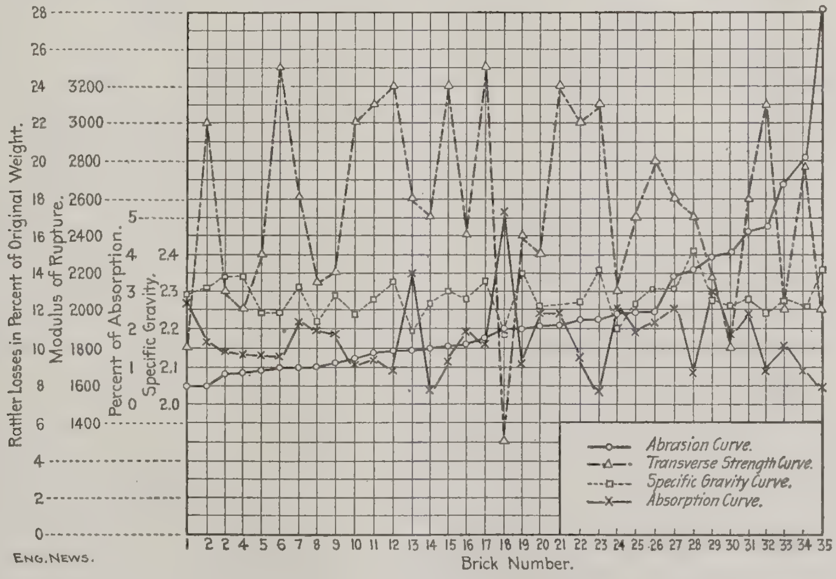

FIG. 3.—RESULTS OF TESTS OF 35 MAKES OF PAVING BRICKS.

Each make of brick was tested by the Manufacturers' test; i. e., without foundry shot and with a charge of brick equal in volume to 15% of the volume of the rattler. Experiments were made both with the full length rattler and with a length of 18 ins. The speed was about 30 revs. per min.

Each make of brick was also tested with the form of shot known as the University of Illinois standard cast-iron blocks. For the full rattler, 150 lbs. of the large and 150 lbs. of the small shot were used, and for the 18-in. length, one half of this amount. The speed was about 20 revs. per min. Twelve bricks were used in the full rattler and six in the half length.

The brick were weighed at the end of 200, 400, 600, 800, 1,000, 1,500 and 1,800 revolutions. The results have been plotted and are shown in the diagram, Fig. 1, the abscissas representing the number of revolutions and the ordinates the per cent. of loss in terms of the original weight. It will be noted that the curves, now generally called characteristic curves, are quite similar, and that the Manufacturers' curve is above the Illinois curve in Brick No. 1 and Brick No. 2, crosses it in Brick No. 3, and is below it in Brick No. 4. To make a comparison of the two methods, the diagram shown in Fig. 2 was constructed. The loss of Brick No. 1 was taken as unity, and the losses of the others were expressed in terms of this and plotted as shown.

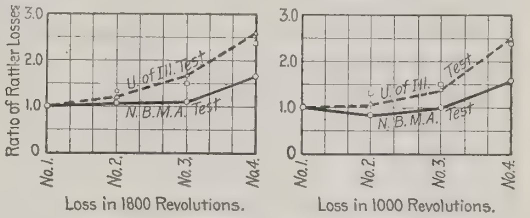

Fig. 2.—Ratio of Rattler Losses to Loss of Brick No. 1 Compared with Ratio of Reciprocals of the Moduli of Rupture.

The ratios of the reciprocals of the moduli of rupture of the different makes to that of Brick No. 1 are shown by the points enclosed in squares.

Two things may be seen from Fig. 2: (1) The Manufacturers' test makes Brick No. 3 as good as No. 1 and No. 2, when, as has been stated, it is manifestly inferior. (2) The loss in Brick No. 4, which is unfit for pavement, is much less distinctly marked in the Manufacturers' test than in the Illinois test.

If these conclusions are borne out with other makes of brick, the Manufacturers' test has serious defects. It does not sufficiently distinguish between hard and tough brick and soft and brittle brick. A satisfactory method of testing paving brick must show the difference between bricks of the nature of No. 1 and No. 2, and such as No. 3, and will make a more marked distinction between bricks like No. 4 and hard and tough bricks.

The ratios of the reciprocals of the moduli of rupture of the different makes to that of Brick No. 1 are shown in Fig. 2 by the points enclosed in squares. It will be seen that these ratios increase much as the ratios of rattler loss by the Illinois standard. The values of the moduli of rupture were the averages of five brick, and there was no great variation in individual cases.

The tests described above were verified partly by repetition and partly by comparison with results obtained with the same brick heretofore, and it is thought they are representative of the makes of brick used. It may be added that in the Manufacturers' test, a charge of soft brick soon broke, and thereafter the loss was much lighter. In general, the impact effect of the test was insufficient to test the toughness of the brick. The results are quite different from those anticipated by the writer.

---

*See Eng. News, May 6, 1897, for a very full abstract of this report, with editorial comments.—Ed.

While the tests described are not extensive enough to warrant rejecting the standard method of the National Brick Manufacturers' Association, they show that the method should not be adopted without further investigation. It is hoped that engineers having opportunities to make such tests will contribute to the general knowledge of the subject. If these results shall prove to be representative, the method of using a charge of brick alone cannot properly be adopted as a standard by engineers.

The recommendation of the National Brick Manufacturers' Association abandoning the absorption test and not recommending the cross-bending test will not be acceptable to engineers. It is true that the limit of absorption has frequently been placed too low, that overburned brick are as bad as underburned, and that uniformity of brick is more important than low absorption. With a moderately low limit, as 3 or 4%, and a definite time of say 48 hours, brick which pass the rattler requirement but which have high absorptive qualities would be cut out. The cross-bending test adds another precaution. The results are indicative of shearing and crushing strength—qualities which are necessary in a pavement having heavy traffic. It takes the place of the crushing test, which is difficult to make.

As a matter of interest on the topic of tests of paving brick, the diagram, Fig. 3, is presented. The data are from tests made in the Laboratory of Applied Mechanics of the University of Illinois, on thirty-five makes of paving brick from Ohio, Indiana, Illinois, Iowa and Missouri. They are plotted in the order of loss by the rattler test, the different properties of the same brick being shown on the same vertical line. These may be said to be picked brick, and among them are the best paving brick of the country. It will be seen that while there is a considerable variation in the modulus of rupture, in a general way the value decreases as the rattler loss increases.

THE SIMS-DUDLEY PNEUMATIC GUN.

The present war is affording an excellent opportunity to test in actual service the many new forms of weapons which have been brought forward during recent years. Some of these types are proving very successful; one in particular, the Sims-Dudley pneumatic gun, owing to its adoption by the Cuban insurgents, previous to the declaration of war, and later by the Rough Riders, has received considerable notice in the daily press. Generally it is spoken of as a dynamite gun, but it is really a pneumatic or compressed air gun throwing shells filled with high explosives.

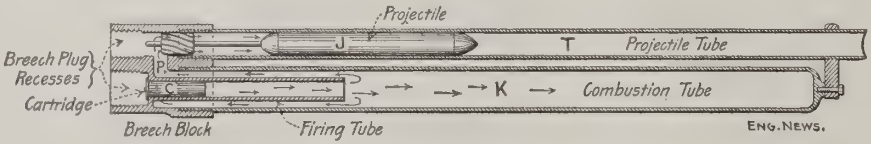

FIG. 2.—DIAGRAM ILLUSTRATING THE PRINCIPLE OF THE SIMS-DUDLEY PNEUMATIC GUN.

The accompanying cut, Fig. 1, represents the gun in its latest form, such as is now in use in Cuba. In Fig. 1 it is shown ready for firing. The extreme simplicity of the gun is apparent and is largely responsible for the good work it has already done. The upper or projectile tube is made of a combination metal having a tensile strength of about 75,000 lbs. per sq. in. and is about 14 ft. long, with a smooth bore about 2½ ins. in diameter. Just below is what is termed the combustion or firing tube, which is a strong steel tube 7 ft. long and 4½ ins. in diameter. The breech block is a steel casting into which the projectile and firing tubes are screwed. It has a suitable passage connecting the tubes and a swinging back upon which are mounted two segmental screw breech closing blocks. These are swung into place and locked by turning a lever much the same as with ordinary breech-loading ordnance. The tubes are mounted upon trunnions with a seator and hand wheel for elevating. The limber is built of sheet steel and angles, thus making a light and strong mounting.

The principle upon which the gun operates is to start the projectile without shock and to increase its velocity through the whole length of its passage through the long tube. This permits the use of shells containing high explosives. To fire the gun the breech block is unlocked by turning the hand lever, the cartridge, really a large blank shell, resembling a shot-gun shell, but about 6 or 7 ins. long, and containing 7 to 9 oz. of smokeless powder, is thrust into the shell chamber of the lower tube, Fig. 2. The projectile seen lying on the ground in Fig. 1 is then placed in the projectile tube, the breech closed and locked, and the gun is ready to be sighted and fired, which is done by pulling a lanyard in the ordinary way. This permits the firing pin, previously drawn back, to fly forward under the action of a spring and strike the fulminate cap of the cartridge. The large volume of gas immediately issuing from the cartridge C, Fig. 2, fills the combustion tube K, compressing the air contained. This air, now under considerable pressure, at once rushes through the passage in the breech block P and forces the projectile J out of the tube T. The powder charge is proportioned so that the pressure produced is sufficient to give the projectile a velocity which will insure an effective range while producing little noise or smoke. As the gun is at present constructed, the range varies from 2,600 to 3,600 yds.

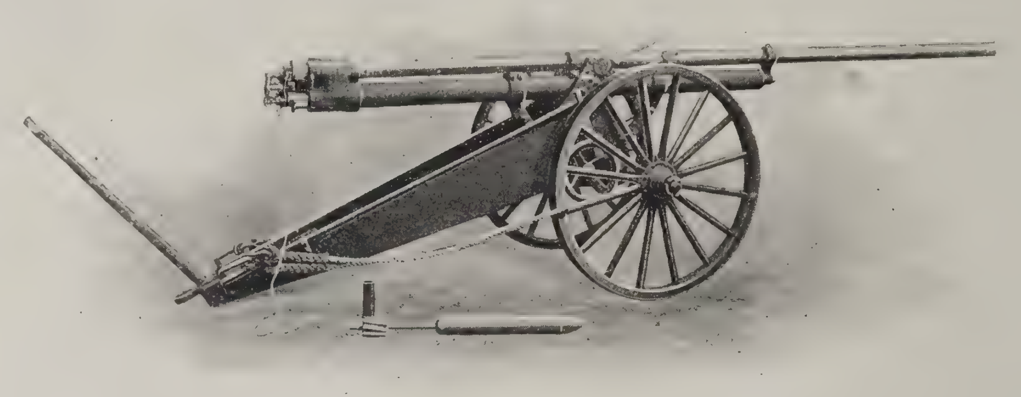

FIG. 1.—SIMS-DUDLEY PNEUMATIC GUN READY FOR USE, SHOWING PROJECTILE AND CARTRIDGE.

Sims-Dudley Defense Co., Makers, New York, N. Y.

The projectile, Fig. 3, is simply a light casing containing the explosive gelatine and the mechanical fuse, and is provided with an aluminum spiral on an extension at the rear end, which produces the rotation necessary to keep the projectile in a straight course. The main portion C, Fig. 3, is a thin brass tube 2½ ins. in diameter, containing the explosive charge, which so far has been what is known as Nobel's gelatine, a tough jelly-like mass containing nitro-glycerine and nitro-cotton, a mixture that does not explode as easily as dynamite but produces a much more destructive explosion; H is a conical brass head containing the time fuse which can be arranged to explode the charge after any given interval. This fuse ignites the fulminate of mercury in M, which explodes a small amount of gun-cotton in the metal case G, and the explosion of this sets off the main charge. To prevent accidental explosion in the gun or during transportation, the fuse head H is provided with a small wind vane and a screw, not shown in the illustration, which confines the firing device. After the projectile has left the gun, this vane whirls around, loosens the screw and falls off before it has traveled more than 200 ft. The complete projectile is 36 ins. long and weights when loaded 11½ lbs., the casing weighing 7½ lbs. and the charge 4 lbs.

It is possible, with a squad of about six men, to continually operate the gun at the rate of about five shots per minute, or 20 lbs. of the highest form of explosive known could thus be thrown each minute into the ranks of an advancing enemy without being seen or heard. The effect of the heavy explosions, each of which would be fully as destructive as a 6-in. shell can be imagined. The destructive effect of the explosive gelatine used is several times as great as that of the powder ordinarily used in shells, to fire which requires heavy artillery. In fact, such shells can only be used in siege operations, owing to the difficulty in transporting guns and ammunition.

The following table gives some further data in connection with these penumatic guns:

Dimensions, Weights, Range, Etc., of the 2½-in. Caliber Gun.

		Type of gun. Three-tube, light.	Type of gun. Two-tube, heavy.
Cartridge.			
Length		3 ins.	6 to 7 ins.
Amount of smokeless powder		3½ ozs.	7 " 9 ozs.
Gun.			
Weight	Gun alone	250 lbs.	480 lbs.
	Heaviest piece	150 "	310 "
	Carriage, complete	450 "	564 "
	Carriage wheels	120 "	150 "
	Gun complete, on carriage	700 "	1,044 "
	Naval mount	400 "	400 "
	Gun complete, on naval mount	650 "	880 "
Length	Projectile tube in gun	9 ft.	13½ ft.
	Gun,* on carriage, over all	12 "	16 "
	Gun,* naval m'nt, " "	10 "	14 "
Range of gun in yds.		1,750	2,600†

*Gun complete. †2,600 to 3,600 yds.

TRANSFORMER LOSSES AND THEIR DETERMINATION.*

By Frederick Bedell, M. Am. Inst. E. E.†

The condition very nearly attained in the operation of a transformer is the transference of power from the primary to the secondary without loss, a raising or lowering of the voltage in the ratio of the secondary turns (S_2) to the primary turns (S_1), and a corresponding decrease or increase in the current in the ratio of S_1 to S_2. As an example, let $S_1 = 10\ S_2$ in a 20-K-W. transformer. The condition nearly attained is

Primary watts = 20,000 Secondary watts = 20,000
" volts = 1,000 " volts = 100
" amperes = 20 " amperes = 200

In reality we have in the secondary an amount less than the above, as 19,200 watts, 98 volts, 196 amperes.

We accordingly have the following losses:

Lost watts; lost volts; lost amperes. The first determines the efficiency; the second, the regulation; the third, determines the magnetizing current.

The lost watts are due to hysteresis, eddy currents, and copper losses both primary and secondary.

The lost volts are due to copper drop (which is proportional to copper loss) and reactance drop due to magnetic leakage.

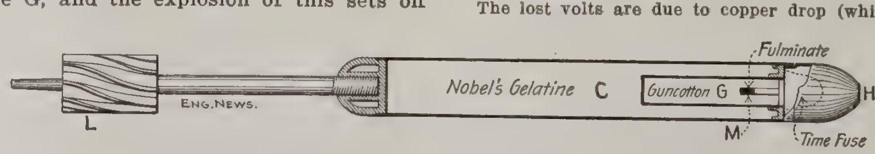

FIG. 3.—DIAGRAM SECTION OF EXPLOSIVE PROJECTILE.

The lost amperes (magnetizing current) consists of two components, $I\mu$ the exciting component which takes no power, and an energy component I_h at right angles to it.

The hysteresis loss in watts is

$$\text{Vol. } \eta\ n\ B^{1.6}\ 10^{-7};$$

---

*Read before the Electrical Society, Cornell University, Ithaca, N. Y., May 4, 1898, and printed in the Sibley Journal of Engineering.

†Assistant Professor of Physics, Cornell University, Ithaca, N. Y.

where the volume is in cu. cms., n is the number of cycles per second, and B the number of C. G. S. lines per sq. cm. The hysteresis coefficient η varies with the grade of iron, being about 0.002 for good iron. This and the following formula are due to Steinmetz.

The eddy current loss in watts is

$$\text{Vol. } \gamma \, (d\ n\ B)^2\ 10^{-21};$$

where d is the thickness of laminations expressed in mils. The eddy current coefficent γ is the conductance of the iron (the reciprocal of the resistance in ohms per cu. cm.) and is about equal to 10^5. In this case, eddy loss in watts equals

$$\text{Vol. } (d\ n\ B)^2\ 10^{-16}.$$

It is not possible to calculate the eddy current loss with a high degree of accuracy; this, however, is not essential inasmuch as it is but a small part of the total loss.

If R_1 I_1 and E_1 are the resistance the current and the electromotive force of the primary, and R_2 I_2 and E_2 the resistance, current and electromotive force of the secondary, the copper drop in per cent. is

$$\frac{R_1\ I_1}{E_1} + \frac{R_2\ I_2}{E_2}.$$

In lighting transformers of the best makes this constitutes almost all the voltage drop, the reactance drop being comparatively ineffective.

The two components of the magnetizing current are

$$\text{Power component, } I_h = \text{watts core loss} \div E_1.$$

$$\text{Exciting component, } I\mu = .707\ \frac{10}{4\ \pi}\ \frac{B\ l}{S_1 \mu}.$$

Here l is the length of the magnetc circuit in cms.; μ is the permeability and has a value of about 2,000. The total magnetizing current is

$$I_0 = \sqrt{I_h^2 + I\mu^2}.$$

The formulæ given above may be used for calculating the lost watts, volts and amperes.

In transformer testing, the magnetizing current and the core loss (including both hysteresis and eddy currents) are found by ammeter and wattmeter measurements made on the low potential coil at normal voltage, the high potential coil being on open circuit.

Measurements with wattmeter and voltmeter on the high potential coil with normal current, the low potential coil being short-circuited, give directly the copper loss and impedance drop. The copper loss divided by the current gives copper drop. The reactance drop is

$$\sqrt{(\text{impedance drop})^2 - (\text{copper drop})^2}.$$

If we let x be per cent. reactance drop and $i\mu$ per cent. exciting current, we have for lighting transformers:

$$\text{Effective reactance drop} = 100 - \sqrt{10{,}000 - x^2 - 2\ x\ i\ \mu}.$$

The total drip or "regulation" is the sum of the copper drop and the effective reactance drop.

For power transformers, if $\cos \theta$ represents the power factor of the load:

$$\text{Effective reactance drop} = 100 - \sqrt{10{,}000 - x^2 - 200\ x \sin \theta}.$$

To determine the eddy current loss in watts, the core loss must be measured at two frequencies. Let W′ be total core loss at normal voltage E′, and frequency n′. At a lower frequency n″ and a lower voltage

$$E'' = \frac{n''}{n'}\ E',$$

let the core loss be W″. We may compute the watts eddy current loss at the highest frequency (n′) and normal voltage by the formula

$$\text{Watts eddy currents} = \frac{W' - \dfrac{n'}{n''}\ W''}{I - \dfrac{n''}{n'}}.$$

If the electromotive-force wave at the two frequencies is essentially different, this may be taken into account as follows: Let the form factor (f) be the ratio (see Bedell's "The Principles of the Transformer," p. 312 et seq.) of the average to the virtual value. (For a sine wave this is .9). The core loss W″ at the lower frequency is to be measured at a voltage

$$E'' = \frac{n''\ f'}{n'\ f''}\ E'.$$

The eddy current loss in watts at the higher frequency n′ and normal voltage is

$$\frac{\dfrac{n''}{n'}\ W' - W''}{\dfrac{n''}{n'} - \left\{\dfrac{E''}{E'}\right\}^2}$$

This formula is exact; neglecting the difference in shape of the electromotive force-waves (i. e., assuming f′ = f″), this reduces to the formula first given.

The efficiencies may be computed quickly and accurately by the following table (devised as a time-saver), in which c_2 is the copper loss at full load expressed as per cent. of output, h_2 is core loss as per cent. of full load output, and t is time:

Fraction of load.	Losses as per cent. of output. Copper.	Core.	Total, t.	$\frac{t^2}{100}$	Efficiency.
5/4	5/4 c_2 = ...	4/5 h_2 = ...	....	....	....
1	c_2 = ...	h_2 = ...	....	....	....
¾	¾ c_2 = ...	4/3 h_2 = ...	....	....	....
½	½ c_2 = ...	2 h_2 = ...	....	....	....
¼	¼ c_2 = ...	4 h_2 = ...	....	....	....
1/10	1/10 c_2 = ...	10 h_2 = ...	....	....	....

$$\text{Efficiency} = 100 + \frac{t^2}{100} - t.$$

The all-day efficiency, assuming that the transformer is on full load for x hours each day and idle the remainder of the time, is

$$\text{All day efficiency} = \frac{100}{100 + c_2 + \dfrac{24}{x}\ h_2}.$$

This method for computing efficiency, and also the formula for the experimental determination of eddy current losses and for effective reactance drop in lighting and power transformers are here given for the first time.

(The following example, also by Dr. Bedell, will illustrate the use of the foregoing.—Ed.)

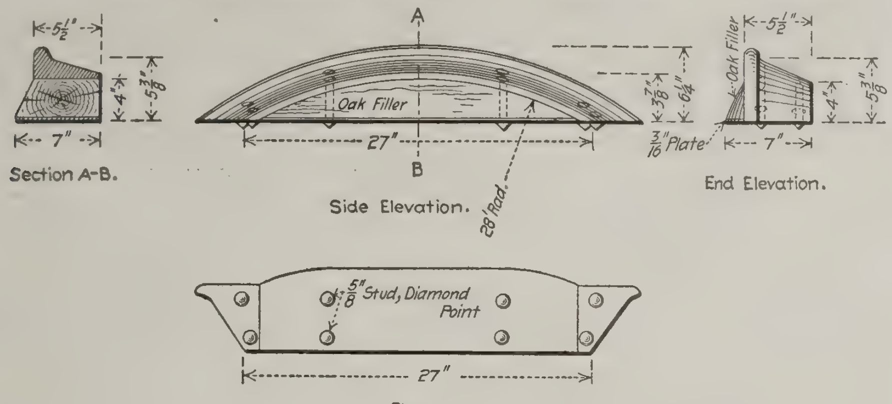
2-K-W. transformer. Copper loss = 48 watts. Core loss = 30 watts.

$$c_2 = 2.4. \quad h_2 = 1.5.$$

Fraction of load.	Losses as per cent. of output. Copper.	Core.	Total, t.	$\frac{t^2}{100}$	Efficiency.
5/4	5/4 c_2 = 3.0	4/5 h_2 = 1.2	4.2	0.18	95.98
1	c_2 = 2.4	h_2 = 1.5	3.9	.15	96.25
¾	¾ c_2 = 1.8	4/3 h_2 = 2.0	3.8	.14	96.34
½	½ c_2 = 1.2	2 h_2 = 3.0	4.2	.18	95.98
¼	¼ c_2 = .6	4 h_2 = 6.0	6.6	.44	93.84
1/10	1/10 c_2 = .24	10 h_2 = 15.	15.24	2.32	87.08

$$\text{Efficiency} = 100 + \frac{t^2}{100} - t.$$

$$\text{All-day efficiency} = \frac{100}{100 + c_2 + 4.8\ h_2} = 91.24.$$



THE "BURLINGTON" CAR AND ENGINE REPLACER.
Henry Miller, Asst. Supt., C., B. & K. C. Ry., Inventor.

A NEW RERAILING DEVICE.

Car replacers or wrecking frogs, for replacing derailed car and engine wheels upon the track, form a somewhat important feature of the minor part of railway equipment, and a great variety of these devices are in use. The accompanying illustration represents the replacer which has been adopted as the standard rerailing device of the Burlington railway system, the special feature of which is that it is very simple in design and is made from scrap at the railway shops.

It consists mainly of a segment of the discarded tire of a locomotive driving wheel, the tread being beveled and the flange turned down to some extent. The space under this piece of tire is filled in with a wooden block, the bottom of which is protected by an iron plate 7 ins. wide, made of 3-16-in. scrap tank iron. The plate, block and tire are secured together by eight ⅝-in. steel rivets, which have countersunk heads in the tire, and diamond points projecting ¾-in. below the plate. These points act as spurs to prevent the replacer from slipping when in use. The smaller size is 27 ins. long, 5⅜ ins. high over the tread, and 6¼ ins. over the flange. The larger size is 32 ins. long, and 6⅜ to 7¼ ins. high.

This device is styled the "Burlington" replacer, and is the invention of Mr. Henry Miller, of Hannibal, Mo., who is Assistant Superintendent of the St. L., K. & N. W. R. R., and the C., B. & K. C. Ry. (Burlington system). We are indebted to Mr. Miller for a blue print and description of this rerailer.

A BELGIAN GAS-LEAK DETECTOR.

U. S. Consul Morris, of Ghent, describes a method in use in that city for detecting gas-leaks, which he describes as follows in the "Consular Reports," for June, 1898:

> The outfit consist of a large hand drill or auger, several hollow tubes or pipes of the requisite length, a few corks fitted with quills through the center, a bottle of or-palladium, and a few bits of white paper. The tubes must be long enough to enter the ground to a point about 15 to 20 ins. above the main and to project above the street pavement a sufficient distance for observation, say 3 to 4 ft. They may be iron, such as common interior gas pipe, or, better still, brass, which is lighter to carry and more convenient to handle.
>
> Several paving blocks are first removed for a space of about two yards immediately over the gas main, and holes are bored in the soil with the drill, care being taken to thoroughly loosen the earth and extract as much as possible. In each of these holes a piece of the hollow piping is planted. It should not be rammed down too deep, so as to be too near or below the gas main, or to become clogged with dirt. On the upper exposed end one of the corks is placed, with the quill in the center, running up and down parallel to the pipe. A small piece of the white paper is dipped in the or-palladium and pushed into the open quill. Twenty or thirty such detectors are put in position at one time. If a leak exists within, say, two yards of any of them, the effect of the escaping gas will be evident upon the paper, rendered sensitive by the reagent, and it will at once turn black. The effect of the action of the gas upon the detector first placed in position will be evident before the last one of a row of 20 is set up. It is a common sight to see two or three men in the streets of Ghent making experiments in this manner for the detection of leaks. Indeed, the gas company causes regular tests to be made in turn in all the streets of the city. The loss by leakage is now said not to exceed more than 3%.

LEGAL DECISIONS OF INTEREST TO ENGINEERS.

Steam Rollers Not a Street Obstruction.

A steam roller, while being properly used in repairing a street, is not such an obstruction or defect in the street as will render the city liable for injuries inflicted by a horse frightened by such machine. Lane v. City of Lewiston (Me.), 39 Atlantic Rep., 999.

Electric Light Plant Not a Public Necessity.

Under the laws of North Carolina prohibiting municipalities from contracting debts or laying taxes, except for necessary expenses, unless by a majority vote of the qualified voters, such city having general powers only, cannot issue bonds for the erection of an electric light plant for lighting its streets, as such plant is not a "necessary expense," without legislative authority to submit the proposition to the voters and a ratification by a majority of such voters. Mayo v. Town of Washington (N. C.), 29 Southeastern Rep., 343.

Freight Rates and State Laws.

A state enactment, or regulations made under authority thereof, establishing rates of transportation by the railroad, that will not admit of the carrier earning such compensation as, under all the circumstances, is just to it and to the public, would deprive such carrier of its property without due process of law, and deny to it the equal protection of the laws, and would therefore be repugnant to the Constitution of the United States. Smyth v. Ames (Sup. Ct. U. S.), 18 S. C. Rep., 418.

When Objections to Improvements are Too Late.

After street improvements are completed, a landowner cannot object to assessments for the same on the ground that the contract was let to one whose bid was slightly more than that of another; although the law requires the contract to be let to the "best bidder." City of Bloomington v. Phelps (Ind.), 49 Northeastern Rep., 581.

Liability for Making Gas Connections.

Where a gas company insisted upon making all gas connections, between house mains and pipes, and assumed that duty, it was bound to exercise due care in performing it. A provision on the back of an application to furnish one with gas, exempting the company from damages from an explosion from the use of gas has no application where the explosion was caused by the imperfect closing of the gas main by the employees of the company when no gas was being used in the house. Bastian v. Keystone Gas Co. (N. Y.), 50 N. Y. Supp. Rep., 537.

Contractor Bound by Certificate.

Under a contract providing for compensation at a fixed price per cubic yard of earth moved, the amount due to be certified by the general manager of the railroad company month by month, such certificate is conclusive, in the absence of fraud, mistake or gross carelessness, to prevent the contractor after completing the work from asserting a claim for extra compensation for alleged overhauls. Breyman v. Ann Arbor R. Co. (U. S. Cir. Ct.), 85 Federal Rep., 579.

BOSTON OFFICE, 299 DEVONSHIRE ST.

SUBSCRIPTION RATES: United States, Canada and Mexico, One Year, $5.00; 6 months, $2.50; 2 months, $1.00. To all other countries in the Postal Union: Regular Edition, One Year, $7.60 (31 shillings); Thin Paper Edition, One Year, $6.31 (26 shillings). SINGLE COPIES of any number in current year, 15 cents.

Mailing addresses may be changed at will by sending both old and new address. The number on the address label of each paper indicates when subscription expires, the last figure indicating the year and the one or two preceding figures the week of that year; for instance, the number 328 means that subscription is paid to the 32d week (that is the issue of Aug. 11) of the year 1898; the change of these figures is the only receipt sent, unless by special request.

ADVERTISING RATES: 20 cents per line. Want notices, special rates, see page 18. Rates for standing advertisements sent on request Changes in standing advertisements must be received by Monday afternoon; new advertisements, Tuesday afternoon; transient advertisements by Wednesday noon.

It seems that, after all, Spain has given unwilling, but very convincing testimony as to the manner in which the battleship "Maine" was destroyed in Havana harbor. At the time of that catastrophe Spanish officials loudly insisted that the cause was an internal explosion of one or more magazines, the result of "carelessness and a notorious lack of discipline on the American ships." But the board of officers appointed to report upon the result of our gun-fire upon the ships of Admiral Cervera, sunk in the Santiago fight, incidentally find a valuable object lesson in the appearance of these ships that has a direct bearing upon the destruction of the "Maine." Three of the four Spanish warships were blown up by their own magazines, and one of them had every magazine exploded, with all its torpedoes in addition. But as compared with the wreck of the "Maine," there was no upheaval of the keel and little bulging of the plates except in the immediate vicinity of the point of impact; the effect of the explosion was nearly always upward, the protective deck was sometimes lifted, but, except for the springing of a few plates, the hulls were intact. In other words, the evidence gathered from the wrecks of these Spanish warships, that in armor and guns were practically superior to the "Maine," conclusively shows that the latter ship was sunk by an external explosion, however brought about.

◆

Another most valuable object lesson afforded by these ships is the terribly destructive effect of the smaller projectiles of the secondary batteries, as handled by American sailors. The fight started at a range of 6,000 yds., and narrowed down to about 1,000 yds. at the closest point. But one ship, the "Infanta Maria Theresa," was struck by 12-in. or 13-in. shot, and only two of these landed on the ill-fated warship. The "Christobal Colon," which kept out of range most of the time, was struck six times by 8, 6 and 5-in. projectiles; the "Vizcaya," with 10 and 12-in. armor, was hit with larger projectiles fourteen times, and by 6-pdrs. eleven times; the "Infanta Maria Theresa," as before mentioned, was pierced twice by 12 or 13-in. shot, and by one 8-in. shell; but the "Almirante Oquendo," of the same class as the last two, was hit four times by 8-in. shell, three times by 4-in. and twice by 6-in. projectiles, and 42 times by 6-pdrs. But in all cases, except the "Colon," it was the fire of the secondary batteries that wrought the greatest havoc and practically destroyed them. By this fire the decks were swept and men were driven from the guns; the explosion of shells fired the ships, and on the "Theresa" cut the water-mains, so that the fire could not be extinguished. The structure above the armor belts was torn into shreds; and though it cannot now be definitely determined whether fire on board or shells exploded the torpedoes, and some of the magazines, it is evident that the deadly rain of small shells kept the Spaniards from working their guns or from taking measures to preserve themselves and their ships from fire. The moral of this sea-fight is that modern ships and modern guns are only really formidable when the men that handle the ships and guns are not only brave, but also skilled in the use of these war-tools. What would happen when the antagonists are equally balanced in these qualities can better be guessed at than described.

◆

Three of the Spanish warships were practically destroyed by fire started by the explosion of American shells, and the wisdom of reducing to a minimum the woodwork aboard our vessels and fireproofing that which must be used becomes apparent. Eight of the gunboats authorized in 1893 and 1895, were fitted with wood made fireproof by a simple and satisfactory process, which consisted in withdrawing all sap and moisture from the wood, in a vacuum, and then filling the pores with phosphate of ammonia. Wood so treated will only char and will not shrink, but objection was made that such wood was heavier, and not quite as strong as untreated wood, and that it was difficult to work and had a tendency to absorb and retain moisture. It was also complained that paint did not stick to it very well and the contained chemicals had a corrosive effect upon metal in contact, and spoiled the clothes of officers contained in drawers made of it. These are serious charges, and in January of this year a board of naval officers, convened for the purpose of reporting upon fireproof wood, voted in favor of discontinuing its use. But Naval Constructor Hichborn, who made a minority report in favor of wood thus treated, says that the greater number of these charges are false. Fireproofed wood is used in many of the costly large buildings now being erected, and there is little trouble in working or painting it; and for ships' use, especially in decks, its non-shrinking qualities are invaluable. Its increased weight is of comparatively little importance, and the additional cost adds but a few thousands of dollars to the millions invested in a battleship. The terrible experience in the Santiago fight, added to the almost forgotten destruction by fire of the Chinese ships in the Yalu River combat, have brought about a decided revision of the finding of the late board, in this connection, and the order has already gone out so to protect at least the wooden decks of the new battleships. The lesson taught at Santiago is that fire and smoke will drive the bravest men from their guns and make impossible any efficient defense against hostile attack. In other words, if modern ships and guns are to be successfully employed against modern gun-fire, it is of the greatest importance that all internal fittings be made fireproof. If there are any valid objections against present processes of fireproofing Yankee inventive skill should eliminate them.

◆

THE INVESTIGATION OF THE NEW YORK STATE CANALS.

The report of the Commission appointed by Gov. Frank S. Black to investigate the work done upon the New York State canals under the $9,000,000 appropriation, which is abstracted elsewhere in this issue, is a document which does credit to its authors. The predictions that the Commission would present a "white-washing" report, for the sake of the political and commercial interests involved, have not been fulfilled. The arraignment by the Commission of those responsible for the loss of over a million dollars to the State of New York is temperate and judicial in its tone, but the facts are set forth with a fearless straightforwardness that is most convincing.

Let us briefly sum up the story of the New York canal improvement, as it is told in the Commission's report:

The State Engineer's estimate of its cost given to the Constitutional Convention in 1894 was $11,573,000, and was "little more than a guess." This was cut down to $9,000,000 by the advocates of canal improvement, apparently for no better reason than the fear that this was as large a sum as the people of the state could be induced to approve by a popular vote. It was hoped that by omitting all work not absolutely necessary, this sum might suffice. When it came to making plans and specifications, however, there seems to have been absolutely no attempt to "cut the cast according to the cloth." The plans were made exactly as if an unlimited sum were available, and works were planned and carried out which had nothing whatever to do with the deepening of the canals.

The sums expended thus far may be divided as follows:

Advertising for proposals		$92,321
Superintendent's Inspectors	$178,969	
Engineering	812,000	
Total for engineering and inspection..		$990,969
Paid to and due contractors		7,937,903

Of these amounts, the Commission finds that at least $80,000 was improperly expended for advertising. The inspection carried on under the Superintendent of Public Works appears to have been needlessly extravagant; $41,514 was paid to the force of inspectors during the ceven months of open navigation in 1897, when work on the contracts was practically at a standstill. During the present year $98,922 has been paid to inspectors appointed without civil service examinations, and apparently for other reasons than their ability and fitness.

Of the engineering expenses, $272,000 was for preliminary surveys, on the basis of which the estimates and bidding sheets were made up and contracts were let, and this work the Commission finds to have been necessary. The survey did not accomplish, however, what it should have. No study was bestowed on special conditions, and the contracts were let without provision for meeting these conditions. Contract 4 on the Middle Division (the Jordan level) is an example. The contract price, according to the engineer's estimate, was $154,471; but up to May 1, 1898, it had cost $581,879.

Of the $272,000 for preliminary surveys named above, $50,391 is for plans for a pneumatic lift lock at Lockport, and special improvements at Cohoes, which were unwarranted and improper.

Turning now to the total of $7,937,903 represented by work done on the contracts, the Commission finds that not less than $1,000,000 has been improperly expended. The contractors have benefited through the improper classification of earth as rock; through the making of unbalanced bids for work, through unwarranted payments for material overhauled, in which case embankment price was added to excavation price. "More than half of the total amount of cost of embankment was improperly paid for material overhauled and wasted"; and finally, through allowances for "extra work." Up to June 1, the engineers had returned $824,821 as extra work; but the actual quantity is much greater. Besides the above, it is stated that $30,810 was spent in Syracuse, on work which had nothing to do with canal deepening, and elaborate plans ware made for expending $100,000 to benefit the milling interests at Lockport.

As one reads the instances of extravagance and illegal expenditure set forth in detail in the Commission's report, the conclusion is inevitable that their estimate of $1,000,000 as the amount which the contractors have received in excess of their just dues, is a conservative figure. When the unnecessary expenditures on advertising, engineering and inspection are also taken into account, it seems probable that the total sum of which the state has been robbed will reach a million and a-half or more, or about one-sixth of the total amount which the taxpayers of the state borrowed for the purpose of deepening the canals. The most hardened defender of the old-time maxim that "to the victor belongs the spoils," must agree that so great a proportion of "pickings and stealings" cannot be justified.

UNIVERSITY OF ILLINOIS

The action of the Governor in calling upon the legal authorities to take steps for the immediate prosecution of those responsible for the misappropriation of public funds and the misuse of public trusts deserves the warm approbation of all good citizens. It is just such corruption of public office for private gain as this investigation has laid bare that has brought the once great Spanish nation to the depths of humiliation and defeat. The American people must effectually punish such exhibitions of official corruption and malfeasance as the Canal Commission has uncovered, if they would preserve their own nation from a decay and degeneration similar to that which has eaten out the vitality of Spain.

We have it on excellent authority that one of the men who was seeking to reap a rich harvest from the canal fund, but who found the way blocked by an honest and incorruptible public official of high rank, swore with a great oath that he would give five thousand dollars to get this faithful guardian of the public treasury into the North Woods; and would guarantee that he would never be seen again alive. Surely, when matters have come to this pass it is time the people of the state should arouse themselves to the dangers that menace their government. No political influence, no considerations of personal favor should stand in the way of the detection, conviction and punishment of those who have robbed the state or been false to their trust.

We have thus far heartily commended the Commission's report; but when we turn to its recommendations as to the future work upon the canals, we are obliged to take issue with it. While the Commission was made up of non-partisans from a political standpoint, it was made up of men who are without exception known as "canal men," and it advises the completion of the canal improvement with no question whatever as to whether the work will be worth what it will cost in the benefit of commerce. Instead, the Commission brings forward the well-worn old fallacy that because the canals in the days of their prosperity paid into the state treasury a large amount above their cost, the state should not hesitate to pay out for their improvement the whole of this surplus. Not one of the able business men composing the Commission conducts his private business on such a principle. If a machine becomes obsolete in type, no longer able to produce goods in competition with newer and more modern devices, it never pays to make extensive repairs upon it, unless it appears that after these repairs are made, it will be able to compete with other machines and return to the owner a profit on the amount spent.

The conviction is growing upon all intelligent students of transportation economics that all such barge canals as those of New York state are obsolete machines; and that no such small improvement as that which the state has now undertaken can restore to them their traffic and prevent their abandonment in the early future. The Commission estimates that $15,616,000 additional will be needed to complete the deepening of the canals to the extent contemplated by the law of 1895; but how is that fund to be obtained? The people of New York who were assured three years ago that $9,000,000 would do a certain piece of work are now told, after they have furnished this sum, that about two and one-half times as much will be required! Are they likely to throw good money after bad? Because they have borrowed nine millions, and dropped one or two of them into dishonest pockets and the rest into the mud of the canals, is no sign that they will consent to borrow fifteen or sixteen millions more to meet a similar fate.

Further, for more than two years to come, there is no way in which New York can obtain further sums for canal improvement, except by direct appropriation by the legislature from funds in the treasury. It is now too late to submit a proposal for the issue of bonds to popular approval at the election next November. In November, 1899, certain constitutional amendments have to be voted upon and no bond proposal can be submitted to the people. Thus it will not be before November, 1900, that any proposition to issue further bonds for canal improvements can be submitted to the people. But by that time the falling off in canal traffic is likely to reach such proportions that the dullest cannot fail to comprehend that the day of the old barge canal is past.

Freight cars of 60,000 to 100,000 lbs. capacity hauled by modern powerful locomotives, are cheaper and more efficient machines for handling freight.

By 1900, moreover, the project for deep waterways from the Great Lakes to the Atlantic, on which the United States is now spending nearly a half-million in preliminary surveys, will probably have taken such shape that we shall at least know something of the cost of such new avenues for traffic, and whether their construction would be a paying venture. It goes without saying that if any such work is to be carried out, all money expended on permantnt improvements on the Erie Canal is practically thrown away. It may be said with truth that the chances are very small that the Government will undertake so vast a work as a ship canal from the Lakes to tidewater promises to be. The possibility, however, is bound to have more or less influence on public opinion; and there is also the possibility that in place of the ship canal the Government may take up the more modest, but much more promising project for a barge canal of large size over the Erie Canal route.

Taking all these conditions into consideration, the chances that the people of New York can be persuaded to approve the expenditure of some $16,000,000 more upon the canal deepening seems to us extremely remote. We are aware that the influences which favor the canal appropriations are very strong. The political leaders of both parties see large opportunities in them for strengthening whichever party happens to be in power. The commercial interests favor the canals, from force of habit. It has so long been dinned into people's ears that the canals are an essential factor in the commercial prominence of New York, Buffalo and the cities along the line of the canals throughout the state, that people have come to accept it without question. Time, however, will change all these influences. The politicians are likely, in the next two years, to learn more of the real temper of the people concerning the canal improvements. Those who defend the commercial importance of the canals are becoming wiser as the canal commerce dwindles, and New York's cities continue to flourish and grow. It seems to us very unlikely, therefore, that the recommendation of the Commission for the further improvement of New York's canals will ever be carried out.

LETTERS TO THE EDITOR.

Temperature and Sensible Heat.

Sir: As your editor who wrote the answer to Mr. Gould's letter in to-day's issue seems to be a little hazy on the generally accepted meaning of sensible heat, it might be well for him to look the matter up in standard works on thermodynamics. He can find the term as used by Rontgen in Du Bois's translation of his Thermodynamics, ed. 1880, bottom p. 379; and its relation to the temperature in the equation at the top of page 376. L. F. R.

Philadelphia, Pa., July 28, 1898.

(The writer of the review of Mr. Gould's book does not admit that he is hazy on the meaning of the term "sensible heat," but confesses that he is somewhat surprised to find the extent to which the inaccuracy of using this term to mean "heat of the liquid" has crept into the literature of thermodynamics. It is a good example of the too common practice of scientific writers to take a term from the ordinary language of the people and give to it a new and restricted meaning. Mr. Gould's book, p. 9, says "Temperature and sensible heat are generally considered as synonymous terms." Why should they not be? "Sensible" means perceptible by the senses, and heat that is perceptible by the senses is what is commonly called temperature. The temperature of water at the boiling point is 212° F. This is its sensible heat. The heat units in 1 lb., measured above 0°, are 212.9 B. T. U. The 0.9 B. T. U. excess of this "heat of the liquid" above the figure representing the temperature is not "sensible," and therefore it is inaccurate to call the 212.9 B. T. U. sensible heat. Heat of the liquid is a much better name for it. —Ed.)

Spacing Stiffeners in Plate Girders.

Sir: I notice in your issues of May 19, June 9 and July 7 letters on the subject of "Spacing Stiffeners in Plate Girders," and an allusion to my paper read before the American Society of Civil Engineers in 1885, on "Specifications for Iron Bridges." History repeats itself, and Mr. Beach seems to have worked out the problem on much the same lines as I did myself. So far as the question of I-beams or girders without stiffeners is concerned, there appears to be no dispute.

When I went to Altoona on the Pennsylvania R. R. in 1860, fresh from the Rensselaer Polytechnic Institute, I found in use on that road plate girder bridges, 50 and 60 ft. long, or longer, and 4 to 5 ft. deep, having only 3-16-in. webs, with vertical stiffeners of cast iron, placed on each side and bolted together through the web by three bolts, these being the only connection. The stiffeners hugged well up under the flanges of the girder and were spaced at intervals equal the depth of the girder, more or less. These bridges were, without question, the best and stiffest type of structure on the road, were considered in every way the most reliable, and were carrying with safety any load that could, with the then existing rolling stock, be placed upon them. Some of them may be still in use on branch roads.

When, however, I came to design such structures and applied Rankine's rule for vertical web, "considering that the shearing stress at the neutral axis is equivalent to a pull and a thrust of equal intensity, inclined opposite ways at 45°, and that the vertical web tends to give way by bucking under the thrust," I found to my surprise that these bridges ought to have been utter failures, and, according to Rankine, should have doubled up and departed this life.

The matter gave me considerable study, in the course of which I made a model of a girder with a thin paper web, something similar to the one I send you, only larger, and I found at once that the web did not resist by compression and give way by buckling, but by tension. I made diagonal slits in the web, as you see in this model, converging downwards towards the center. These being in the line of tension did not affect the strength in any way, as you may see by placing this model on supports at the ends, with the proper flange, as marked, up, and applying a heavy weight. When, however, I reversed the girder, with the other flange up, making these slits or cuts converge upward towards the center and placing the web in a condition that it could not resist by tension, the absolute weakness of the girder was at once apparent, and if much load were placed on it, it would break down, the web buckling up under compression. It was upon this practical solution of the problem that I formed my theory of the computation of web and stiffeners, which I stated in my paper, and which for thin webs I still maintain. If one will only give the matter a few moments thought and develop the plate girder from the open truss by increasing certain members to an infinite number, the result ought to be self-evident.

If there are no stiffeners, Rankine's rule holds good and the case is one of a lattice girder with an infinite number of lattice pieces forming a continuous web. Stiffeners in girders could, of course, be placed inclined instead of vertical, except for practical convenience in construction.

The increased thickness of web adopted in later years has not been due to theory but entirely to practical considerations, principally that of deterioration and rusting of the metal in thin sheets from the action of the coal-smoke of engines, and also to increase the bearing surface for rivets. Webs riveted in between angles have, of course, a great resistance merely from the hold which the angles have on them like the jaws of a vise, and in the early days there was not as much attention paid to the bearing surface of rivets as now. Shearing was the only matter considered. In those early days, also, engines burned wood, and coal-smoke with its sulphur fumes did not exist in any quantity.

When one comes to the use of a thick web and proposes to use it for all it is worth, the problem naturally becomes more complicated. A certain portion may be included in the flanges of the girder and often is by those economically inclined; perhaps a portion with the stiffeners; and then, if thick enough, it may also resist by compression as well as by tension, approximating to a girder without stiffeners. For my own part, I would prefer to make my calculations on the theory I have indicated, and having obtained the minimum dimensions for parts, then increase them as practical considerations from my experience, questions of wear and tear, etc., would make advisable.

Yours very truly,
Jos. M. Wilson, M. Am. Soc. C E.

Philadelphia, Pa., July 19, 1898.

(The general appearance of the model sent by Mr. Wilson is shown quite clearly in the accompanying engravings made from photographs taken in the office of Engineering News. These photographs show the model girder loaded in the two ways suggested by Mr. Wilson. Fig. 1 is a view of the model placed with the slits in the web converging downward and loaded with a block of type metal, weighing 1¼ lbs. It will be noticed that the slits are drawn tight and that the web between each pair of stiffeners is tight and smooth. With the same load placed on the opposite flange of the model; that is, with the slits converging upward, the appearance is as shown by Fig. 2. In this view it will be seen that the slits are sprung apart and that the web is buckled between the stiffeners its entire length. The action of the girder with the two methods of loading described corresponds to the description given in Mr. Wilson's letter, and is a remarkably graphic and convincing proof of his statements.—Ed.)

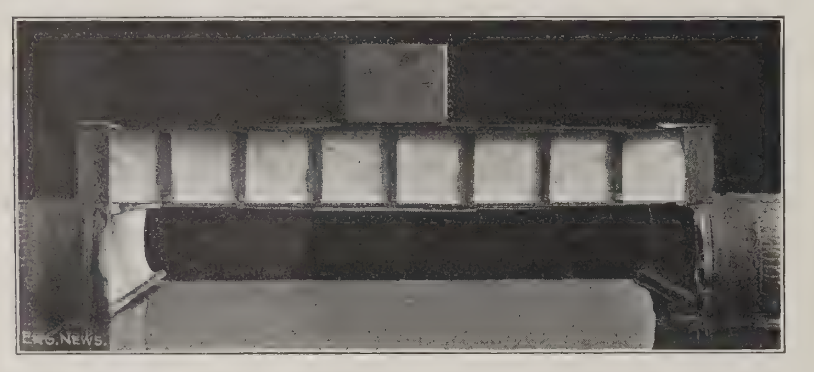

FIG. 1.—VIEW SHOWING EFFECT OF 1½-LB. WEIGHT ON MODEL GIRDER WITH SLITS IN WEB IN THE LINES OF TENSION.

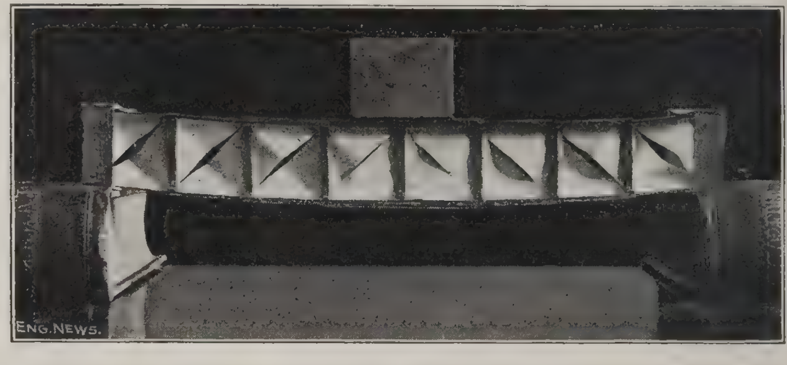

FIG. 2.—VIEW SHOWING EFFECT OF 1½-LB. WEIGHT ON MODEL GIRDER WITH SLITS IN WEB CONTRARY TO THE LINES OF TENSION.

Sir: Permit me to make a few, somewhat belated, comments on a communication in your issue of July 7th. "Practical Bridge Builder" is pleased to take me to task for what he considers a violation of the ethics of criticism, in my failing to point out more explicitly wherein a previous correspondent has erred in his so-called "theory" for the spacing of stiffeners, but, instead, contenting myself by calling attention to a few easily accessible references on the subject.

While I quite agree with this second writer in that, generally speaking, "the burden of proof rests upon the critic," I must submit, that the critic, in this instance, is none other than the original author, on whose side he has seen fit to arraign himself. From what the former terms a "theory;" but what must be regarded a conjecture, pure and simple, unless proved otherwise; he has ventured to draw conclusions, utterly at variance with certain incontrovertible principles of mechanics, without adducing a single argument in their support. It requires but little familiarity with the subject to recognize that each and every one of his six conclusions is untenable. But until something tangible is presented in their support, it is not worth the time or space to enter upon a detailed discussion to prove that the assumed analogy between a plate girder and a Pratt truss cannot possibly exist.

Unless "Practical Bridge Builder" can himself offer something more substantial in behalf of the Pratt truss "theory," than the account of his observations on the behavior of the web at the end of a certain plate girder, his views, too, will fail to impress sensibly on a thoughtful reader. What he has cited in that connection would go equally far towards proving a plate girder bridge similar to a Fink truss, a Bollman truss, or in fact any number of equally remarkable analogies. As a critic of what is generally regarded as sound theory, let him take to heart his own counsel.

Though seemingly superfluous, it may not be amiss to state that, before attempting to prove the analogy of a plate girder to any other form of construction, it is incumbent upon the critic—whether theorist or self-styled "practical" man—either to submit a formal refutation of the generally accepted theory of the distribution of stress in web plates, or to show that his own theory is merely an extension of the same. Nothing less than this can reasonably be expected to carry conviction, or is, in fact, deserving of serious consideration.

Passing over certain inaccuracies in my critics reference to my former communication, which are patent to anyone, I have only to defend myself against the carelessly thrown out charge, that in my reference to the spacing indicated in the sketch accompanying the original communication, I have presumed to state, or even to intimate, that your correspondent's guess was wrong, because slightly different from my own. That what I did write does not admit of this absurd construction will be shown to any reader who can recognize the broad distinction between a matter of empiricism (in the sense of experience, not experiment), and a matter of guess.

To sum up, experience in the case of hundreds, probably thousands of girders, has shown that if the stiffeners are placed at intervals not exceeding the unsupported depth (inside of flange angles) of the web, security against buckling is assured, provided that the bearing requirements of flange rivets are fully met. Toward the ends of a girder, the intervals are frequently reduced in a purely arbitrary fashion. That this is not necessary is attested by the record of the numerous girders designed after Cooper's specifications, which embody no such requirement. It goes without saying, that for girders of very great depth, the rule named must be modified in the case of thin webs, according to individual judgment, to ensure their better alinement. The proper size of stiffeners can be computed only at the supports. The sizes of the intermediate ones are absolutely beyond the reach of theory.

With apologies for trespassing on your space to this extent, in a matter that can have but little interest to the general reader, I am

Very respectfully, E. M.

Philadelphia, Pa., July 23, 1898.

◆

Notes of an Engineer in Colorado.

Sir: The readers of Engineering News may be interested in a brief description of what the writer saw in a recent trip through the principal towns of Colorado. I entered the state from the north, traveling over the Union Pacific Ry. to Denver, thence over the Denver & Rio Grande standard-gage line to Grand Junction, and from there over the Rio Grande Western through Utah to my home at Salt Lake City.

From Cheyenne, Wyo., southward for about 40 miles there is no industry or agriculture but stock raising. Between Pierce and Eaton the first irrigated lands are reached, and thence all the way to Denver one has an ocular demonstration of the benefits of irrigation.

Greeley, 54 miles from Cheyenne and 52 miles from Denver, was the birthplace of the art of irrigation for the English-speaking people of Colorado. The town was laid out in 1870 by a colony under the fostering care of Horace Greeley. With but little experience in farming, and none in irrigation, these colonists went to work with a will, and, despite many failures at first, they have succeeded in establishing a colony that is pointed to as a model by many that are interested in irrigation. The Cache a La Poudre River, a fine stream from the mountains, runs through the town, and supplies most of the irrigation canals.

I took a run from Greeley up to Ft. Collins, 25 miles to the northwest. Besides being in a rich farming section this town is the site of the State Agricultural College. I met here Prof. L. G. Carpenter, professor of civil and irrigation engineering, and was shown what his department was doing in instructing, not only the students, but the public at large, through the experimental work at the Agricultural Experimental Station.

Prof. Carpenter has been stationed at the college for ten years, and his researches and writings have caused him to become well known abroad as well as in this country, wherever an interest is taken in irrigation. For the 300 to 350 students per year coming to the Agricultural College, there are four courses of four years each open. The only degree given for any of the courses is that of Bachelor of Science, though special degrees are given for post-graduate work. Over one-half of all the graduates are from the engineering course. Male students in all the courses devote one-third of their sophomore year to surveying, with field practice in compass and level work. Naturally a large amount of time in the civil engineering course is given to irrigation.

The civil engineering department has a building to itself. On the first floor are the office and library of the professor of engineering, the drafting room and also a room for carrying on the work of the irrigation engineering section of the Agricultural Experimental Station. This station is intimately connected with and under the same governing board as the college. In the basement are the physical and hydraulic laboratories. The hydraulic laboratory has tanks and a set of suspended scales, weighing to 5,000 lbs., for ascertaining very closely the amount of water flowing through orifices and over weirs.

The Department has Colorado, Lallie and Fteley current meters, the latter with an electrical recording attachment, and also a long-distance, electrical, self-recording water-level instrument, made by Richard Freres of Paris, by which the change in elevation of a water surface miles away in the mountains is recorded at the station.

As meteorology is an important factor in irrigation, instruction in this is given also, and a complete set of instruments, many of them imported, is in daily use. This includes self-recording thermometers, barometers, psychrometers, anemometers, pluviometers, actinometers, statoscope, soil thermometers, evaporation tanks, etc.

The Mechanical Engineering Department of the college has a large two-story building of its own, which is completely equipped for instruction and for manual training.

Denver.—This city has one of the best systems of street railways in the country, considering the great extent of territory covered. The total value of all the lines is about $4,000,000. The Denver City Railway Co. was the pioneer in street car matters, and its first horse car lines were built over 20 years ago. In 1889 most of the main lines were changed to the cable system. This was just before electric roads were proved to be a commercial success, and many hundreds of thousands of dollars in first cost, as well as excessive expenses in operation, could have been saved if electrical propulsion had been perfected a year or two earlier. The company has 30 miles of cable tracks (15 miles of double tracks) operated by six different cables running out of its power house at 18th and Lawrence Sts. The longest of these cables is the West Laramie, 32,000 ft. long. The plant at the power house has about 1,600 HP., while about 85 cars are run and 350 men employed. Though much inferior to the electric lines in economy and service, the cable line plant here represents a high type of engineering skill. More miles of cable railway are probably operated from this power station than any other single one in the world. A brief account of the plant and tests of its efficiency by the constructing engineer was given in Engineering News of Aug. 17, 1893, p. 130.

The company's system was sold under foreclosure after the panic of 1893-4 for $500,000. Something like $3,000,000 had been invested in it. An application to the city council for a franchise allowing the cable system to be changed to electrical has been made, but has not yet been acted upon. The Providence girder rail, 6 ins. high and 56 lbs. to the yard, was used in the cable road for convenience in paving, and it will be difficult to use it again if the cable yokes are taken up, as the base is so narrow that the outside jaw of the yoke is relied on to brace it. Even if the present track is used, the heavy electric cars of the present day (weighing two or three times as much as the cable cars) will be likely to test the girder rail very severely.

The company also owns the West End Electric Road, having 10 miles of track, 10 cars, a power house of 1,000 HP., and employing about 30 men. This is about the only standard-gage street railway in Denver—the others being 3½-ft. gage. The company also operates 4¾ miles of its old-time horse lines. On the cable road the cars run 11,000 car miles daily, on the electric 1,000, and on the horse track 175. The total number of passengers carried during 1897, including the transfers, was 9,000,000, and the car mileage was 2,000,000 miles.

The Denver Consolidated Tramway Co., now much the largest of the street railway companies, is an interesting example of the results of energy and good management. The Denver Tramway Co. was organized in 1888 to build a cable railway system. Franchises were secured and construction proceeded with that year, notwithstanding the vigorous opposition of the pioneer company, which had before had a monopoly of street railway privileges. All the money was furnished by local capitalists.

The cable system included 18 miles of track, costing about $40,000 per mile. The company soon decided that electric roads were the best, and all the additions have been of that system. In 1893 the 18 miles of cable line were converted into electric road, the cable conduit, etc., being left in. It is stated that about $25,000 per mile would have been saved if electrical propulsion had been so perfected as to allow of it at the start. The power house was built at the corner of Broadway and Colfax Ave., the center of the system and in the then resident district, and was a large building with handsome exterior. Cotton ropes were used in the place of cog gearing, on account of the objections to noise in this locality. The building has been abandoned, and the machinery used for other purposes where possible. The system as now consolidated includes 58½ miles of track in double track, 36 miles of single track and 4½ miles of sidings, etc., or 99 miles in all. It operates about 75 cars daily, and 18,000,000 passengers were carried in the first 10 months of 1897. It is found that there is a saving of about 6 cts. per car mile over the cable road, notwithstanding the great increase in the size of the cars, and as to freedom from stoppage, flexibility under very great variations of traffic and general convenience, the electric roads are found to be decidedly the best.

The old cable cars weighed 6,500 lbs., and carried 40 passengers; the new electric cars with motors weigh 16,000 lbs., and hold 100. Both the General Electric and the Westinghouse systems of electricity and motors are used, the latter ranging from 10 to 35 HP. The company has lately begun tearing up its old cable tracks to replace them with rails on ties. In forming the cable conduit the bottom part only was made of concrete, the sides being of plank stretching from yoke to yoke. On account of this, which was looked on as a penny-wise method at the time, the loss will be much less than if the entire conduit had been of concrete, as in the Denver City and other cable roads. The boards are considerably rotted, but still serviceable at the end of ten years. The yokes are broken off in pieces by sledge-hammers and used as old iron, the part imbedded in the concrete being allowed to remain. In the new track in the paving districts "T" rails 6 ins. high and weighing 72 lbs. are used. 30-ft. lengths rolled at Pueblo were first used, but more lately 62-ft. lengths, coming from the Johnson Co., Lorain, O., have been used. About five miles of the track had been replaced with heavy rails up to May of this year. Creosoted ties, 6 x 8 x 6, coming from the Michigan Pipe Works, at Bay City, Mich., and costing 94 cts. each, delivered, are used. The Servis tie-plate has also been adopted. The old cable road rails are only 35 lbs. weight. In the paving district all street car companies have to pave between the rails and for 2 ft. each side. This company spent about $80,000 in 1897 on such work, much of it re-paving.

In addition to the roads named, the Colfax Electric Railway has 11 miles of single track (east of the city limits); the Denver, Lakewood & Golden Ry. Co. has nearly 4 miles of electric road in the city, and the 34th Ave. line has 1½ miles of track, which are operated in one direction by horse-power and on the return by gravity—carrying the horse. There are altogether about 155 miles of street railway track in the city and suburbs.

In good weather nearly all of Denver's streets are in good condition, but before paving began in 1890 the business streets were miserable in very wet weather. There have been over 14 miles of pavement laid, all but about 16% being asphalt. The sandstone paving is confined to the down-town district.

Denver's sewer system has also nearly all been built since 1890, and is now quite complete, containing 224 miles of sewers.

Denver has become a very important manufacturing center during the past few years, and as the cost of living is now as low as in the East, one of the most important factors in the relative cost of manufacturing in the West is thus eliminated. Iron works, and especially works for the manufacture of machinery used in mining, milling and smelting, have a very extensive trade in the mountain regions. The manufacturing district lies principally along the Platte River, for a distance of about 9 miles. The Omaha & Grant, the Globe and the Boston & Colorado smelters, all at the north end of this district, give employment to nearly 1,500 men. In this locality are also the great Jersey shops of the Union Pacific Ry. Co, leased on May 1 to the Union Pacific, Denver & Gulf. Besides its own work, the U. P., D. & G. does a great deal of custom work at these shops, including much for the Union Pacific.

At present only about 230 men are employed in the machine and engine shops and 150 in the car building department here. The track for a heavy electric crane was provided in constructing the machine shop, but this was never put in (thus saving about $5,000), and instead airlifts of about two tons capacity are used. These prove to be more rapid and to make a great saving of time in handling all small pieces. A 15-HP. Thompson-Houston motor is used for operating the transfer table, and by having call signals provided for the operator at one corner of the building he is not required to be at the table all day, but gets in three or four hours' work at a lathe.

The roundhouse was formerly lighted by electricity, but it was found that the stationary lights were not at all suited for inspecting the parts of an engine, and if carried around for this purpose many were broken. They were taken out and the regular engineer's oil lamp is now used, with 8 large oil bracket lamps placed around the walls for general lighting. By this means $300 per month is saved, two electric light dynamos and an engine being left idle. The omission of the overhead crane left room at one end of the overhead tramway to fit up a tool room.

Three steel viaducts connect the main part of the city with that west of the So. Platte River, crossing over the numerous railroad tracks along the river bottoms. Two of these, on 16th St. and on West Larimer St., were built by the Denver City Cable Ry. Co. The first of these is about 3,000 ft. long, the last considerably more. The 14th St. viaduct, now being built by the city, will be about 3,500 ft. long.

In the engineering profession I found that business had been extremely quiet for several years past—beginning with the panic of 1893—but that it has lately been picking up. Many engineers who had their own offices during the better days gave them up, and either attempted working on a salary or else moved to other parts of the state or the country.

Prices of living, merchandise, etc., have come down in Denver the past few years, until it now more nearly resembles an Eastern city than any other in the West; and with penny papers and other evidences of Yankee economy it must make the old-timer who returns here feel somewhat pensive when he remembers the scorn with which anything less than 10 to 25 cts. was formerly regarded.

All municipal improvements in Denver are built under charge of the Board of Public Works, the engineering staff making the surveys, as well as plans for new structures. The duties of the city engineer's office are mostly confined to street and lot lines and grades.

The state engineer's office is a very important one in Colorado, having control not only of irrigation, but of many state public works. Mr. John E. Fields is the present incumbent. For the administration of the irrigation laws, the state is divided into six natural drainage divisions, each in charge of a superintendent, and these into 69 districts, each in charge of a commissioner. All the streams of the state used for irrigation are regularly gaged. There are many volunteer observers of gages, but some are paid about $5 per month. The state engineer's department carries this along in conjunction with the hydrographic department of the U. S. Geological Survey, the former paying the salaries and the latter the expenses. One deputy is in the field all the time, making the rounds of the principal gaging stations about once a month. The last legislature made no appropriation for public works such as have been constructed under supervision of this department, but it is likely that the next one will provide for further expenditures. W. P. H.

Salt Lake City, Utah, July 1, 1898.

THE NEW YORK STATE CANAL INQUIRY.

In March last Gov. Black appointed a special commission to investigate and report upon the work already done in enlarging and improving the Erie, Champlain and Oswego canals, in the State of New York, under the provisions of Chapter 79 of the Laws of 1895; whether the contracts were properly made and whether the money paid out was properly expended; the proportion of work done and that still to be done; and the amount of money in excess of the appropriation of $9,000,000 still required to complete the proposed enlargement and improvement. The commission submitted its report to the Governor on July 30, and though the detailed evidence is not yet accessible a brief summary of the report proper is here given.

The commission secured the services of Mr. Abel E. Blackmar, of New York, as counsel, and appointed Mr. Edward P. North, Vice-President American Society of Civil Engineers, as consulting engineer, and Mr. Lyman E. Cooley, of Chicago, as advisory engineer. The report commences with a brief sketch of the Erie canal system and makes the following statement of the actual condition of the work on the several canals at the present date:

Location.		Work, miles.		
		Completed.	Incomplete.	Not contracted.
Erie Canal	Eastern Division..	26.56	27.99	51.687
	Middle Division ..	23.18	73.61	None.
	Western Division..	3.45	112.40	31.81
	Total	53.19	214.00	83.497
Champlain Canal		5.886	24.03	36.11
Oswego Canal		6.63	6.73	24.11
Grand total		65.706	244.76	141.017

The commission notes that it is impossible to give the exact condition of the work done under these contracts, though its engineers report that the quality of the work performed is generally good and is an improvement upon that usually done upon our canals. As to the features of the work, the conditions as they developed were most unfavorable, and required a high degree of skill and moral strength to meet them; the pressure for haste resulted in demoralized and disorganized execution, and influences hereditary in canal work had to be combatted. As a general thing the contract prices were reasonable and as low as could be expected; there was actual competition between the bidders, and in a great many of the contracts there is nothing to condemn. The actual amount of money expended for the enlargement and improvement of the canals to July 28, 1898, was as follows:

Disinfectants	$6,684.93
Advertising	92,320.70
Inspectors	178,969.43
Engineering expenses	812,000.00
Paid to contractors	7,106,722.77
Continuing work on suspended contract No. 3	35,555.19
Total	$8,233,253.02

Under the law of 1895 not less than 10% of the amount due the contractor is to be retained by the state until the completion of the work, and including unpaid drafts amounting to $35,092.37, the apparent free balance out of the $9,000,000 appropriated is only $25,556.25. The item of disinfectants refers to the treatment of certain sewage-contaminated material excavated in the City of Buffalo.

In regard to advertising, the report states that the total amount thus expended upon the first 32 contracts was $74,978.50, an average of $2,343.08 for each contract. No attention was paid to the amount involved in the contract, and in one case the cost of advertising was 23% of the engineer's estimate of the total cost of the work, while in another case this cost was as low as one-third of one per cent. of the engineer's estimate. In later advertisements the superintendent's requirements were omitted and several contracts were grouped in one advertisement with the result that 49 contracts were advertised for $17,342.20, or an average of $353.92 each. The commission concludes from the evidence submitted that an average expenditure of $150 each would have properly advertised these contracts, and that $80,170.70 was improperly expended in this direction.

The report shows that while $38,532.80 was paid to inspectors during the season of closed navigation, and when work was being done, the sum of $41,514.19 was expended in paying these officials during the season of open navigation when work on the contracts had substantially ceased. The commission is of the opinion that a portion of the expense of maintaining this force of inspectors during the open season was useless, and therefore improper.

As no sufficient data existed in the engineer's office for the making of the estimates, maps, plans and specifications required by law, an expensive preliminary survey was absolutely necessary, and the commission deemed this expenditure requisite and proper. But a sum amounting to $49,391.32 was charged to these surveys and actually paid to experts for plans, etc., of lift locks at Lockport and Cohoes. While the employment of skilled and special engineering assistance is deemed generally proper, in such cases, the commission finds that the improvement contemplated by them was unauthorized and could not be legally made under Chapter 19 of the Laws of 1895, and this large expense was therefore improper. It was also deemed unnecessary to obtain complete working plans of three separate devices before choosing between them. The nature of the work required a large expenditure for engineerig services; but the complexity of the specifications, say engineers North and Cooley, has unnecessarily increased this cost.

For the purpose of making the contracts the canal was divided into contract sections, varying in length from .67 to 22.07 miles. The contractor bid upon the quantities estimated by the engineers, and upon the specifications, maps and plans accompanying the quantity sheets. In comparing bids these quantities were multiplied by the prices submitted, and the lowest total obtained the contract. If the quantity sheet does not represent with reasonable accuracy the actual amount of work to be done; or if the specifications admit of uncertainty of classification between the several items; or if the plans are indefinite, or made in the alternative; this method affords an opportunity for excessive final cost, unbalanced bids, improper classification and other abuses. The commission finds that, notwithstanding the large amount expended on the preliminary surveys, the quantity sheets, plans and specifications lack accuracy and definiteness. So far, the actual cost of the work let has exceeded the contract price by 9.84%; and the total cost of the work for which contracts have been let, including the estimated cost of those incomplete, will exceed the contract price by 69.08%. As early as July, 1896, it was evident to the State Engineer and to the Superintendent of Public Works that the cost of the work, as shown by the notes and measurements of the engineers, would far exceed $9,000,000. An attempt was then made to reduce the estimates by cutting out everything that did not seem to them to be absolutely necessary to obtain the result primarily aimed at in the statute. But this mutilation of the quantity sheets did not render the work unnecessary, and as the improvement progressed much of the work cut out reappears in an increase of quantities over the preliminary estimates. For example, the slope wall estimated for and bid upon amounted to 543,779 cu. yds.; while up to May 1, 1898, 425,916 cu. yds. of such wall had been built and it was then estimated that 432,839 cu. yds. more would be required to complete these contracts. The preliminary estimate of vertical wall was 106,353 cu. yds.; on June 1, 1898, 168,735 cu. yds. of this wall had been built, and the revised estimate called for 110,326 cu. yds. to complete the contracts.

The value of the preliminary estimates was also greatly impaired by the fact that they were made without reference to the specifications, and were in fact made before there were any specifications. The assistant engineers classified and defined rock and earth as each saw fit in making the original soundings and estimates, and the quantity sheets were prepared accordingly. When the specifications were afterwards made these terms, rock and earth, were given a technical and arbitrary meaning, and no revision of quantities was or could be made owing to lack of sufficient data. The specifications classed as rock, hard-pan which "could not be plowed," and the meaning of the term "embankment" was also changed in the specifications after the computation of quantities in the preliminary surveys. The following table shows a comparison of quantities as shown on the bidding sheets with the quantities of work actually performed:

	Cu. yds.
Rock in quantity sheets	550,183
Allowed to contractors to May 1, 1898.	740,068
Estimated amount to be excavated, May 1.......	253,501
Embankment in quantity sheets	729,374
Allowed to contractors to May 1	1,167,849
Estimated amount remaining, May 1.	615,145

This disparity is partly due to improper classification; and another source of error was inexcusable carelessness in omitting quantities actually returned and inserting a nominal small quantity of 70 or 100 cu. yds. into the bidding sheets; in another case 5,000 cu. yds., estimated, was set down as 500 cu. yds. The report deals at length with the discrepancies in excavation, which showed an excess of from 10.77 to 35.09% over the preliminary estimates. On contracts in the cities of Utica and Syracuse the improvement was made by both lowering the bottom and raising the banks, and here the preliminary estimates were 1,532,370 cu. yds., while the work actually done and that estimated to complete calls for 2,171,724 cu. yds., an increase of 41.72%. On these contracts the material was procured from outside the prism, during the navigation season, and before there was any excavation from the canal. All this material was taken from borrow pits and paid for as excavation; and that hauled over 1,000 ft. was paid for as embankment in addition. The reason given for this course was that the material in the prism was an unknown quantity; could not be used in winter as it was frozen, and the silt could not be separated from the harder material. The commission disagrees with this position and believes that the course pursued was a wasteful departure from the original intent of the contract and specifications which called for the use of proper excavated material upon the banks. On some sections there were extravagant returns made for mucking, or removing all vegetable matter to the depth of 6 ins. on the outside slopes of embankments.

The earth and rock classification, as before mentioned, was very faulty, both for the reasons already given and because the specifications confided this classification to the three resident engineers, who in this case had supervision over about 152 miles of canal. Personal examination in all cases was absolutely impossible, and anything like accurate work would have required more engineers. The average of all accepted bids for dry excavation of earth was 28.8 cts. per cu. yd.; the average for all accepted bids for dry excavation of rock was $1.42 per cu. yd. The report then takes up the three divisions separately, and by individual cases shows a great uncertainty and frequent and arbitrary reclassification of earth and rock. Space available forbids going into this interesting detail, and the same may be said for the detail of the embankment returns.

Under the head of extra, or additional work, we find that to June 1, 1898, work valued at $824,820.88 was done under special agreement, outside of the contracts, showing the insufficiency of the preliminary investigation. A large amount of this work was not contemplated by either party and was thus not within the contract itself. Some of this extra work, though admitted as useful and necessary, was paid for as excavation, slope wall, etc., under the contract prices, and only swells the quantities under the contract and does not appear in the work done by special agreement. "Extra work" was also largely done from force account with 10% added for profit to the contractor; and many claims exist for work done without special directions. Other work was performed which was not properly part of the improvement prescribed by law, and in some cases a free gift of material belonging to the state was improperly made to the contractors. In concluding their report the commission expresses the opinion that not less than $1,000,000 in all was improperly expended in the manner here pointed out.

In its estimate of total cost of the work, done and to be done, the commission submits the following statement:

Expended on contracts (approximately).....	$7,867,924.36
To be expended to complete contracts	4,731,600.00
Total	$12,599,524.36
Estimated for work to be let	8,900,000.00
Total cost of completed work	$21,499,524.36

In other words, 36.6% only of the entire work is finished. The $13,651,000 estimated to complete the work does not include engineering, and 10% should be added thereto. This estimate does include, however, the pneumatic locks at Cohoes and Lockport, the change of line at Newark and the improvement at Little Falls. But the commission does not recommend the pneumatic lifts at Lockport and Cohoes, and if the locks at these points are left as at present, the estimate would be decreased by $2,100,000. The engineers, Messrs. North and Cooley, with the approval of the commission, recommend certain changes in the location of the canal, which, if sanctioned by the legislature, would further diminish the estimated cost of completion.

It is only just to the State Engineer's Department to say that the estimates of 1896, based upon the preliminary surveys, put the cost of the improvement at at least $13,500,000, not including engineering, advertising or inspection. This estimate was improperly cut down to $9,000,000 to meet seeming demands, and upon this revision the work was let. As the work progressed it became evident that the official estimate was too small and another was made amounting to about $16,000,000. The State Superintendent of Public Works also committed the grievous error of letting contracts after it was apparent that the money remaining available was totally insufficient to complete these contracts. This has left long stretches of the canal in an incomplete condition and has involved the state in serious questions of liability to contractors.

The commission finds that the force allowed the State Engineer is not adequate to the performance of all the duties of his department. The State Engineer himself is a member of various boards and has many duties to perform outside of canal improvement. The present dual system in the management of canal affairs is also objectionable and is inherently vicious. It throws the responsibility upon two departments, those of the State Engineer and Surveyor and the Superintendent of Public Works, which have separate functions to perform, but are so interwoven as to make it extremely difficult to fix responsibility in case of negligence or wrongdoing. The commission recommends that the authority and responsibility be vested in one department, and that either the Superintendent of Public Works be given power to maintain a sufficient engineering force and take all the responsibility; or, that the State Engineer be intrusted with the business management of the canals and the entire responsibility of maintenance, repair and improvement. The last suggestion would involve the abolition of the Department of Public Works; and the first would duplicate the engineering force to a great extent and largely increase the cost. In any event, before further work is done there should be a more accurate study of the conditions, a revision of the specifications and the preparation of adequate quantity sheets for all work still to be performed. In conclusion, the commission recommends the continuation of the improvement on the lines contemplated to final completion, with such changes as have been suggested and that may be sanctioned by the legislature.

The entire cost of Erie canal system, up to 1895, is $102,345,123. The state has received from these canals, up to 1882, when tolls were abolished, $134,648,900; and these canals have thus much more than repaid the entire cost of construction, maintenance and repairs, up to Oct. 1, 1885. The report is dated at Albany, N. Y., on July 30, 1898, and is signed by the following commissioners: George Clinton, Chairman; Franklin Edson, Secretary; Smith M. Weed, Darwin R. James, Frank Brainard, A. Foster Higgins and William McEchron, Commissioners.

SEISMIC AND OCEANIC NOISES.

In the April issue of the "Monthly Weather Review," Mr. Samuel W. Kain, of the Natural History Society of St. John, N. B., and others, write of the mysterious "booming" noises often heard at sea and near the coasts. These sounds seem to be frequent off the coast of Nova Scotia; they resemble the distant boom of cannon, and they alarm and drive away schools of fish. Sometimes, as at Gannet Rock light-house, the sound is as sharp as the report of a 24-pdr. cannon, fired 40 yds. from the building, accompanied by a shaking of the ground. The same noises are frequently reported from the Bay of Fundy.

Mr. Kain says that while these sounds have generally been attributed to some form of earth disturbance, and are thus termed seismic noises, it is by no means certain that they may not often have an entirely different origin. The salt water drum-fish (Pogonias Chromis) is common on the Atlantic coast, and a large drum-fish will give out a sound that may be heard a long distance. As the sound is refracted into a nearly horizontal direction on its emergence from a level water surface, it may seem to come from a great distance, when it is really near at hand or under the vessel. There may be other fish of great size that can give forth louder sounds, and this may account for their variety. On the other hand, Mr. Kain believes that some of these oceanic noises defy all attempts at rational explanation.

Prof. Alexander Agassiz says that the large drum-fish atttains a length of more than 4 ft., but he cannot satisfactorily explain how the "drumming" is produced. Cuvier observes that it may depend on the air-bladder, though this has no direct communication with the open air; De Kay supposes it "to be occasioned by strong compression of the expanded phraryngeal teeth upon each other." Prof. Agassiz, from frequent examinations of the structure of the fish, is fairly satisfied that it is made in the air-bladder itself; that the vibrations are produced by the air being forced by strong muscular contractions through a narrow opening, from one large cavity—the air-bladder—to another cavity, that of the lateral horn. The sound itself, says Dr. Mitchell, most resembles the tap of a drum, and it is so loud that when many of the fish are gathered together it can be heard "several hundred yards from the water."

Prof. Wm. F. Ganong, of Northampton, Mass., writes to Mr. Kain and says that he cannot accept the drum-fish theory. He has heard the sounds from hills one-quarter mile from the sea, and they were too great in volume to be made by any number of fish. Mr. Kain is inclined to conclude that these sounds originate from different sources; some undoubtedly come from drum-fish; others are due to the heavy thud of breakers on cliffs; others to the cracking of rocks in ledges, such as light-houses frequently stand upon, and others still are occasionally due to genuine earthquakes occurring at the bottom of near oceans. In the latter connection it is well to remember that there are eight or ten well-defined regions on the North American continent within each of which there is a so-called center of seismic disturbance. There is no reason why similar centers should not exist under the ocean; and the great solitary waves occasionally reported by vessels sailing between Newfoundland and New York may sometimes be due to earthquake shock, as similar waves in the Pacific are known to have been caused by earth disturbance.

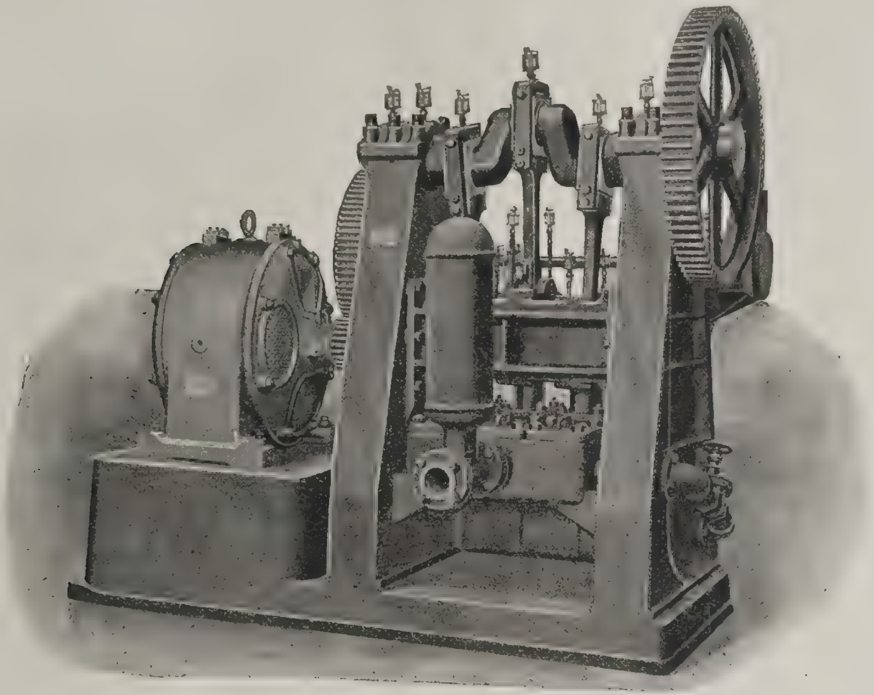

FIG. 1.—A WESTINGHOUSE THREE-PHASE MOTOR GEARED TO A GOULDS TRIPLEX PUMP.

AN ELECTRIC MOTOR FOR NARROW GAGE RAILWAYS.

We illustrate in the accompanying cut a new type of electric motor designed for narrow gage railway service with a minimum gage of one metre (39¼ ins.). In outward appearance this new motor resembles the motors for standard gage. It is built by the General Electric Co., of Schenectady, N. Y., for comparatively heavy service, such as is encountered in city and suburban traffic where the load carried at times is considerable and the speed moderate. The motor is designed for 500 volts and other regular electric railway conditions, and is rated at 37 HP. on a basis of a maximum temperature rise not exceeding 75° C. in the winding of field or armature after a full load run of one hour, provided the temperature of the surrounding air does not exceed 25° C. It weighs alone 1,865 lbs., and together with gear and gear case 2,150 lbs.

The magnet frame is cast in two parts, each containing two pole pieces bolted on from the outside. The upper half also has heavy lugs which are fitted with bearings for the car axle, upon which the motor rests, and other small lugs to which is bolted the suspension bar. The armature bearings are also bolted to this part of the frame. The bottom half can be lowered and the armature, commutator and bearing exposed for examination or repair.

The armature bearings are lined with 3-16-in. Babbitt metal swaged and bored to size. On the commutator end the bearing is 2⅝ × 6 5-16-ins., and the pinion end 3 × 7⅞-ins. All bearings are amply lubricated, are easily accessible and are designed to keep oil and grease away from armature and fields. The four wire-wound field coils surrounding the pole pieces are insulated with asbestos, are carefully wrapped with tape and cloth for insulation and protection, and are tested when in place with 5,000 volts alternating current between coil and field frame. The armature core is 14½ ins. in diameter and 6½ ins. in breadth, with 33 slots. The winding is "barrel-type," there being 3 coils in each slot. These are insulated and taped to form one coil for convenience in repairs. The coils are held in place in the slots by tinned steel wire wound around and soldered so as to form bands. The coil terminals are brought down and soldered directly to commutator segments. The commutator is 10 ins. in diameter and has 99 hard-drawn copper segments 4⅜ ins. long with a wearing depth of 1 in. The best grades of mica is used in its construction, and when completed it is tested with 5,000 volts between segments and shell and 500 volts between segments.

The brush-holders are mounted upon a block of treated wood attached to the upper part of the field frame, and are readily accessible by removing the hand-hole plate seen in the upper right-hand portion of Fig. 1.

AN ELECTRICAL PUMPING EQUIPMENT.

The illustration given herewith represents a combination electric pumping outfit, consisting of a type "C" three-phase induction motor built by the Westinghouse Electric & Mfg. Co., Pittsburg, Pa., and a vertical "Triplex" mining pump constructed by the Goulds Manufacturing Co., 16 Murray St., New York city. Such equipments are intended for use where the source of power is somewhat remote from the pump, and the pump here illustrated is designed for high pressures and has a capacity of from 60 to 150 gallons per minute to an elevation as high as 1,400 ft.

The motor is of the well-known "Tesla" type, and is built for circuits using 7,200, 3,600 or 3,000 alternations per second. It consists of a stationary part, known as the primary, permanently connected to the transmission circuits, which may be of any length, and a rotating secondary which is entirely disconnected from the primary, and consists of a series of thin steel disks, or laminae, mounted upon a suitable cast-iron spider. The disks have all around their outside square slots, and into these are slipped insulated copper bars which are connected at their ends to heavy copper rings. The revolving part is as solid and as free from liability to accident as an ordinary pulley wheel. This type of motor is especially remarkable in its simplicity. It possesses no commutator brushes, or collector rings and, consequently, requires very little attention. In addition it has a high commercial efficiency, a high power factor, and close speed regulation.

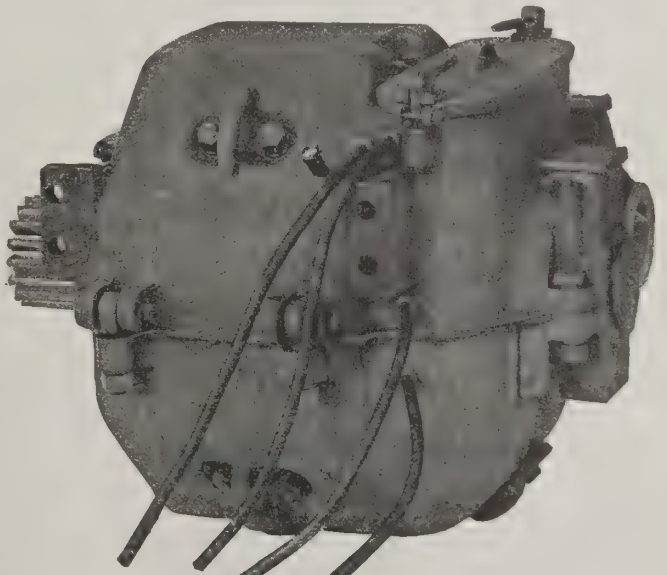
Starting up is accomplished by means of a double throw switch mounted upon a cast-iron case containing two auto-converters. These converters are connected across the circuit and are constructed to deliver a low electro-motive force to the motor. After starting the switch is thrown over and the motor is thus put directly on the main circuit. The starter may be some distance from the motor, for instance in mine pumping, it may be placed in the engine-room and the pump anywhere in the mine.

STATISTICS OF COMMERCE ON THE GREAT LAKES.

The Bureau of Statistics, of the U. S. Treasury Department, has issued an exceedingly interesting report upon the growth of traffic on the Great Lakes. It is practically the first comprehensive investigation of this subject since 1889, and the figures here gathered by Mr. George G. Tunell, of Chicago, are correspondingly valuable. For most useful purposes the report itself must be studied in all its detail, but some general figures are here given to illustrate this phenomenal growth in traffic, and to explain some of the reasons for it.

The astonishing development of the iron mines of the Lake Superior region, during the last 15 years, is very largely responsible for the enormous growth of traffic through the St. Mary's Falls Canal, and, in fact, throughout the Lake system. This development practically commenced in 1880, with but 677,073 tons of ore moved out of Lake Superior in the season; in 1895 the shipment of ore amounted to over 8,000,000 tons, or about one-half of the total of 16,806,781 tons passing the canal in that season. In 1897 the movement of ore exceeded all previous records and amounted to 10,633,715 net tons, with lumber, grain, flour and coal forming the other main items in an aggregate trade of 17,619,933 net tons.

These traffic statistics bring out a number of facts concerning the character of lake transportation. In the first place, this trade is exceedingly simple, consisting of but few commodities, and these are mainly crude products; at the time of the last census, iron ore, coal and lumber made up 75.73% of the tonnage of the lakes, and grain and mill products contributed 16.15% of the remaining 24.27%. The other elements of growth are the excessively rapid handling of freight, due to its simple character, the constantly increasing size of vessels, improved methods of supplying fuel to vessels, etc. Local traffic on the lakes is comparatively insignificant, nearly the whole commerce moving from one end of the system to the other; and a conspicuous feature is great preponderance of east-bound over west-bound freight. In 1890 the total east-bound commerce through the Detroit River in American vessels



A 37-HP. ELECTRIC MOTOR FOR NARROW GAGE RAILWAYS.

was 15,670,156 net tons, as compared with a westbound trade of 6,080,757 net tons; and this difference is more apparent still in the St. Mary's Canal.

The average registered tonnage of vessels has been constantly increasing; in 1870 the average tonnage of vessels passing the St. Mary's Canal was about 375 tons; in 1880 it was about 495 tons; in 1890, 800 tons, and in 1896 it was 926 tons. This statement, however, does not give a fair idea of the actual growth in the tonnage of vessels, as that of sailing vessels is about the same, and the tonnage of steamers shows no remarkable change until 1887. In 1886, the average gross tonnage of steamers was 269 tons; in 1891 it was 759 tons, and in 1897 it was 1,437 tons; or an increase of 534% in average tonnage in 12 years. The latest steamer building, for the Bessemer Steamship Co., is 475 ft. long over all, 50 ft. beam, and 29 ft. deep, and she will carry 6,500 to 6,750 gross tons on a mean draft of 17 ft. Mr. Tunell compares these dimensions with the two largest ocean steamers afloat, as follows:

	Bessemer steamer, ft.	"Kaiser Wilhelm der Grosse," ft.	"Oceanic," ft.
Length over all	475	648	704
Length on keel	455	...	685
Beam	50	66	68
Depth	29	43	46

In the matter of depth of hull, the shallowness of the lakes is responsible for the above disparity.

Steam is very rapidly supplanting sails on the Great Lakes; in 1864 there were 624 steamers, aggregating 144,117 gross tons, and 1,855 sailing vessels, of 293,978 gross tons. In 1897 the sailing vessels aggregated 334,104 gross tons; while there were 1,775 steamers aggregating 977,235 tons, and 101 barges of a total of 60,783 tons. In other words, while the number of vessels has changed but little since 1864—2,543 against 2,869—their total tonnage has increased from 438,095 to 1,372,122 gross tons.

In regard to freight rates, the tendency has been steadily downward. This is shown in a general summary of results, from 1887 to 1896, inclusive, which is condensed as follows:

General Summary of Freight Business from 1887 to 1896, Inclusive.

Season.	Total, ton-mile.	Total cost, transportation.	Cost per ton-mile, mills.	Average distance carried, miles.	Value of craft— American.	Value of craft— Canadian.	Carried by Canadian vessels, %.
1887............	4,458,544,804	$10,075,153	2.3	811.4	$17,684,550	$2,089,400	7.0
1890............	7,207,299,415	9,472,215	1.3	797.2	27,857,700	1,777,800	3.5
1895............	12,502,548,892	14,238,758	1.14	830.0	40,858,800	2,037,000	3.75
1896............	13,582,641,886	13,511,615	.99	836.4	43,006,200	2,135,300	4.0

The total estimated value of freight passing through the St. Mary's Canal alone has increased from $79,031,757 in 1887, to $195,146,842 in 1896. In this time the bulk of freight passing the same waterway rose from 5,494,649 net tons to 16,239,061 in 1896, and to 18,982,755 net tons in 1897.

The report enters largely into the flour and grain traffic; but while this is very important, the iron ore industry, as affecting lake transportation, is more generally interesting. The enormous amount of ore annually transported first arrests attention. In the navigation season of 1897, 10,633,715 net tons, out of a total of 18,982,755 tons passing through the St. Mary's Canal, were iron ore; and for the same year the total shipments of iron ore by lake from all the lake ports aggregated 13,681,522 tons. This means that approximately two-thirds of all the iron ore consumed by the blast furnaces of the country passes over the waters of the lakes in its way from the mines to the furnaces. The excellent quality of the Lake Superior ore and the cheapness of its extraction has made this change in the sources of iron ore supply in 15 years. In mining, the steam shovel is largely used to dig it and load it onto cars. During one day, in 1896, three steam shovels, working 14 hours each, dug and raised 10,700 gross tons, or 428 car loads of ore, from the Oliver mine, of the Mesabi range. Cars holding 25 tons each are being continually loaded from the ore-bed at the rate of 2½ minutes per car; and the largest shovel has loaded as much as 5,825 tons, or 233 cars, in 10 hours. This shovel weighs 90 tons, has a hoisting capacity of 200 HP., and is equipped with a 2½-cu. yd dipper and loads 5 to 6 tons at each swing. The estimated average cost of loading ore into the cars from the bed of the mine is considerably less than 5 cts. per ton. The cost of stripping the mine averages about the same; so that the aggregate cost of mining may be placed at less than 10 cts. per gross ton.

The cars used are especially designed for this ore traffic, and the expensive terminals are solely planned with a view to cheap handling of the ore. At some of these shipping ports the docks are built as high as 57.6 ft. above the water; and the ore-trains run upon them, dump the ore into pockets holding from 65 to 186 tons each, and from these pockets iron chutes lead directly to the holds of the vessels brought alongside the dock. Very little manual labor is required in this loading; though the ore has to be trimmed in the hold of the vessel at a cost of 2½ cts. per ton. The ore-receiving docks are similarly equipped with labor-saving devices. The chief item is the cost of shoveling the ore in the holds of vessels into the buckets; this charge amounts to 9 cts. per ton, and to this is added a dock charge of 5 cts., making 14 cts. per gross ton for the total expense of discharging iron ore. This ore, once in the buckets, is raised from the hold, carried back 350 ft. on the dock, and dumped, at a total cost of from 1 to 1½ cts. per ton, including labor, depreciation of plant, interest and fuel. Most of the ore is now loaded directly into cars and carried to furnaces located from 60 to 475 miles from the Lake Erie ports.

These improved loading and receiving docks are also partially responsible for the low transportation rates on the lakes; for instead of a vessel losing days in taking on and discharging cargo, this work is now done in a few hours. With the finely comminuted ores of the Mesabi ranges, which do not run so rapidly down the chutes as the hard and lumpy ores, 2,500 tons of ore can be put aboard a vessel in 70 minutes. At Two Harbors, 3,028 tons of hard ore were loaded in 70 minutes; and vessels frequently load and depart with a cargo of 3,500 to 4,000 tons within two hours of the time they reach port. With the appliances now in use for unloading, at the best docks, the largest vessels are unloaded in from 12 to 14 hours. At the new dock at Conneaut, O., to be operated in connection with the Bessemer Steamship Co. and the Pittsburg, Bessemer & Lake Erie Ry., it is expected that the largest vessels will be regularly unloaded in 10 hours; and it is hoped that in all but special cases this time will be reduced to 7 hours. The new plant is equipped with 12 "legs," one over each hatch in the vessel; and with all legs at work the capacity of the plant will be 900 to 1,000 tons per hour; or 7 hours for unloading a 6,000-ton ship. Owing to this perfection of transportation facilities, during the navigation season of 1896, large quantities of ore were carried from the head of Lake Superior to the lower lake ports, a distance of 889 miles, for 60 cts. per gross ton, or the equivalent of a ton-mile charge of only 0.67 mill. This low rate was even reduced to 50 cts. per ton, for some weeks in 1897, or a ton-mile rate of 0.56 mill. During the early spring of 1895, red hematite ore of Bessemer quality was delivered at Cleveland for $2.80 per ton; in the summer and autumn of 1896, the price of this ore varied from $4.00 to $4.25, and in 1897 it was as low as $2.00 to $2.50. The influence of low rates is shown by the fact that if the lake rate per ton-mile were 3 mills, which may be taken as the lowest rate that a railway could afford, the transportation charge from Duluth to Cleveland would be $2.54 per ton, or more than the traffic could bear. A table of the ore-shipping docks on the Great Lakes shows that the length of dock, in one case, is as much as 2,304 ft., with a width of 52 ft.; this dock, that of the Duluth, Missabi & Northern Railway, at Duluth, is 53 ft. 8½ ins. above the water, has 384 pockets, and an ore capacity of 57,600 tons. There are 21 of these docks on Lakes Superior and Michigan.

The coal traffic on the Lakes is important as furnishing the great bulk of the west-bound traffic; about 9,000,000 tons being shipped from the ports of Lakes Erie and Ontario in 1896. This trade from Buffalo, in 1873, amounted to only 570,443 tons, while that port shipped 2,400,068 tons of anthracite coal in 1896. The bituminous coal comes mainly from Cleveland, nearly 2,000,000 tons being shipped from that port in 1896. The chief western distributing points are Chicago, Milwaukee, Duluth and Superior, in the order named, but with Chicago handling two-thirds of the total. As with iron-ore, the handling of coal made necessary the development of facilities. The anthracite coal is usually loaded from pockets, and 5,127 net tons of this coal were lately put aboard the "Zenith City," at Buffalo, in 4 hours. In the loading of soft coal, however, very great innovations have been made. Until recently soft coal was shoveled, at a great cost, from cars to buckets, and then swung onto the ships by derricks; the loading is now done at the best docks by car-dumping machines, one of which, at Cleveland, loaded into a ship 5,176 tons of coal in 10 h. 30 m., at a total cost of $13, or ¼ ct. per ton. Coal is now generally unloaded by the self-filling clam-shell, or grab-bucket. In the best type a speed of three trips per minute is guaranteed, with an average load of one gross ton; it is also guaranteed that the total cost of removing cargo and delivering it in the yard shall not exceed 5 cts. per ton for the entire cargo. At one of the Milwaukee yards, two vessels, whose cargoes aggregated 7,776 tons, commenced discharging at 8 a. m. and were ready to leave at 8 p. m. For handling soft coal, a special form of "grate" has been devised. Coal rates are exceedingly low, owing to the scarcity of west-bound freight. The average of daily rates for 1896 was 24 cts. per net ton, from Buffalo to Duluth, or about ¼ mill per ton-mile.

Owing to the enormous drafts made during half a century upon the forests of Michigan, Wisconsin and Minnesota, the once seemingly inexhaustible timber supply of these regions is failing, and the lumber business on the lakes is waning. The lake shipment of lumber, from Saginaw River points alone, has steadily fallen from nearly 660 million feet, in 1885, to less than 90 million feet in 1897.

ANNUAL CONVENTION OF THE LEAGUE OF AMERICAN MUNICIPALITIES.

The second annual meeting of this association was held at Detroit, Mich., Aug. 1 to 4, and there was a very large attendance. The association is composed of cities, as corporations, which send numerous delegates and representatives. The attendance, therefore, included mayors, aldermen, public officers and a certain proportion of "politicians." In all, about 1,500 delegates were present, and the meetings were well attended. Owing to some hitch in the arrangements and the fact that the printed programs omitted to say where the meetings were to be held, the morning session of Aug. 1 was practically omitted, and the first regular session was called to order about 2.30 p. m. by the President, Mr. John MacVicar, Mayor of Des Moines, Ia.

Rev. C. L. Arnold opened the proceedings with prayer, after which the report of the Secretary was presented. In this it was stated that most of the work of the year had been in the direction of increasing the membership, and that in spite of certain interested antagonism, 72 cities are now members of the league. One of the most important departments is the bureau of information, which has issued three bulletins and answered 300 special enquiries, while a library of several hundred volumes has been collected. The report stated that, contrary to the requirements of the constitution, the Secretary had expended a large proportion of the receipts, without formal sanction, but that this had been necessary under the conditions. The receipts were $2,280, of which $590 was turned over to the Treasurer. The report of the Treasurer was then presented, and showed receipts of $590 and expenditures of $586.

Hon. H. S. Pingree, Governor of the State of Michigan, then delivered a short address of welcome, in which he pointed out that one of the most difficult and most important problems in municipal government is that of inducing the so-called "best citizens" to be something more than fault finders. He also favored trips by city officials to inspect the work and methods of other cities, and in this he is no doubt right, provided that these trips are not the mere junketing outings of aldermanic bodies and others which are somewhat too common, and are simply a means of wasting city funds.

The subject of "Garbage Disposal" was then opened by Mr. F. A. Walker, President of the Council of Trenton,

N. J., who prefaced his paper by the remark that it had purposely been made short, as he thought the best results of the convention would be obtained by an extensive discussion rather than by the presentation of the experience or opinions of one individual. He referred to the two systems of disposal by incineration and reduction, his own experience having been with the former, for the benefit of public health. At Trenton, a contractor is paid $6,000 per year for collecting and destroying the garbage (exclusive of night soil), the material being taken to a Dixon crematory, which has been in use for 2⅓ years, and has only cost $50 for repairs. It costs 30 cts. per ton for cremation alone. Night soil is carried five or six miles out by small contractors, who deal directly with the householders, while another contractor takes dead animals to a soap factory. Whatever system is used, should, in his opinion, be owned and operated by the city, as it is a matter of public necessity, and the collection should also be done by the city and not by contractors.

Mr. C. A. Collier, Mayor of Atlanta, Ga., said that all garbage, night soil, decayed fruit and vegetables, dead animals, etc., etc., is destroyed in a Dixon crematory four miles from the city. While this is thorough in operation, it is an expensive system, but nevertheless the city is quite satisfied, feeling justified in spending the money on behalf of the public health. The population is about 100,000, and the sanitary department expends $140,000 per year, which is considered money well spent.

Mr. F. B. Farnsworth, Mayor of New Haven, Conn., said that his city had an old-fashioned system of disposal which is not uncommon in the smaller cities. It lets contracts for the collection of garbage to men who have tracts of land and raise hogs, and what is not eaten by the hogs serves to fertilize the ground. The garbage includes nothing but kitchen refuse. He thought this system to be "good enough." The great trouble is to get the collecting properly done, as good men will not stay at this sort of work. At Worcester, Mass., a similar system is in force, but is under the supervision of the Superintendent of the Poor Farm, all the wagons, horses, etc., being owned by the city. One man is hired for each team, and with him goes one of the inmates. The garbage is utilized on the farm, as manure and food for hogs.

Mr. L. P. Whelan, Chairman of Council of Richmond, Ind., said the system of collecting by contract was not satisfactory, and this work had, therefore, been put in charge of the Health Officer. Garbage, night soil and refuse of every kind is carted to an Engle crematory near the river bank, in the middle of the city, natural gas being used for fuel. He did not think it well to insist upon the use of metal cans, as in winter the stuff freezes in the cans, which are damaged by the men breaking it loose for dumping.

Mr. Smith, of Moline, Ill., stated that in that city the collection of garbage is done under the supervision of the City Marshal. Mr. Hart, of New Orleans, referred to the trouble over the garbage contracts in that city, which has been fully described in Engineering News.

Mr. W. C. Maybury, Mayor of Detroit, said that his city has made a three-year contract at $50,000 a year, for collecting the garbage and delivering it on cars, which carry it out 15 or 20 miles to a reduction plant. It has happened that the contractors have done their work faithfully and well, but in view of the probabilities of carelessness and the evil results to public health which might attend such carelessness, he thought the city ought to do the garbage collecting. He argued that this formed an important part of the city's work in performing its duty to the health of its citizens, and that the responsibility should not be shifted to a contractor.

The meeting then adjourned, and the members proceeded to view an exhibition of throwing fire streams from a water tower and from the fire-boat on the river.

In the evening Mr. James A. Lavery, of Poughkeepsie, President of the Labor Federation of the State of New York, delivered an address on "The Relation of Municipalities to Organized Labor."

On Tuesday morning, Aug. 2, there was a reception by the Board of Education at the new Central High School, after which the regular meeting was held, the first subject taken up being "Administration by Boards, Single-Headed Commissions or Council Committees." Mr. W. E. Young, Mayor of Akron, O., favored the second plan, with one man at the head of each department, for water supply, fire protection, charity, etc. Mr. F. V. Evans, Mayor of Birmingham, Ala., strongly approved of the third plan, taking the view that the people's representatives should themselves attend to the affairs of their municipal government, and not delegate their authority or responsibility to boards or commissions.

An address on "Municipal Liberty, or Local Self-Government," was then delivered by Prof. Frank Parsons, of the University of Kansas. He did not approve of municipal affairs being so much under the control of the state legislatures, but thought each city ought to be allowed to govern itself without such general regulation. The comprehensive scheme of government suggested by him included municipal ownership of municipal industries, the initiative and referendum, and woman suffrage.

The afternoon session was opened by a discussion on "The Regulation of Saloons," in which most of the speakers presented liberal ideas, and denounced many of the present systems of restrictive regulation. The subject of "Street Paving" was then taken up, and Mr. R. J. Saltsman, Mayor of Erie, Pa., stated that asphalt and brick are now mainly used, on a concrete foundation, which is found to be superior to rolled gravel. The cost of asphalt is now $1.83 per sq. yd., with a five years' guarantee. Tramps are put to work cleaning the streets. Prof. Bemis, of the Kansas Agricultural College, gave an address on municipal ownership for electric lighting plants, and presented arguments and figures in favor of this system.

In the evening there was an entertainment at Belle Isle Park.

At the morning meeting on Aug 3 there was a large attendance, and the first subject taken up was "The Remuneration to Cities for Franchise Rights In, Over and Under Public Streets and Alleys." There was but little discussion, however. One of the speakers spoke strongly in regard to the point that improvement in municipal affairs can be secured only by citizens taking an active part in such affairs and not leaving them to politicians, who are financially interested.

The subject of "Public Water Supplies" was then opened by an address by Mr. James K. McGuire, Mayor of Syracuse, N. Y. This address described the growth of the present water supply system of that city, which is taken from Lake Skaneateles and flows by gravity to the city. Under corporate ownership, the distribution system was extended only on those streets where a remunerative return was assured, but very much better results have been obtained during the eight years of municipal ownership. Credit was given to Mr. Wm. R. Hill, M. Am. Soc. C. E., Chief Engineer, for his work in connection with this system, and for the introduction of day labor and the eight-hour day, which systems have been in use since Jan. 1, 1896. Mr. George Hillyer, President of the Water Board of Atlanta, Ga., then described the water-works of that city, where the water is forced up 500 ft. from the Chattahoochee River to a reservoir holding 30 days' supply, or 185,000,000 gallons. He strongly advocated the use of reservoirs of 20 to 40 days' capacity, especially where the water has to be filtered, as it facilitates the work of filtration. The most important part of his address was that in relation to the use of meters, the adoption of this system having reduced the fuel consumption and the pumpage to an enormous extent, and the pressure is now sufficient for fire purposes. The city is paid for about 57% of the amount consumed, and the maximum water rate is 10 cts. per 1,000 gallons. The consumer pays for the meter, and the city puts it in and keeps it in order. He favored mechanical filtration, as used at Atlanta.

Mr. M. H. Levagood, Mayor of Elyria, O., then exhibited a sample of the water supply of Painesville, O. There is a sand beach on the lake, kept clean by the wash of the waves, and in this a trench 800 ft. long was dug and filed with clean, sharp sand. The water percolates into this trench and flows through it to a cistern or tank, from which is drawn the supply for 7,400 people. The system has been in use for some years, and has cost practically nothing for repairs.

After the roll-call by cities the meeting adjourned. In the afternoon there was a boat ride on the river.

The morning session of Aug. 4 was devoted to a consideration of "Municipal Ownership of Public Service Industries," all the speakers favoring such ownership. Mr. Samuel F. Jones, Mayor of Toledo, O., read an address in which he referred to the various enterprises conducted by the city of Glascow, and pointed out that while people at large are patriotic enough to sacrifice position, health and life in time of war, they are lacking in that peace patriotism which would lead them to some self-sacrifice in the interests of their cities and their fellow-citizens. Mr. F. G. Pierce, Mayor of Marshalltown, Ia., and Mr. J. A. Johnson, of Fargo, N. Dak., also delivered addresses, taking the same general view.

In the course of the lengthy and animated discussion, one member asked how cities could acquire enterprises for which franchises have already been granted, without enormous expenses, which must be met by special taxation, general taxation or bonds. In answer to this, a delegate from Elwood, Ind., said that as the water company in that city did not give good service and could not be induced to sell out, the city built its own plant, and with such successful results that it is now arranging to build an electric lighting plant, raising the money by a tax of 8 cts. per $100. Prof. Parsons, of Kansas, said that at Springfield, Ill., a local lighting company was found which charged $150 per arc lamp. Of this amount, $60 is for the cost of lighting, and the balance is for interest, etc., and a sinking fund, so that in a few years, when the original investment has been paid, the plant will revert to the city without any further change.

Mr. Greene, formerly Mayor of Binghamton, N. Y., said that it should be borne in mind that a water or lighting company is in a legitimate business, and should be dealt with fairly and on a business basis, not as a criminal. He thought that even municipal ownership would be a failure without the civil service system and the exclusion of party politics. He thought every municipality should report to the state legislature, and after some further discussion a resolution was adopted in favor of such a plan, with a uniform system of accounting, while the resolution also provided that corporations conducting municipal enterprises should be required to report in a similar way. Prof. Bemis thought that a state legislature ought to have power to authorize a municipality to exceed its limit of debt, provided that the issue of bonds is for an existing plant as an asset, but in such case the charges must be sufficient to pay the interest and also form a sinking fund. Such a system is already in force in Massachusetts.

The afternoon session differed materially from the previous part of the meeting, the "politician" element being more in evidence, and the character of the proceedings somewhat resembling those of a ward meeting. The first business was the presentation of a report by the auditing committee, censuring the Secretary somewhat sharply for unbusinesslike methods and for not complying with the requirements of the constitution in regard to the conduct of the financial affairs. After a long and hot discussion this report was adopted, as were certain amendments to the constitution, by which the powers of the secretary are materially curtailed.

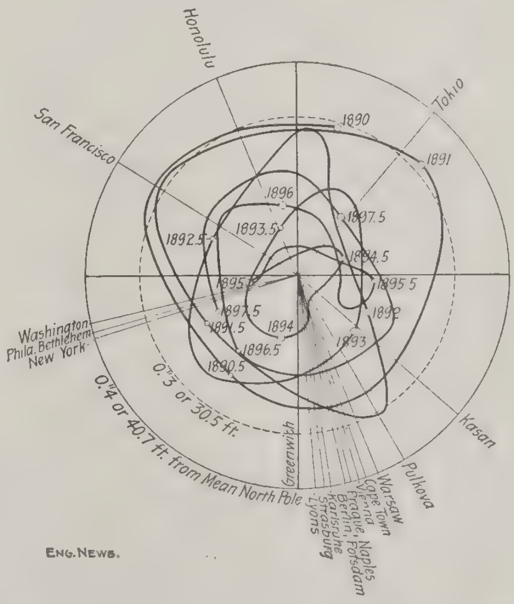
The election of officers resulted as follows: President, Samuel L. Black, Mayor of Columbus, O.; Vice-President, W. C. Maybury, Mayor of Detroit, Mich.; Treasurer, M. Taylor, Mayor of Bridgeport, Conn.; Secretary, B. F. Gilkison, New York city. It was also voted that the next meeting should be held at Syracuse, N. Y.

The exhibitors were few, and comprised the following firms: Dixon Garbage Crematory Co., Toledo, O.; Seagrave & Co., Columbus, O. (fire ladders and trucks); U. S. Voting Machine Co., Jamestown, N. Y.; International Street Sweeping Machine Co., Dayton, O.; Welsbach Light Co., New York, N. Y.; and the Atlas Cement Co., New York. The DeCarlie automatic compressed air catchbasin cleaner was also exhibited.

BOOK REVIEWS.

BERICHT UEBER DEN STAND DER ERFORSCHUNG DER BREITENVARIATION. (Report on the Status of the Investigations Concerning Variation of Latitude.)—By Th. Albrecht. Berlin: Georg Reimer. 1898. Quarto; pp. 36; 1 plate.

This report is one of the valuable publications of the International Geodetic Association, an association which has done much good work during the past twenty years in unifying the methods of geodesy and perfecting our knowledge regarding the shape and size of the earth. Dr. Albrecht here gives the results of the measurements on latitude variation made at twenty observatories in different parts of the world, determines their relative precision, and combines them so as to deduce a curve showing the motion of the north pole of the earth's axis from Jan. 1, 1890, to July 1, 1897. In the following figure this curve is shown, 90.0 being the point for Jan. 1, 1890, while 90.5 is the point for July 1, 1890, and so on. The center of the figure is the mean position of the north pole for the 7½ years under consideration. In 1890 the pole made about seven-eighths of a circuit around its mean position; in 1891, but little more than three-fourths of a circuit, while in 1892 nearly the entire revolution was effected. The two circles drawn at 0.3 and 0.4 seconds of latitude from the mean pole give the scale of the figure, the radii of these circles being 30.5 and 40.7 ft., respectively. It should be noted that the north pole, which may be defined as the north end of the earth's axis, does not really move, since the axis remains parallel to itself throughout the year, but it is the earth which moves with respect to the axis; it is more convenient, however, to speak of the pole as in motion and the figure shows its path relative to the earth surface.



Positions of the North Pole, Jan., 1890, to July, 1897.

The practical consequence of this strange phenomenon is to cause a continual variation in the observed latitudes of all points of the earth's surface, for latitude expresses the angular distance from a point to the equator, and of course the equator moves with the pole, the plane of the equator being always perpendicular to the axis. For example, suppose that a certain point in our office had the latitude 40° 42′ 58.93″ on Jan. 1, 1891; if observations had been taken throughout the year it would have been found that this slowly decreased until in August it became about 40° 42′ 58.41″, and that an increase then followed until at the beginning of 1892 the observed latitude became about 40° 42′ 58.67″. It is thus seen that decimals of a second in astronomical latitudes do not have the precision which was formerly attributed to them.

The lines radiating from the center of the figure show the directions to the cities whose observatories furnished the data for deriving the curve. Of course, all these directions are south. The large number of observatories taking part in the work indicates the importance of the subject to astronomers and geodesists. The observations at Honolulu were conducted simultaneously by the International Association and by the U. S. Coast and Geodetic Survey from June, 1891, to July, 1892; simultaneously others were made by the Naval Observatory at Washington and by the Coast Survey at Rockville, Md. Those at New York were made at the observatory of Columbia University in 1893 and 1894. The most extensive series made in the United States is that conducted by Prof. C. L. Doolittle at the observatory of Lehigh University, in Bethlehem, Pa., which covers nearly four years. All these observations of latitude are made by the zenith telescope method. The curve given in the figure is the most probable one, derived by Dr. Albrecht from a discussion of all the records, and its degree of precision may be inferred from his conclusion that the probable error of location of a point of the curve is about 0.03″ of arc, which corresponds closely to 3 ft. in distance.

Dr. Albrecht does not discuss the theory of the motion of the pole or give the equation of its path. We understand, however, that this has been done through the analysis of Prof. Chandler, of Harvard University. It is established that the pole makes a circuit around a certain center in 428 days, and that this center at the same time makes a circuit around the mean position in 365 days. The combined effect of these two motions is to cause the period of rotation to vary between 422 and 434 days and the distance of the actual from the mean pole to range from 16 to 36 ft. Whether this theory explains fully the curious path of the pole in 1895, when the motion appears to be reversed in direction, we are unable to state.

THEORY AND CALCULATION OF CANTILEVER BRIDGES.—By R. M. Wilcox, Ph. B., Instructor in Civil Engineering, Lehigh University. New York: D. Van Nostrand Co. Pasteboard; 3¾ × 9 ins.; pp. 108; illustrated; 50 cts.

This volume is published to replace the original No. 25, "Theory and Calculation of Continuous Bridges," by Prof. Mansfield Merriman, of "Van Nostrand's Science Series." The change of name and scope of the volume was considered advisable from the fact that the continuous girder has gone entirely out of use, except for swing bridges, and the cantilever bridge has taken its place. The book is divided into three chapters, the first of which is a brief history of cantilever bridge building, with short references to the larger structures of this type constructed in Europe and America. Chapter II. treats of the theory of the cantilever and the calculation of of strains under the conditions of loading common in highway structures, and Chapter III. is devoted to a similar consideration of railway cantilever bridges. The book is clearly written and provides a very handy little treatise on the subject which it covers.

HOW TO BUILD FIREPROOF AND SLOW-BURNING.—By Francis C. Moore, President of the Continental Fire Insurance Co. Author of "How to Build a House, etc." Continental Print, New York. Pamph.; 5¼ × 8¼ ins.; pp. 74, + 20. 10 cts.

Mr. Moore is the representative of the New York Board of Fire Underwriters, on the Board of Examiners of the Building Department of New York city. His pamphlet contains many interesting and valuable hints in regard to fireproof and slow-burning construction, together with a considerable number of statements which are based on insufficient information and are calculated to do harm rather than good. We commented editorially in our issue of June 30 on Mr. Moore's defence of cast-iron columns, and need only say here that he continues to advocate them in this book. He also betrays his well-known prejudices against concrete floor constructions, steel rivets, which he declares "are dangerous and should never be used, unless of a very superior quality," and curtain walls. He seems to think that the curtain wall as ordinarily used with steel skeleton construction is not thick enough to confine the heat in case fire occurs and prevent the ignition of adjacent buildings; but he gives no facts in support of this view, and we believe he would find it difficult to do so.

When Mr. Moore turns to matters more strictly in the field of fire protection, however, he lays down some sound principles, and his little book may be profitably studied by any engineer who will be careful to distinguish what is really sound and valuable from that which is based on prejudice and misinformation. Some of his suggestions, such as that of a glass floor for dynamo rooms, are novel and interesting.

WORKINGMEN'S INSURANCE.—By William Franklin Willoughby, United States Department of Labor. New York: Thomas Y. Crowell & Co. Cloth; 5½ × 8 ins.; pp. 386; tables; $1.75.

That this book might prove of great practical interest and value to some of our readers will be evident when it is stated that acording to its author workingmen's insurance abroad has developed very largely from the unsatisfactory working of laws relating to employers' liability. Such laws have proved inadequate for modern industrial conditions, both in the opinion of many employers of labor, of the laborers, and of legislators. Mr. Willoughby describes clearly and concisely what has been accomplished in the way of workingmen's insurance both in European countries and the United States. Both voluntary and compulsory insurance have been tried abroad, the former most notably in Germany. Some of the countries which neither make insurance compulsory nor provide it by governmental agencies have done much in the way of regulating private voluntary insurance. In the United States most of the attempts at workingmen's insurance described by the author are railway relief associations. Some space is also given to trade associations. The kinds of insurance described in this book are accident, sickness, old age and invalidity, and to a less extent life insurance proper. A few pages are devoted to insurance against lack of employment. One of the best chapters in the book is a critical discussion of the whole subject presented in the form of conclusions. Strange to say, the volume is without an index, a serious omission.

PROGRESS IN TIMBER PHYSICS.—Influence of Size on Test Results, and Distribution of Moisture. Circular No. 18, U. S. Department of Agriculture, Division of Forestry. B. E. Fernow, Chief of Division. Paper; 11½ × 9¼ ins.; pp. 20; diagrams.

This circular gives the detailed results of experiments conducted by Prof. J. B. Johnson, of Washington University, and Mr. S. T. Neely, C. E., under the heads indicated in the title. The most important conclusions may be stated briefly as follows:

1. A difference in strength values derived from a few specimens of the same kind of wood, up to 10% for coniferous wood and to 15% for hard woods, cannot be considered a difference of practical importance; such differences cannot be relied upon as furnishing a criterion of the quality of the material. 2. The size of the test piece does not in itself influence strength values (except in compression endwise when the size is less than a cube). 3. Small test pieces judiciously selected furnish a better statement of average values of a species than tests on large beams and columns in small numbers. 4. A large series of tests on small pieces will give practically the same result as such a series on large beams and columns, hence there is no need of finding a coefficient with which to relate the results of the former to construction members. 5. The influence of moisture on strength appears even greater than the former tests and statements from this division have indicated. The most important discovery of all, worked out by Mr. S. T. Neely, may be stated as follows: The strength of beams at elastic limit is equal to the strength of the material in compression, and the strength of beams at rupture can, it appears, be directly calculated from the compression strength; the relation of compression strength to the breaking load of a beam is capable of mathematical expression.

PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.—Forty-sixth Meeting, held at Detroit, Mich., August, 1897. Published by the Permanent Secretary. Salem, Mass. 8vo.; paper; 80, 499.

This volume contains, in addition to a list of officers, members and fellows, the Constitution of the Association, very brief abstracts of some of the scientific papers read at the Detroit meeting, and titles of the others, the addresses of the several vice-presidents of the Association before their respective sections, and the address of the retiring president, Dr. Theodore Gill. The latter was a memorial address on the life and work of Edward Drinker Cope, the distinguished naturalist, who had been elected to preside at the Detroit meeting, but who died a few months before. The titles of the addresses of the vice-presidents before the several sections are as follows: Section A—Mathematics and Astronomy. W. W. Beaman: "A Chapter in the History of Mathematics." Section B—Physics. Carl Barus: "Long-Range Temperature and Pressure Variables in Physics." Section C—Chemistry. William P. Mason: "Expert Testimony." Section D—Mechanical Science and Engineering. John Galbraith: "The Groundwork of Dynamics." Section E—Geology and Geography. I. C. White: "The Pittsburg Coal Bed." Section F—Zoology. L. O. Howard: "The Spread of Land Species by the Agency of Man; with Especial Reference to Insects." Section G—Botany. George F. Atkinson: "Experimental Morphology." Section H—Authropology. W. J. McGee: "The Science of Humanity." Section I—Social and Economic Science. Richard T. Colburn: "Improvident Civilization."

It may be of interest to note the relative space given in this volume to the proceedings of the several sections, as follows: A—Mathematics and Astronomy, 62 pages. B—Physics, 30 pages. C—Chemistry, 27 pages. D—Mechanical Science and Engineering, 25 pages. E—Geology and Geography, 24 pages. F—Zoology, 38 pages. G—Botany, 44 pages. H—Authropology, 102 pages. I—Social and Economic Science, 68 pages. Some of the statistics of the Association are also instructive. Its jubilee of the 50th anniversary will be held in Boston this year. The membership in 1897 was 1,610, the lowest figure since 1880. In 1883 the membership was 2,033, and from that date until 1896 it fluctuated between 2,054 (in 1891) and 1,802 (in 1896). The attendance at the Detroit meeting was 283, the lowest figure since 1879, when it was 256. There is abundant evidence in these figures that the Association is not filling the place that it should. In fact, for many years it has shown symptoms of decay. One cause, no doubt, is the wretched system of publication of its proceedings, of which this volume is one of the worst examples. Few of the addresses, which occupy the greater bulk of the volume, are of any permanent importance, and the rest of the book is scarcely worth garret-room. The society is about entering on a new regime, however. It has organized a committee on "Policy of the Association," which is expected to devise ways and means not only of preventing the death of the Association, but of infusing into it new life and making it creditable to American science and scientific men.

THE MINERAL INDUSTRY.—Its Statistics, Technology and Trade in the United States and Other Countries to the End of 1897.—Edited by Richard P. Rothwell, Editor of the "Engineering and Mining Journal." Vol. VI., supplementing volumes I. to V. The Scientific Publishing Co., New York and London. 8vo.; cloth; pp. 903; $5.

The sixth annual volume of "Mineral Industry" is a worthy companion of its five predecessors. It resembles them in being a most extensive collection of the statistics of about 100 different mineral substances, with brief statements concerning the location of their principal sources of supply, the history, the business prospects and the mineral and metallurgical development of each branch of the industry. It contains also a great number of articles on special subjects related to the mining industry, written by specialists in these subjects. We give the titles and the names of the writers of some of the principal writers below:

"Calcium Carbide and Acetylene," by Alfred H. Cowles; "The Manufacture of Hydraulic Cement in the United States," by Frederick H. Lewis; "Progress in Electro-Chemistry in 1897," by H. Borns; "Clay Ballast—Its Methods of Manufacture and Cost," by H. Foster Bain; "The By-Product Coke Oven," by W. H. Blauvelt; "Cyaniding Telluride Ores," by Philip Argall; "Gold Mining in South Africa,' by E. D. Chester; "The Quicksilver Industry of Italy," by Vincente Spirek; "The Rare Elements," by L. M. Dennis; "Slate," by H. L. J. Warren; "Tunnel Rights Under the United States Mining Law," by R. W. Raymond; "Progress in Ore Dressing in 1897," by Robert H. Richards; "Fatal Accidents in Coal Mining in the United States and Canada," by Frederick L. Hoffman.

The volume contains a very complete index, containing, it is said, over 16,000 titles. We are informed that "Mineral Industry" was recently awarded a gold medal by the French De La Societe D'Encouragement Pour L'Industrie Nationale in testimony of the service which it is considered to have rendered in the promotion of industry in France.

DIRECTORY TO THE IRON AND STEEL WORKS OF THE UNITED STATES.—Embracing a Full List of all the Blast Furnaces, Rolling Mills, Steel Works, Rail Mills, Structural Mills, Plate and Sheet Mills, Tinplate Works, Steel-Casting Works, Wire-Rod and Wire Mills, Cut-Nail Works, Wire-Nail and Horse-Nail Works, Bolt, Nut and Rivet Works, Chain Works, Stamping Works, Bridgebuilding and Shipbuilding Works, Car-Axle, Car-Wheel and Carbuilding Works, Locomotive Works, Malleable Iron Works, Tube Works, Pipe Works, and Forges and Bloomaries. To which is added a complete list of the Iron and Steel Works of Canada and Mexico. 14th edition; corrected to April 1, 1898. The American Iron and Steel Association, 261 So. 4th St., Philadelphia. Cloth; 8vo.; pp. 380; $7.

The Directory of Iron and Steel Works is published every two years. The present edition is much larger and more complete than any of the earlier editions. The long sub-title above gives a general idea of its contents. The names and location of the works are given, arranged by geographical districts and alphabetically, followed usually by a description of their character, capacity and products, with the names of the principal officers. The iron and steel works of the country have a splendid organization for collecting statistical information, and the present directory is a credit both to Mr. Swank, the secretary and general manager of the Association, and to the whole American iron trade. We notice that two of the steel works, the Midvale and the Black Diamond, following their custom of previous years, have declined to furnish any information for the directory. Their action is odd, to say the least.

REGULARIZATION DU MOUVEMENT DANS LES MACHINES.—Par L. Lecornu. Ingenieur en Chef des Mines. (Encyclopedie Scientifique des Aide Memoire.) Gauthier-Villars et Fils, Paris. Paper; 4½ × 7½ ins.; pp. 217; 3 francs.

The theory of regulators of movement in machines, or governors, as they are usually called in English, is one of unusual difficulty to students. The present work may clear up some of the difficulties for those who can read French and who enjoy wrestling with equations in calculus. It is divided into two parts. The first treats of the theory of governors with indirect action, and is borrowed from the work of M. Leaute and put in accessible form. The second, or governors with direct action, is drawn from a memoir of M. Lecornu, for which he received the Fourveyron prize of the Academie of Sciences in 1895. The theory of governors, interesting in itself, leads to conclusions of practical value, for from it are formulated rules which should be followed by builders of machines in order to insure them a regular speed.

ENGINEERING NEWS
AND
AMERICAN RAILWAY JOURNAL.

VOL. XL. No. 7.

TABLE OF CONTENTS.

ENGINEERING NEWS OF THE WEEK............ 97
Ornamental Bridges for Lake Park, Milwaukee, Wis. (illustrated) 98
The West Superior Coal Storage Plant of the Lehigh Valley Coal Co. (with double-page plate and other illustrations) 99
The Shearing Strength of Rivet Steel (illustrated).. 100
The Cowles System of Water-Tight Bulkhead Doors for the U. S. Cruiser "Chicago" (illustrated)...... 101
Notes at Detroit 102
A German Clamp Connection for Staging Construction (illustrated) 103
Water Supply from the Sand Dunes of the Netherlands 103
Bushed Pin Connections for the Surprise Creek Arch; Canadian Pacific Ry. (illustrated) 103
The New Settling and Aerating Basins, Ft. Smith, Ark. (illustrated) 107
Gun-Fire Analysis of the Santiago Sea-Fight........ 107
A Higher Industrial and Commercial Education.... 108
An Electric Coal Mining Plant in Pennsylvania (illustrated) 109
Track Elevation of the Erie R. R. Through Jersey City, N. J. (illustrated) 111
Book Reviews 111
Weather Table for July 112
EDITORIAL NOTES 104
Promotion of Engineer Officers for Services in the Santiago Naval Battle—Services of the Engineer Officers in the 15,000-mile Run of the "Oregon"—Water Purification for Army Camps—The Danger of Overcrowding the Surface Car Traffic on the Brooklyn Bridge—The Duty of the Good Citizen in Securing Efficient Administration of Municipal Works.

EDITORIAL:

The Value of Extreme Fineness of Grinding for Hydraulic Cement 105

LETTERS TO THE EDITOR:

Report on the Condition of the Paints on the 155th St. Viaduct, New York City—The "Arithmetic of the Steam Engine" Again....................... 106

THE TRIP OF THE BATTLESHIP "OREGON," from Puget Sound to Key West, is described from a steam engineer's point of view in a letter written by First Assistant Engineer C. N. Offley, U. S. N., in charge of the starboard engine-room of the "Oregon." From this interesting letter, as published in the New York "Sun," we learn of the extreme watchfulness with which all the machinery of this ship was overhauled and cared for on the memorable trip. He gives a summary of the runs and coal consumption, which supplements a table already published by the Navy Department. In the following record the time while entering and leaving port is eliminated, the run commencing when the ship was fairly under way; the coal record does not include that used while in port, but does include coal consumed for all purposes while at sea:

From	To	Distance, knots.	Time, hrs.	Speed, knts pr hr.	Coal, tons.	Knots per ton coal.
Bremerton	San Francisco.	827.7	72	11.49	221.0	3.74
San Francisco	Callao	4,076.5	371	10.99	962.0	4.24
Callao	Port Tamar	2,529.9	212	11.93	785.0	3.22
Port Tamar	Sandy Point	132.0	9	14.55	66.0	2.00
Sandy Point	Rio de Janeiro.	2,247.7	223	10.08	657.0	3.42
Rio de Janeiro	Bahia	700.0	*	*	288.0	....
Bahia	Barbadoes	2,229.0	193	11.55	620.0	3.59
Barbadoes	Jupiter	1,683.9	142	11.86	478.5	3.3
Jupiter	Key West	280.0	27	10.37	77.9	3.6
Total		14,706.7			4,155.4

THE TEMPERATURE OF WARSHIPS, at least in the fireroom, is usually something abnormal, and the "Cincinnati," an armored cruiser, has registered as high as 205°F. under forced draft. In both this ship and the "Raleigh," now with Admiral Dewey, this terrific fireroom heat is charged to reduced boiler space, under English rules, which crowded machinery of a high nominal power into a small space. When these ships were built the Engineering Department demanded room to install the boilers properly, but as 15 ft. would thus have been added to the 300 ft. fixed for the ship's length, the request was refused. It is pointed out that the specifications for the new battleships tempt builders to utilize the space provided by crowding into it high-power machinery, which will lead to like results. This is another incentive for reopening the whole question of design for these new ships; and late experience in tropical regions should in itself tend to a more decided regard for the health and comfort of the men in the fireroom. This part of the ship should be made at least endurable for the men whose services are too often overlooked in counting up our heroes.

◆

THE ABSENCE OF HEAVY GUNS on the "Christobal Colon" in the Santiago fight is explained as follows by "La Tribuna di Roma:" The Spanish authorities refused to accept the two 254 mm. (about 10-in.) guns built at the Armstrong works at Pozzuoli for this ship, alleging defects in the sighting appliances. These were to have been replaced by two 9.6-in. Hontoria guns, but for some reasons which the Spanish naval authorities can alone explain, the "Colon" was sent to Cuban waters with guns of only about 5-in. caliber.

◆

AN INCREASE IN THE CIVIL ENGINEER CORPS, U. S. N., is asked for by Commodore Endicott, Chief of the Bureau of Yards and Docks. At the present time this corps numbers 15 officers in all grades, and of this number, Mr. R. E. Peary is on leave in connection with his Arctic work. Messrs. A. G. Menocal and U. S. G. White are suspended from duty, and one or more others are on sick leave. This reduction in the active list especially embarrasses the service at this time, and the Chief of Bureau asks that the corps be permanently enlarged to 20 officers. As at present constituted, this corps includes one officer with relative rank of Captain, U. S. N.; two with the relative rank of Commander, one of whom, Mr. M. T. Endicott, is now Chief of Bureau, and ranks as a Commodore; three officers ranking as Lieut.-Commanders; four ranking with Lieutenants, and six ranking relatively with Lieutenants of the junior grade.

◆

THE PLANS FOR RAISING the "Christobal Colon" are progressing under Naval Constructor Hobson. He has lately been experimenting with large rubber bags, or collapseable caissons. It is proposed that each of these shall have a lifting capacity of ten tons, and that they shall be lashed in place and inflated when sunk. The experiments being made at New York are to determine the strength and power of the bags and the efficiency of the air-valves.

◆

HIGHER SPEEDS IN THE NEW BATTLESHIPS, "Maine," "Missouri" and "Ohio," are promised by at least five prospective bidders, in communications to Secretary of the Navy Long. These shipbuilders include the Cramps, of Philadelphia, the Newport News Co., the Union Iron Works, of San Francisco, John A. Dialogue & Co., of Camden, N. J., and the Harlan & Hollingsworth Co., of Wilmington, Del. These firms propose to submit their own designs for hull and machinery, subject to the approval of Chief Naval Constructor Hichborn and Engineer in Chief Mellville. They provide that should these plans be satisfactory and speed greater than 16 knots be assured, the contract will be made with the successful firm.

◆

A CLOUD-BURST occurred on Aug. 13 about 20 miles from Rogersville, Tenn., in which 17 persons were killed and several others injured.

◆

A RAILWAY ACCIDENT near Genoa, Italy, in which 9 persons were killed and 40 seriously injured, is reported to have occurred on Aug. 11. A heavy freight train drawn by three engines became stalled on a steep grade in the Glori Tunnel. The tunnel soon filled with gases from the engines, which asphyxiated the engine drivers and firemen, leaving the train to run backward and crash into a passenger train standing at the entrance of the tunnel.

◆

THE MOST SERIOUS RAILWAY ACCIDENT of the week occurred Aug. 10 near Pennington, Va., on the Louisville & Nashville R. R., as the result of a landslide. Three coaches rolled down a 60-ft. embankment, injuring about 20 persons, one or two quite seriously.

◆

CHINESE RAILWAY AFFAIRS appear to be making some progress. A line is now under construction from Peking to Pao-ting-fu, 90 miles, and we learn that a Belgian company has closed an agreement with Director-General Sheng for the construction of a line from Pao-ting-fu to Hankow, a distance of about 600 miles. The railway from Shanghai to Woosung, 9½ miles, is expected to be opened for traffic about the end of August.

◆

THE PARIS EXHIBITION OF 1900 will have a very large representation from the United States, and thus far the space allotted to the various departments is given as follows by Mr. Ferdinand W. Peck, Commissioner-General for the United States:

	sq. ft.
Agriculture and food products	20,000
Army and navy	3,300
Chemical industries	5,160
Education, instruments, practical sciences and arts	11,470
Fine arts	(not yet known)
Forestry, hunting and fisheries	3,300
Heating apparatus	4,500
Horticulture	(not yet known)
Machinery and electricity	50,000
Manufactures	25,000
Mines and mining	7,700
Textiles	13,000
Transportation and civil engineering	20,000
Total	163,430

◆

THE FIRST AMERICAN LOCOMOTIVE for England has just been finished by the Baldwin Locomotive Works. It is a double-ender, intended to run between Barnstaple and Lynton, the latter place being a sea resort about 15 miles from Barnstaple.

◆

THE LARGEST FREIGHT TRAIN EVER HAULED left Altoona, Pa., on the Pennsylvania R. R., bound for Columbia, Pa., on Aug. 9. The train was made up of 130 coal cars and was 3,877 ft., or only a little less than ¾ of a mile long, and weighed, exclusive of engine and tender, 5,212 tons, of which 3,693 tons was coal. Engine No. 872, belonging to Giant 45 class, which weighs 118 tons, and is considered to be the largest in the world, hauled the train. The 132 miles from Altoona to Harrisburgh were covered in 12 hours; in other words, the train made an average speed of 11 miles per hour.

◆

TRACK ELEVATION IN CHICAGO has been carried on vigorously during the past two or three years, but at the end of 1897 less than half the work called for by existing ordinances had been completed. The following is an extract from the annual report of Mr. John O'Neill, Superintendent of Track Elevation:

Total track elevation provided for by ordinances	45.7 miles.
Total track elevation completed Dec. 31, 1897	19.0 miles.
Total track elevation to be effected	26.7 miles.
Total grade crossings abolished by ordinances	243
Total grade crossings eliminated Dec. 31, 1897	86
Total grade crossings to be eliminated	157
Cost of work provided for by ordinances	$16,130,000
Cost of work executed, Dec. 31, 1897	$6,050,000
Cost of work yet to be done	$10,080,000

During the present year considerable work has been done by the Chicago, Milwaukee & St. Paul Ry., the Pennsylvania Lines, and by the Atchison, Topeka & Santa Fe Ry. at the complicated 16th St. crossing (Eng. News, July 14, 1898). The following is a list of the track elevation ordinances passed up to the end of 1897:

May 3, 1892—Illinois Central R. R., 47th St. to 71st St.; 3 miles; 13 crossings; $2,000,000. Completed.

July 9, 1894—Chicago, Rock Island & Pacific Ry. and Lake Shore & Michigan Southern Ry., from 16th St. to 69th St. and 67th St. respectively; 8½ miles; 41 crossings; $3,000,000. Nearly completed.

Feb. 18, 1895—Chicago & Northwestern Ry. (Galena Division); Sacramento Ave. to 46th St.; 2½ miles; 6 crossings; $400,000. Completed.

March 30, 1896—Chicago & Northwestern Ry. (Milwaukee Division); Wrightwood Ave. to Rosehill cemetery; 4½ miles; 20 crossings; $900,000. Completed. (Wisconsin Division); Armitage Ave. to N. 44th Ave.; 4½ miles; 48 crossings; $1,000,000. Work done in 1898.

July 27, 1896—Pittsburg, Fort Wayne & Chicago Ry.; 55th St. to 67th St.; 2 miles; 13 crossings; $750,000. Work partly done.

Jan. 18, 1897—Pittsburg, Fort Wayne & Chicago Ry.; State St. to Laurence Ave.; 1 mile; 2 crossings; $150,000.—Lake Shore & Michigan Southern Ry.; 61st St. to Laurence Ave.; 2 miles; 2 crossings; $1,000,000. Work partly done.—Chicago & Northwestren Ry.; Rockwell St., from Kinzie St. to Ogden Ave.; 2 miles; 19 crossings; $1,000,000. Completed.

May 17, 1897—St. Charles Air Line at 16th St.; 3 miles; 8 crossings; $2,000,000. Work in progress.

Dec. 2, 1897—Chicago & Northwestern Ry. (Milwaukee Division); Chicago Ave. to Diversey Ave. and Wood St.; 3 miles; 27 crossings; $1,200,000.—Chicago, Milwaukee & St. Paul Ry. (over the C. & N. W. Ry.); Chicago River bridge to Paulina St.; 0.5 mile; 3 crossings; $100,000.—C. M. & St. P. Ry.; Irving Park Boulevard; 6 miles.—C., M. & St. P. Ry. (Pacific Junction Branch); 0.6 mile.

◆

A NEW WIRE ROD MILL of the most modern type is about to be built by Mr. William Garrett for King, Gilbert & Warner, at Columbus, O. The mill will use a 5-in. square billet, which is taken from the billet mill, after being sheared into lengths, to a heating furnace, where it is given a light wash heat, and then is delivered direct into the rod train. A letter from Mr. Garrett to the "Iron Trade Review" gives the reasons for locating the mill in Columbus, which is interesting in showing how the minor economies are being considered in modern steel works. We quote from it as follows:

> In the past, Messrs. King. Gilbert & Warner have shipped the major part of their production to wire rod mills in Cleveland, in the shape of 4-in. billets, which, after being rolled into rods, have been reshipped through Columbus, to a large wire mill in Cincinnati. Owing to the keen competition in 4-in. billets, this see-sawing in the transfer of freight could not be tolerated. The freight on the billets from Columbus to Cleveland is 65 cts. per ton, and the freight on rods from Cleveland to Cincinnati is $1.20 a ton, making $1.85 per ton. Had the wire rods been manufactured at Columbus, the freight from Columbus to Cincinnati, 55 cts. per ton, would be the only expenditure for transportation, showing a clear saving of $1.30 per ton in freight. There is a further saving of about 50 cts. per ton in the manufacture of wire rods, when taking the hot billet, which is rolled from the initial heat of the ingot, and rolling this billet before it is cold into wire rods, making a saving of $1.80 per ton in favor of making wire rods in Columbus.
>
> It may be said there are already too many wire rod mills in this country, which can now produce far more than we can at present consume. True; but are they correctly located to avoid this duplication of freight charges, and in such position relative to the steel mills as to take advantage of the initial heat of the ingot?
>
> The day is not far distant when no firm that makes pig iron can afford to let it leave the works until it has taken advantage of the initial heat of the metal in every stage of manufacture, to put it into a marketable shape, which is entirely feasible in the case of merchant steel and wire rods.

◆

THE POWER PLANT of the Hudson River Power Transmission Co. was started up on Aug. 9. This plant, it will be remembered, is situated about 18 miles from Schenectady, N. Y., and includes a concrete dam 2,000 ft. long and 18 ft. high, and a power-house which will eventually contain 28 250-HP. turbines driving 7 750-K-W. three-phase General Electric generators. At present only 5 generators are in place, and the current from these is transmitted to Schenectady, where it is used to operate a portion of the machinery of the General Electric Works.

ORNAMENTAL BRIDGES FOR LAKE PARK, MILWAUKEE, WIS.

We illustrate herewith a number of park bridges designed by Mr. Oscar Sanne, as Consulting Engineer for the Park Commissioners of Milwaukee, Wis., and erected in Lake Park of that city during the last few years. In designing these bridges Mr. Sanne was instructed to provide designs which should fulfil not only all engineering requirements, but should also be artistically worthy of the sites the bridges were to occupy. The several views of the completed structures which we publish will enable each reader to judge for himself in what measure Mr. Sanne has succeeded in securing these results. The photographs from which these views have been engraved were furnished us by Mr. Sanne, and from a paper read by the same gentleman at the meeting on July 6 of the Western Society of Engineers, we abstract the following brief description of the different structures.

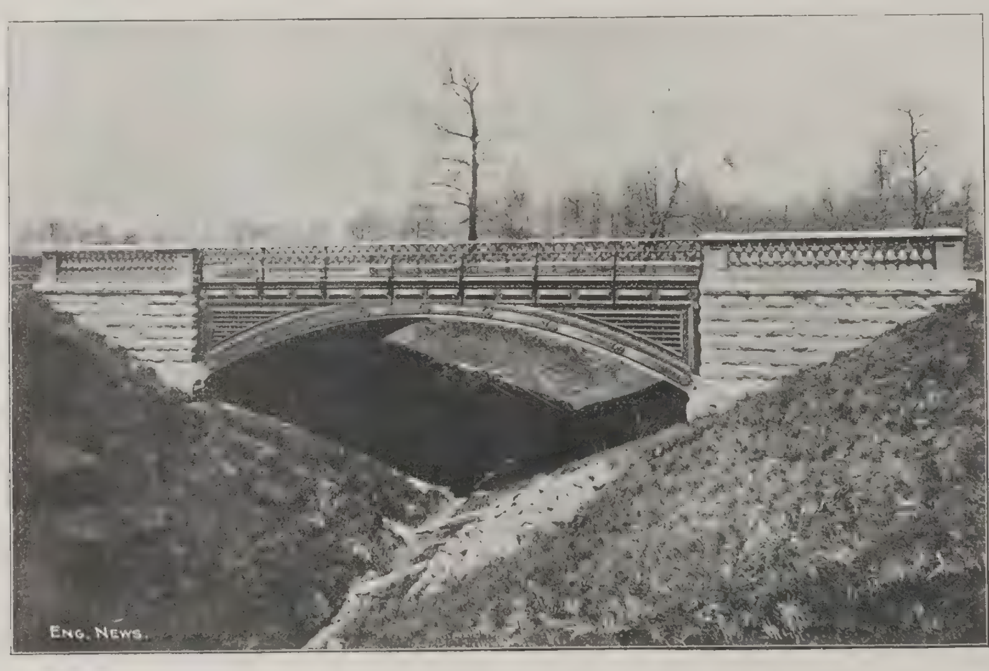

FIG. 2.—VIEW OF 50-FT. STEEL ARCH HIGHWAY BRIDGE, LAKE PARK, MILWAUKEE, WIS.

Fig. 1 is a side elevation of the smallest of the several structures, it being intended for pedestrians only. This bridge is composed of two 30-ft. and one 50-ft. plate girder deck spans. The girders are 30 ins. back to back of angles. This depth was considered the most effective one with regard to graceful appearance. The girders are placed 12 ft. 9 ins. c. to c., leaving a walk of 12 ft. clear width between railings. The bridge is supported by two bents of ornamental cast iron columns well braced. The abutments are of limestone masonry, with a hand railing of terra cotta on top of the coping. The cost of this structure was as follows:

Masonry and terra cotta railing	$1,398.45
Iron work	1,274.00
Total	$2,672.45

The second bridge shown (Fig. 2) is a 50-ft. steel arch, which carries the park driveway over a very picturesque ravine. It is composed of six 50-ft. steel arch ribs, with the front ribs shielded from view by a cast-iron ornamental cover. The four inner ribs are each composed of four 3 × 3½ × ⅜-in. angles, and one 18 ft. × 5-16-in. web plate, and the two outer ribs of four 3 × 3½ × 5-16-in. angles, and one 18 ft. × ¼-in. web plate. The ribs were calculated and constructed as arches with two hinges, and were figured for a live load of 100 lbs. per sq. ft. plus the dead load. The floor was figured for the same uniform live load, and in addition for a ten-ton road roller.

The roadway is 26 ft. wide resting on a floor support of I-beams and buckle plates; the roadway itself being composed of about 6 ins. of concrete, on top of which are laid 5-in. asphalt paving blocks. The sidewalks are 7 ft. wide, resting on I-beams, and are made of ⅜-in. cast-iron plates with diamond facing. The abutments are U-shaped, with very heavy buttresses for each arched rib. A terra cotta hand-railing is placed on the top of the coping. The cost of this bridge was as follows:

Masonry and terra cotta	$5,786.00
Iron work	4,265.65
Roadway floor and sidewalk	769.83
Total	$10,821.48

The third bridge, shown by Fig. 3, is a 35-ft. brick arch, which also spans a ravine. The ornamental parts of this arch were made of terra cotta, as well as the face stones of the arch proper. The arch is built of five rings of the best sewer brick, laid in Milwaukee cement. The faces of the spandrel and wing walls were laid with a very handsome brownish face brick. The sidewalks, 6 ft. wide, are made of concrete, and the roadway, 26 ft. wide, of macadam. An ornamental hand-railing of terra cotta surmounts the structure. The total cost of this bridge, which was let in one contract, was $10,449.

Bridges four and five were twin structures, and their general appearance is shown by Fig. 4. These bridges form the main entrance to Lake Park, and are located in the neighborhood of the most desirable and finest residence property in the city of Milwaukee. It was, therefore, natural that these structures should receive great care and attention in their design. After a careful investigation of the peculiarities of the location, with due consideration of economy and utility, it was decided that the most satisfactory solution of the problem would be the adoption of an arch bridge, with open spandrels, so as to obstruct the view over the lake as little as possible.

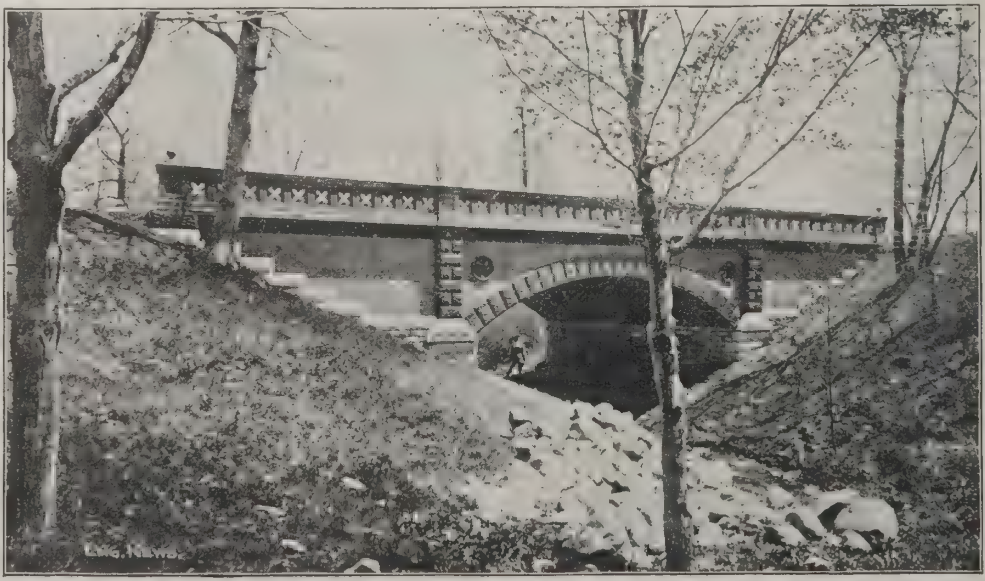

FIG. 3.—VIEW OF 35-FT. BRICK ARCH HIGHWAY BRIDGE, LAKE PARK, MILWAUKEE, WIS.

These bridges were started in September, 1896, but owing to some difficulty in getting the proper stones, the work was badly delayed and the stonework was not finished until the beginning of October, 1897. The foundations offered no particular difficulties, as the bottom consisted of a very solid clay ground upon which the footings could be laid directly. To get a better distribution of the load, however, a layer of 2 ins. of sand was put under the footing course. The allowed pressure at the ground was 2½ tons per sq. ft. The foundation course consisted of selected stones not less than 12 ins. thick, and the masonry above the foundation and below the surface of the ground was rubble. Above the surface of the ground ashlar masonry with rubble backing was used. Stretchers were not less than 18 ins. thick, and each course above the skewback was of the same thickness of 16 ins. Below the skewback the stones varied from 16 to 17 ins. in thickness. Practically all the stones had to be cut stones with 1 in. chisel draft. The walls were provided with weepholes well-filled with broken stones for the purpose of drainage, and the filling behind the walls was cinders.

The bridges were calculated as two-hinged arches for a uniform load of 100 lbs. per sq. ft. plus the dead load. The floor proper was designed to carry a concentrated load produced by a steam roller weighing about 16 tons. In the calculation of these arches the effect of temperatures was also considered. Neither lateral nor sway rods were used, but ⅜-in. gusset plates and cross struts were placed at each panel point. The posts were bolted to cast-iron shoes. The floor of the roadway and sidewalks is carried by I-beams, upon which rest buckle plates ¼-in. thick. The roadway was made of 4 ins. of the best Trinidad asphalt resting on a 4-in. layer of concrete. The sidewalks are of Atlas cement concrete.

The hand-railing is of steel and cast iron. Due allowance was made in this railing for contraction and expansion by putting the ends of the railing into a pocket chiseled into the stone railing for this purpose. The abutments were finished by a cornice 2 ft. deep, and on top of this was put a plain railing. These two parts were originally designed for terra cotta, but as the cornice and railing could be obtained in Bedford sandstone for about the same price as the lowest terra cotta bid, it was concluded to use the sandstone. On the top of the half octagon of the hand-railing is placed an ornamental lamp-post with five lights. The bridges are further ornamented by sculptured stone lions resting on heavy pedestals. The costs of these bridges were as follows:

Masonry, four abutments complete up to cornice	$14,977.64
Iron work, bridges proper, including iron hand-railing, buckled plates, lamp posts and guard rails	16,075.00
Stone railing and cornice	3,712.00
Asphalt floor for roadway, $2.50 per sq. yd.	1,177.56
Cement sidewalks, 14 cts. per sq. ft.	491.87
Electric and gas fixtures	138.90
Total	$36,572.97

THE WEST SUPERIOR COAL STORAGE PLANT OF THE LEHIGH VALLEY COAL CO.

By William R. Davis.[*]

(With two-page plate.)

A coal storage plant having several structural features of novelty and interest was built at West Superior, Wis., by the Lehigh Valley Coal Co., in the Fall and Winter of 1894-95. The plant consists of two steel buildings for anthracite, each 246 ft. in diameter, and 100 ft. high, and each with a capacity of 50,000 tons; a bituminous floor, with a capacity of 45,000 tons, and retail pockets for the local trade, Fig. 1. Bituminous coal cannot be piled to a greater height than 30 ft. in this plant—a precaution against spontaneous combustion—and is the only coal not stored under cover.

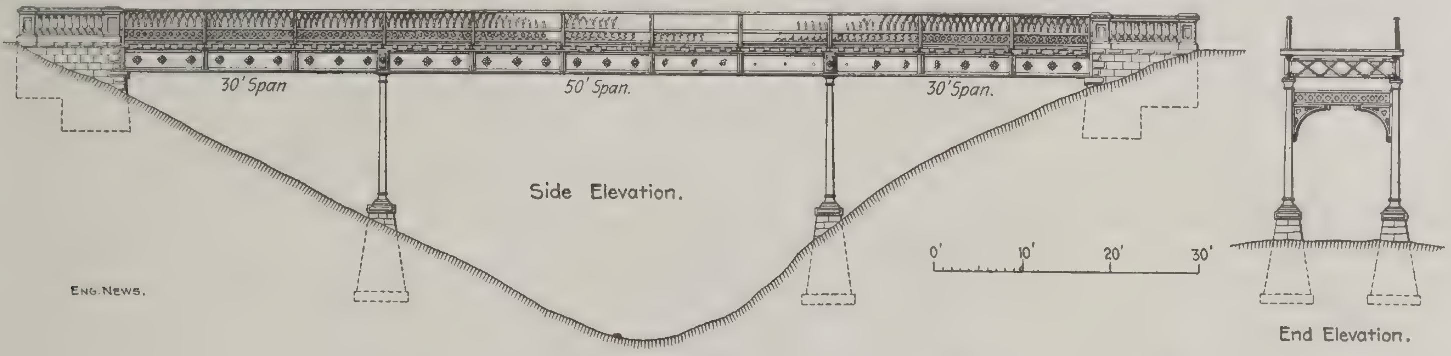

FIG. 1.—ORNAMENTAL PLATE GIRDER FOOT BRIDGE, LAKE PARK, MILWAUKEE, WIS.

The plant is located on Tower Bay Slip and through the local belt line railway has perfect shipping facilities. The wharf front consists of piling and cribwork. The original marshy ground on which the plant is built was filled in with sand, which was unloaded from scows by means of sand dredges. All foundations are supported on piles.

All coal is unloaded, put in storage and reloaded by machinery. Fig. 2 shows a sectional elevation of the anthracite plant. Coal from the company's mines in Pennsylvania, and loaded on boats at Buffalo, is delivered at the wharf in the open season from May to December. It is unloaded by automatic clam shell shovels of 2,000 lbs. capacity, furnished by the W. S. Bogle Co., of Chicago, and similar in most respects to those used in New York city. The towers carrying these shovels are of steel, 120 ft. high, and travel the full length of the wharf for use with either the anthracite or bituminous portions of the plant. The clam shell discharges into a hopper from whence the coal descends by gravity to the lower part of the ascending or trimmer trough. From this point it is handled by the Dodge system of endless chain conveyors. The trimmer trough has a movable bottom. Coal is first discharged through the open bottom at a point about 20 ft. inside the building, and the steel ribbon in the bottom is pulled ahead from time to time so that the coal will never fall more than a few inches.

The use of a steel roof compelled a novel departure in the form of the reloader. As usually constructed a single reloader lies between two piles of coal and operates into either at pleasure. In this plant the reloaders are pivoted at the center of each building (Fig. 3), and all coal is withdrawn through a cast-iron tunnel, below the floor. When the building is filled with coal the reloader is buried and lies directly over the axis of the tunnel. It is, of course, impossible to operate it then. The first coal, therefore, is removed through chutes suitably spaced along either side of the reloader, leading into the tunnel, after which the reloader is left uncovered and removes all that remains in the building. The coal discharged by either spouts or reloader into the tunnel is carried by a continuous chain conveyor extending along the tunnel and up an incline where it is passed through revolving screens into the pockets and loaded into the cars. The tunnel, which has an inside diameter of 7 ft., was cast with a body ⅞-in. thick, and ends 1¼ ins. thick. This has proved to be too light. It cracked in several places under full load, which is eccentric on account of an interior partition parallel and close to the axis of the tunnel. The cracks were patched and the tunnel braced immediately afterwards, however, and it has since given satisfactory results.

The Bogle Shovels have shown the following average capacity in anthracite for three shovels on a fair-sized cargo, from beginning to end of operation, viz.: For egg, 135 tons per hour; for stove, 165 tons per hour, and for chestnut, 185 tons per hour. The capacity of the anthracite plant has proved equal to that of the shovels. Each building can handle 185 tons per hour either into or out of storage when pushed.

The machinery for the entire plant, except that for the Bogle towers and the stationary engines, was furnished by the Link Belt Engineering Co., of Philadelphia, and the Link Belt Machinery Co., of Chicago, according to the designs of the Dodge Coal Storage Co., of Philadelphia, with Mr. Chas. Piez as chief engineer. The structural steel work was furnished by the Allentown Rolling Mills, of Allentown, Pa., with Mr. Frederick S. Guerber as chief engineer. The writer of this article was engaged on the design and was engineer of erection of the structural work. The erection of structural work and machinery was done by the Barnet & Record Co., of Minneapolis, Minn. The photographs by which this description is illustrated were taken by Mr. John A. Telner, Engineer of Erection for the Dodge Coal Storage Co.

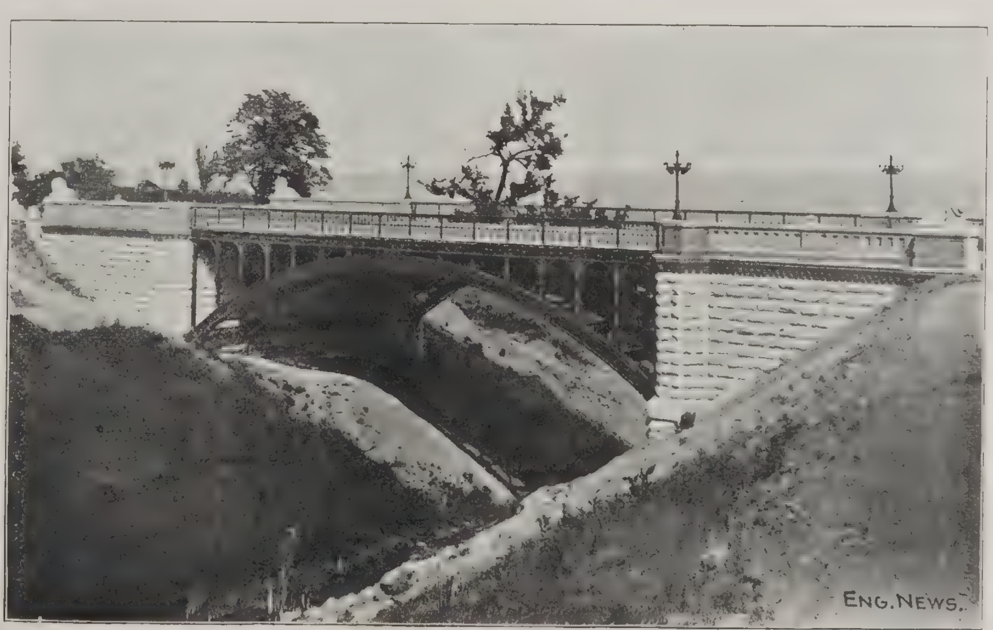

FIG. 4.—VIEW OF 87-FT. STEEL ARCH HIGHWAY BRIDGE, LAKE PARK, MILWAUKEE, WIS.
Oscar Sanne, Milwaukee, Wis., Designing Engineer.

Each building consists of 24 riveted trusses meeting at the center, which carry purlins covered with standard No. 22 corrugated iron. One truss, called the trimmer truss, and its opposite are made heavier and wider to carry the trimming conveyor and machinery, Fig. 4. The outer trusses were figured by graphic methods for the usual snow and wind loads under the different conditions of loading. It was required to design for safety with a view to rigid economy. To avoid the ambiguity attaching to the stresses when a central ring to which the trusses are riveted is used and secure a true three-hinged arch. There was designed a connection, believed to be novel and certainly original, which is shown by Fig. 5. It will be seen that the trusses are erected in four groups of six each. They are all alike until near the top pin, when a special "neck" brings the pins of each group to a level of its own. The plan in Fig. 6 shows how the two center trusses are straight and how the ends of the side trusses are bent. At the bend, cast-iron bearing blocks are used, as shown by the section in Fig. 6 to transmit the horizontal thrust from one side truss to the opposite one. The tongues and grooves are provided to prevent the possibility of undue distortion under excessive eccentric wind loads, and are used merely as an extra precaution.

Fig. 6 shows the working drawings of one group of necks. The others are similarly constructed. Separate pins are used for each pair of trusses, making three pins for each group, except the upper group, which contains the special trimmer trusses. In this case the truss narrows down to come on its bearing pin, but a stiffening member passes over the side trusses and down to two additional pins concentric with the other three (see Fig. 3), serving only to give added lateral stability to these trusses which were the first to be erected. The vertical space between the several groups was made as small as was consistent with freedom of erection. The thrust of the trusses is taken up by rods meeting in a heavy ring which lies outside the mouth of the tunnel and below the reloader.

In storage plants, as previously built in the east on the Dodge system, the coal had been heaped in piles which were perfect cones. In this plant, it was desired to save the outer space where the depth was small by using a retaining wall, as shown in Fig. 1, an arrangement which very much reduced the cost of the buildings.

---

[*] 1455 Washington Ave., New York, N. Y.

Mr. James M. Dodge, President of the Dodge Coal Storage Co., proposed the method here described, and has patented it.

The wall consists of special corrugated iron, No. 16, or 1-16-in. in thickness, with a pitch of 5 ins., and corrugations 1 in. deep, manufactured by the Cincinnati Corrugating Co., of Piqua, Ohio. This is supported by 4-in. 7-lb. steel beams spaced 2 ft. 11 ins. apart between centers, and each anchored by two ¾-in. diameter rods, which are fastened to a steel plate 36 ins. × ¼-in., standing vertically in a solid ring, fully spliced with lap joints, and with a radius about 20 ft. less than that of the wall. The construction is fully shown by Figs. 7 and 8. The pressure on the wall was assumed to be that given by Trautwine (p. 686, art. 6; p. 689, Rem. 4). The following table is compiled by the Link Belt Engineering Co., from Trautwine's formulas, which are in reality those of Coulomb. The figures are based on 27° for the angle of repose, the true figure for large piles, and 52.1 lbs. per. cu. ft. for the weight of coal in smaller sizes. The writer does not wish to be understood as indorsing the theoretical correctness of the formulas:

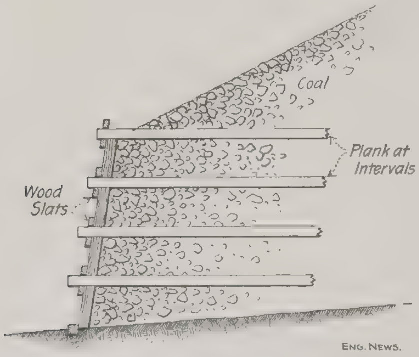

Fig. 10.—Sketch Showing Ordinary Method of Piling Coal.

Table Showing Pressure of Different Depths of Coal on Horizontal and Inclined Surfaces.

	Horizontal surface. Pressure		Sloping surface. Pressure.	
Depth, (d) in ft.	Total.	On lowest ft.	Total.	On lowest ft.
1	9.78	9.78	14.22	14.22
2	39.12	29.34	56.88	42.66
3	88.02	48.90	127.98	71.10
4	156.48	68.46	227.52	99.54
5	244.50	88.02	355.50	127.98
6	352.08	107.58	511.92	156.42
7	479.22	127.14	696.78	184.86
8	625.92	146.70	910.08	213.30
9	793.18	166.26	1,151.82	241.74
10	978.00	185.82	1,422.00	270.18
11	1,183.38	205.38	1,720.62	298.62
12	1,408.32	224.94	2,047.68	327.06
13	1,652.82	244.50	2,403.18	355.50
14	1,916.88	264.06	2,787.12	383.94
15	2,200.50	283.62	3,199.50	412.38
16	2,503.68	303.18	3,640.32	440.82
17	2,826.42	322.74	4,109.56	469.26
18	3,168.72	342.30	4,607.28	497.70
19	3,530.58	361.86	5,133.42	526.14
20	3,912.00	381.42	5,688.00	554.58

Note.—Surface horizontal: Total pressure for depth (d) = 9.78 d^2; pressure on lowest foot = 9.78 (2d — 1). Surface sloping, at angle of repose: Total pressure for depth (d) = 14.22 d^2; pressure on lowest foot = 14.22 (2d — 1).

The anchor rods were so spaced as to give nearly equal moments at the points of attachment and between. The working stresses were assumed to be 16,000 lbs. per sq. in. for both coal and wind loads. The horizontal wind pressure was assumed to be 30 lbs. per sq. ft. The only connection of the wall with the trusses was at the top of the beams, which merely rested against the strut at the hip, to take the wind reaction. It was thus intended to make it impossible that any of the coal pressure should be carried into the trusses, a precaution so that a failure of the wall might not involve a more serious failure. When storing coal, the band is first imbedded before any pressure comes on the wall, and, as shown in Fig. 1, the anchor band is well within the conical portion of the pile which gives no pressure to the wall. The reader will notice the similarity between this method and that long in use in which the wall is built of planks anchored by other planks running back into the face of the pile, as shown in Fig. 10. When the anchor band was erected it swung lightly upon the ¾-in. anchor rods without other support. To avoid undue strains from the weight of the coal, legs were provided about 8 ft. apart resting upon steel plates on a wooden sill, pivoted to swing clear for the reloader. This wall and the rest of the structural work has been entirely satisfactory, and no weak points have developed after three winters' service.

THE SHEARING STRENGTH OF RIVET STEEL.*

Five years ago the use of steel for rivets in high-grade boilers, stand-pipes and structures was considered doubtful practice by many engineers, and wrought iron rivets were used long after wrought iron plates had been displaced by steel. Steel rivet material of that day was unreliable and lacked the toughness and uniformity which is essential for standing the abuse of ordinary riveting operations. Improvements in manufacture have produced a steel rivet bar, which for toughness, uniformity and reliability, in fact for everything except the range of temperature allowable in riveting, is the equal of the best iron rivet.

Present practice in designing joints uses values of the shearing strength of steel based upon experiments made several years ago. The data frequently quoted are from experiments made in England by Prof. A. B. W. Kennedy in 1885. The shearing strength of these steels varied from 67 to 83% of the tensile strength. From these and other tests on the earlier structural steels, the ratio of the shearing strength of rivet steel to its tensile strength has been assumed to be 80%, and the ratio of this shearing strength to the tensile strength of the plate used in the joint, 75 to 83%.

As a contribution to the knowledge of this subject, the results of a series of tests made in the Laboratory of Applied Mechanics of the University of Illinois are presented. The tests first described were made by the different class divisions as regular laboratory work, and the later tests directly by Mr. C. V. Seastone, assistant in the Laboratory of Applied Mechanics. Three sizes of four varieties of rivet material were used, and tests were made both for single shear and double shear.

Four varieties of material were tested: 1. The Victor boiler rivet steel, manufactured by the Champion Rivet Co. of Cleveland, Ohio; 2. Best Boiler rivet steel, manufactured by Sternbergh & Son, Reading, Pa.; 3. Structural rivet steel (said to be Bessemer steel), manufactured by Sternbergh & Son; and 4. Best rivet iron, manufactured by Sternbergh & Son. Three sizes of each of these makes were used, ½, ¾ and 1-in. diameter. The rivet rod fitted the holes in the apparatus so accurately that it was not found necessary to turn the rods down.

The determination of the phosphorous and sulphur of the rivet material made by Prof. S. W. Parr resulted as follows:

	Per cent.	
	Phosphorous.	Sulphur.
Victor steel	0.025	0.043
Best boiler steel	0.011	0.031
Structural rivet steel	0.041	0.053
Wrought iron	0.058	0.000

The accompanying cut shows sections of the apparatus used for making the shearing tests. The apparatus for single shear, shown at a, consisted of two bars with accurately drilled holes through which the test pieces passed. A bolt through the slotted holes above the test piece and one through the holes below it, held the bars firmly so that the shearing planes remained together. Tests showed that the friction between these plates was small. The length of the bars (28 ins.) reduced the eccentricity of the pull to a very small amount.

TABLE I.—Comparison of Shearing and Tensile Strengths of Rivet Material.

	Tension.				Single shear.		Double shear.	
Diameter.	Ultimate strength, lbs.	Elastic limit, lbs., per sq. in.	Elongation in 8-in., %.	Reduction of area, %.	Ultimate strength, lbs., per sq. in.	Ratio of shear to tension, %.	Ultimate strength, lbs., per sq. in.	Ratio of shear to tension, %.
Victor Boiler Rivet Steel.

Best Boiler Rivet Steel.								
½-in.	48,700	35,300	33	62	38,550	79.1	39,250	80.6
¾-in.	47,000	28,650	36	68	36,200	77.0	36,300	77.2
1-in.	49,330	30,600	32	70	36,100	73.2	36,200	73.4
Structural Rivet Steel.								
½-in.	55,400	37,700	26	70	43,400	78.3	42,100	76.0
¾-in.	55,900	37,350	29	64	41,700	74.6	41,900	74.9
1-in.	53,600	35,500	29	71	38,000	70.9	38,600	72.0
Wrought Iron.								
½-in.	49,600	37,750	25	46	40,200	81.5	38,200	79.5
¾-in.	50,200	31,200	38	48	38,600	77.0	39,100	79.8
1-in.	48,400	32,000	33	52	35,200	72.8	36,400	75.2

The apparatus for double shear, shown at b, consisted of two middle bars ⅝-in. thick and an upper and a lower bar each 1 in. thick. The upper bar was fastened to the two middle bars with a 1½-in. bolt, and the test pieces passed through accurately drilled holes in the middle and lower bars. A bolt through a slotted hole in the middle and lower bars held them firmly together. The bolts and the stiffness of the middle bars prevented any bulging or buckling of the bars during the process of shearing.

The bars were tool steel of 80,000 lbs. tensile strength. The upper and lower bars were placed in the grips of the 200,000-lb. Olsen testing machine and tension applied. Little perceptible distortion took place in the test holes of the apparatus. The usual tension tests of the rivet material were also made. The steel rods were bent cold flat on themselves without showing flaws, and a 1-in. Victor steel rod was tied in a close knot by cold bending.

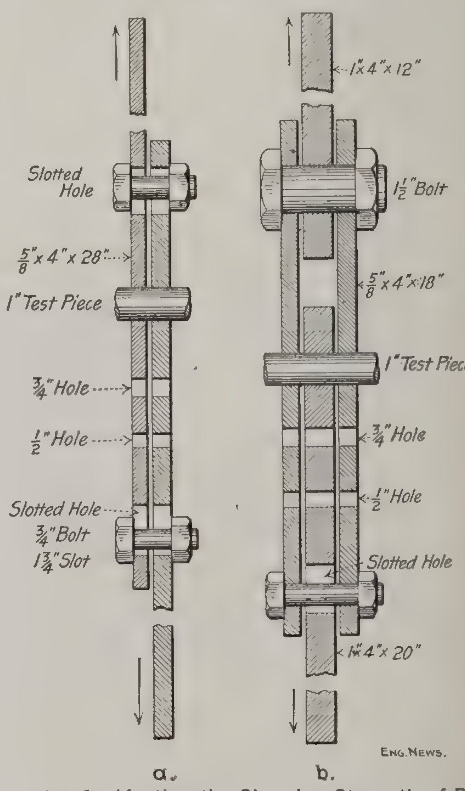
The sheared pieces are specially noticeable for the indentation which takes place after the elastic limit is reached. The shoulder or indentation was as much as 10% of the diameter, and increased with the diameter of the test piece. The bending action was slight and was scarcely noticeable on the compressed side. An examination of the pieces during and after the tests showed that this method of testing largely eliminates the flexural effect upon the rivet and hence is not subject to the criticism sometimes made upon shearing tests.

The average of the results of the tests are given in Table I.

It would be interesting to know why the ratios for the small rivets are higher than those for the large. If bending entered into the results, the smaller rivets would have the smaller ratios. The table shows that the tensile strengths of the several sizes average almost exactly the same. To find whether the variation was caused by softer material in the large rivets, four test pieces of the larger sizes were turned down to ½-in. and tested for double shear. The results gave ratios within 1% of the ratios in Table I. for ½-in. rivets of the same material. It seemed probable that the increased bearing stresses in the larger size—the thickness of plate remaining the same—might be the cause, and the larger indentation in the larger test pieces corroborated this view.

To determine the effect upon the shearing strength of increasing the bearing stress, an apparatus for single shear was then constructed having the shearing bearing stresses 1⅔ times the former ones. The shearing ratio of the ½-in. rivets was decreased nearly 4% and the 1-in. 1¼%. As even with this apparatus, the ½-in. rivet did not reach the usual bearing stress, it is quite probable that the shearing ratio would be still smaller for the usual conditions of joints. These results tend to show that the amount of the bearing stresses affects shearing strength, the latter decreasing with an increase in the former. They, at least partially, explain the higher ratios for the smaller rivets in Table I.

To determine the effect of the hardness of the shearing plate upon the shearing strength of the rivet material, an apparatus for single shear was constructed with ⅝-in. bars of 56,000-lb. mild steel. With this apparatus not more than one or two rivets could be tested in a single hole, for the distortion of the plate became quite marked. The results are given in Table II. It will be seen that the shearing ratios have been increased about 4.6% over the corresponding values in Table I. This increase in the ratios



Apparatus for Testing the Shearing Strength of Rivet Steel.

---

*Abstract of a paper by Arthur N. Talbot, Professor of Municipal and Sanitary Engineering. Reprinted from "The Technograph, No. 12, University of Illinois, more than neutralizes the decrease found by reducing the bearing areas to the values used in practice as discussed in the preceding paragraph.

TABLE II.—Tests to Determine the Influence of Soft Plates on the Shearing Strength of Rivets.

Material.	No of tests.	Ult. shear. strength.	Ratio shear to tension.	Inc. in ratio.
Victor rivet steel, ½-in....	1	41,500	86.3	6.3
Wrought iron, ½-in.......	1	41,600	83.9	2.4
Structural rivet steel, ½-in.	1	46,200	83.4	5.1
Victor rivet steel, ¾-in....	2	41,000	82.1	6.4
Wrought iron, ¾-in.......	2	40,400	80.5	3.5
Wrought iron, 1-in.......	1	37,000	76.4	3.6
Best boiler rivet steel, 1-in.	1	38,550	78.2	5.0

It may be considered, then, that for the usual bearing stresses, with mild steel plate and soft steel rivet metal, the ratio of shearing strength of the rivet to its tensile strength is less than that generally quoted, 0.80, and that 0.75 is a more probable value. It seems to be shown, also, that an increase in the bearing area of the rivet will give increased shearing strength to the rivet. The use of hard steel plates with soft steel rivets likewise decreases the shearing strength of the rivets.

In all the preceding discussion, comparison of the shearing strength of the rivet has been made with that of the tensile strength of the rivet itself. The ratio of the shearing strength of the rivet mètal to the tensile strength of the plate will be lower yet. For 48,000-lb. tensile strength rivet metal and 56,000-lb. steel plate, the ratio is 0.65; and for 55,000-lb. rivet metal and 62,000-lb. steel plate, it is 0.68. These results indicate that the ratios commonly used in designing joints (the shearing strength of the rivets equal to three-fourths or five-sixths of the tensile strength of the plate) are too high and hence that rivet spacing should be made closer. While these conclusions are based upon results found beyond the elastic limit, it does not seem possible to obtain comparative data within that limit.

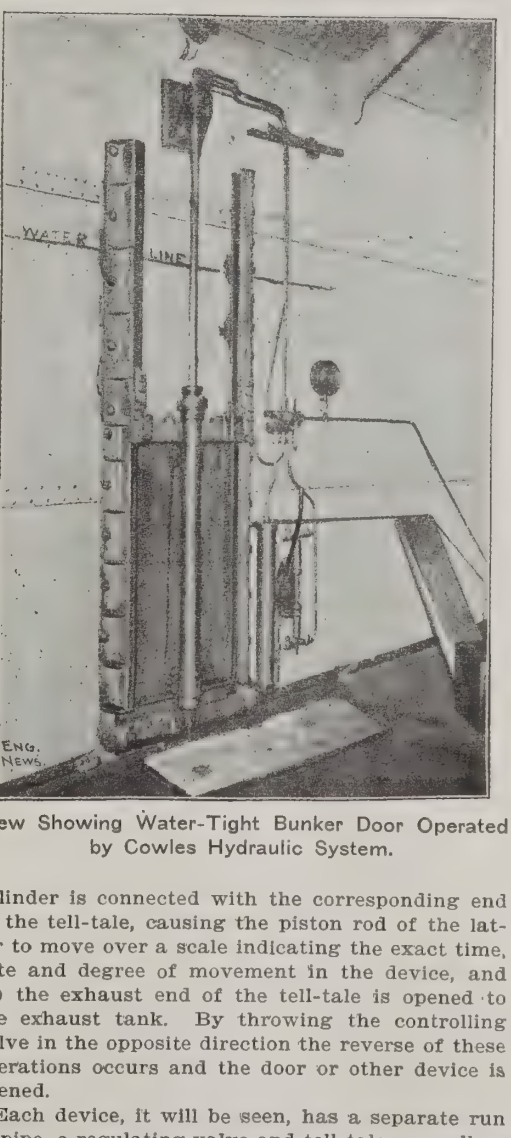
The writer does not accept the statement sometimes made that the shearing strength of rivets has little influence upon the strength of the joint, on the ground that the friction of the plates will hold the tensile stress well up to the elastic limit of the plate; for he does not think that it has yet been conclusively proved that the friction is so great. Tests made in the Laboratory of Applied Mechanics on riveted joints show that slipping occurs at or below the usual working stresses. The average of 22 double-riveted lap joints, hand riveted, gave 4,900 lbs. per sq. in., the maximum being 9,500 and the minimum 3,000. The average of 16 double-riveted butt joints, machine riveted, gave 9,000 lbs. per sq. in., the maximum being 13,000 and the minimum 5,500 lbs. Tests made elsewhere indicate that slip occurs at or below the usual working stresses, although some show much higher results. At any rate, it is not safe to assume that friction between the plates will prevent shearing stresses in the rivets, and with this view the shearing strength of rivet material becomes an important matter.

THE COWLES SYSTEM OF WATER-TIGHT BULKHEAD DOORS FOR THE U. S. CRUISER "CHICAGO."

One of the novel features of the reconstructed cruiser "Chicago," which will shortly be turned out of the Brooklyn Navy Yard ready for service, is the system of hydraulicly operated water-tight bulkhead doors, designed by Naval Constructor W. B. Cowles. To the layman the number of bulkhead doors, hatches and valves in the modern warships, which have to be closed often almost instantly in certain emergencies, is hardly appreciated. For example, the battleships "Indiana," "Massachusetts" and "Oregon," of the United States Navy, each has 272 water-tight compartments, with 354 doors and hatches and 294 valves, altogether 648 openings which have to be closed quickly under certain conditions. To close these openings and bring the cellular structure of the ship into operation in the case of an emergency requires, it is stated, the work of 110 men, exclusive of officers. It is easy to see, therefore, how in certain cases it may be practically impossible to bring all these safety devices into operation no matter how well disciplined the crew may be.

The cardinal ideas of Mr. Cowles' invention is to insure greater certainty of operation by taking it out of the hands of many persons and concentrating it by mechanical means into the hands of one stationed at a convenient central point. The problem involved several factors besides that of certain and safe central control of the valves and doors located in widely scattered positions. It was necessary to provide that the central control should involve no harm to the men whose duties might be in the various compartments by closing the avenues of escape independent of their will. Further, it was necessary that the doors should be such as would close against the pressure of water, or, in case of the bunker doors, through coal.

Two methods of central control, known as the "double line" and the "single line" systems, are employed. In the "double line" system the primary circuit consists of two cylinders with their pistons and rods connected by a double line of small piping in which is placed a controlling valve which governs the admission and release of pressure to and from the circuit and between the cylinders. The cylinders may be of any convenient dimensions, but while they are not necessarily duplicates, the corresponding ends must have equal piston displacements. One cylinder, called the power cylinder, is placed with its piston rod in connection with the device to be operated, for example, a bulkhead door, as shown by the accompanying illustration. The other cylinder, called the tell-tale, is placed at the point from which it is desired to operate the device. Operation is brought about as follows: The controlling valve is moved to the proper point, say, to close the door, when three things take place simultaneously: (1) Pressure is admitted to one end of the power cylinder causing its piston to move and close or otherwise shift the device; (2) the exhaust end of the power cylinder is connected with the corresponding end of the tell-tale, causing the piston rod of the latter to move over a scale indicating the exact time, rate and degree of movement in the device, and (3) the exhaust end of the tell-tale is opened to the exhaust tank. By throwing the controlling valve in the opposite direction the reverse of these operations occurs and the door or other device is opened.



View Showing Water-Tight Bunker Door Operated by Cowles Hydraulic System.

Each device, it will be seen, has a separate run of pipe, a regulating valve and tell-tale, as well as individual operating cylinders, and can be operated by itself alone. The regulating valves and tell-tales are all located in one place, namely, the central station, and 120 sets may be placed on an operating board 40 × 80 ins. in size, projecting not more than 10 ins. from its face. The emergency attachment consists of a primary circuit, so arranged and connected that its power piston will simultaneously throw into the closing position any desired number of the controlling valves in the central station. The power cylinder of the emergency circuit is in the central station, but its tell-tale and controlling valve are placed at the point where the danger to be guarded against will most naturally first be discovered. The number of groups of central station valves controlled by emergency circuits can obviously be made as great or as small as desired.

To complete the power transmission system only one other device is necessary, which is the liberty valve. This is placed near the door or other device to be operated and consists of a spring controlled valve arrangement which may be operated by a person liable to have his escape shut off by the operator at the central station or at one of the emergency stations. The person in danger by simply throwing the liberty valve shuts the power off and thus arrests the closing of the door which it governs until he can escape, when the spring restores the normal condition and the door closes behind him.

The foregoing describes the "double line" system quite clearly. The "single line" system, which is the one employed on the "Chicago," works upon the principle of superimposing one pressure on another in the same pipe to obtain at will two separate and distinct ways of operating and controlling a device at a distance. This is done through a single pipe in combination with suitable valves, connecting pipes, and a power cylinder, much in the same general manner as in the "double line' system, but with one run of pipe in common for all devices instead of individual runs for each. There is, however, no central station such as there is with the "double line" system. Individual operation of a device is controlled by the liberty operating valve at the device, but the emergency operation of all devices simultaneously is controlled by a controlling valve and tell-tale placed at some central point.

The particular installation on the "Chicago" consists of eleven vertical sliding doors, all in the engine and boiler compartments, made of ¼-in. steel plates with vertical angle iron stiffeners and with manganese bronze plowshares to force a way through coal. The power cylinders for each door are made of seamless brass tubes. The system is operated by a steam accumulator and duplex pump of the Worthington type, which are placed under the protective deck. The hydraulic main is 2 ins. in diameter, reduced in suitable steps. The emergency gear consists of a power cylinder with a 4-in. stroke, operating the by-pass cock on the accumulator and a corresponding tell-tale and controlling valve in the conning tower, connected by a ⅛-in. pipe and forming a primary circuit. Ingenious devices are provided to tighten the doors at side and bottom. The side tighteners consist of traveling rollers held between a wedge track and a wedge bar, each of these latter being the full length of the door. The wedge track is secured permanently to the door, and the wedge bar rides with the door throughout its travel, except during the short tightening interval at the closing end of the stroke, within which the wedge bar is held stationary on the guide, thus causing relative movement between the wedge track and wedge bar on the rollers. This movement presses the wedge bar out against the guide lip, and the wedge track, with the door and seating strip, in against the seat.

Tests which have been made show the ability of bulkhead doors of this type to close against a head of water and also through piles of coal. Their operation and control are also proven to be satisfactory. The chief objection which has been raised to the system is that it adds another to the already large number of complex mechanical devices of the modern war ship.

NOTES AT DETROIT.

The city of Detroit claims the title of "the convention city," and the fact that it had 150 conventions last year seems to make good this claim. It has a special organization, the Detroit Convention and Business Men's League, whose object is to invite and secure the attendance of such gatherings, and to arrange for their entertainment. This is done in order to advertise the city and spread its reputation, although the direct advantage to trade seems to be doubtful. Mr. O. A. Bierce is Secretary of the league.

The city has an area of 29 square miles, a frontage of 9.2 miles on the Detroit River, and has a population of about 300,000. It is substantial and attractive in appearance, having wide, well-paved and remarkably clean streets, fine buildings, and an atmosphere free from smoke, in spite of the fact that the city has numerous manufacturing establishments. A system of boulevards surrounds the city, and there are numerous large and small parks, while many of the streets are lined with trees. Woodward Ave. is probably one of the finest residence streets in the country. There are 235 miles of paved streets, exclusive of 11 miles of macadamized boulevards, and the paving includes 20 miles of asphalt and 20 miles of brick. Where car tracks are laid on streets having asphalt paving, brick is laid between the rails and tracks, the asphalt being brought close against the outer rails. At present there is a squabble between the City Council and the Board of Public Works as to the use of brick, the former favoring a ten-year guarantee, and the latter favoring the selection of brick by test. Under the present system the brick submitted by contractors are put through the rattler and absorption tests. Much of this class of paving requires repair in four or five years, and the requirement of a ten-year guarantee would, it is said, bring the cost up to that of asphalt. In the meantime but little brick paving is being laid. Both red and yellow brick are in use, and it is proposed to lay several kinds of brick on one street for actual observation as to the relative wear.

The city has 175 miles of main sewers and 276 miles of lateral sewers. The sewer system is now practically complete, and but little work is being done on extensions. Mr. Henry D. Ludden is City Engineer, which office includes also that of engineer for the Board of Public Works.

There are 167 miles of street railway and 71 miles of suburban lines, while 127 miles of suburban line are now under construction. All these are operated by electricity. In the paved streets grooved rails are used, and steel ties are used to a limited extent under heavy girder rails on concrete, there being only four ties to a rail. The cars are noticeable for their cleanliness and the good condition in which they are kept. There are two long electric lines running in competition with railway service; the Rapid Ry. to Mount Clemens, 15½ miles, and the Detroit, Ypsilanti & Ann Arbor Ry., to Ann Arbor, 38 miles. Mr. J. D. Hawks, M. Am. Soc. C. E., is Engineer and Manager of this road. Double-track cars, fitted with air brakes, are used on these lines, and baggage is carried in separate cars on the former and in combination cars on the latter.

The electric light plant is owned and operated by the city, and supplies 1,800 arc and 3,500 incandescent lamps, most of the former being mounted in groups on the tops of tall towers of iron framework. The report of the electric light commission, which has just been issued, puts the present cost of $83.50 per arc lamp, which the commission compares with a probable cost of $90 if the work was done by contract at this time. The city's water supply system dates back to 1824, and has been in charge of a water commission since 1852. There are two 6-ft. intakes and one 5-ft. intake, and three 42-in. force mains. The water is pumped direct through a distribution system of 526 miles of 2-in. to 45-in. pipe at preshure of 10 to 35 lbs. The pumping plant consists of four engines, three of which have a capacity of 24,000,000 gallons, while the other has a capacity of 35,000,000 gallons per 24 hours. There are 3,002 fire hydrants, 549 fire cisterns, and 73 hydrants in the auxiliary fire system. Meters were first introduced in 1889, and there are now 5,392 in service, which metered 19% of the entire amount pumped by the engines in 1897. The Fire Department has 21 steam engines, a fire-boat, 6 chemical engines and 417 men, while its equipment also includes 445 miles of fire alarm telegraph, 356 alarm boxes, and 581 reservoirs.

The Deep Waterways Commission, appointed by the government to investigate and report upon the proposed waterway connecting the Great Lakes with the Hudson River, has its headquarters in Detroit. This commission is composed of Mr. Alfred Noble, Mr. George Y. Wisner and Mr. G. W. Rafter, all members of M. Am. Soc. C. E. Parties are now in the field surveying routes from Lake Ontario and the Hudson River, one of which is proposed to utilize Lake Champlain as a part of the waterway. The preliminaries for the design of the lock gates are in charge of Mr. Henry Goldmark, M. Am. Soc. C. E., who has made extensive investigations as to the different forms of construction used in this and other countries. It has practically been decided to use iron gates, with a single skin, these gates being used in pairs. The full report of the commission will probably not be made until near the end of next year.

Detroit is a very important railway center, both for through and terminal traffic. It has a freight belt line and extensive freight yards, and in the city are three passenger stations for the twelve railways centering at this point.

The Michigan Central Ry., like the Grand Trunk Ry., has its own terminal station, and does not use the union station. Its general offices are in the station building. On this road a number of experiments with rail joints have been made, and it is now trying the Long and Fisher joints to a small extent. It has also 20 miles of track laid with a base-support joint, devised by Mr. A. Torrey, the Chief Engineer, in which a piece of inverted 65-lb. rail is placed under the ends of the 80-lb. track rails and secured by two, or in some cases three U-bolts, which pass under the inverted rail and have their ends secured by nuts above the flanges of the angle bars. This requires no lowering of the joint ties, as in joints having bridge plates which rest on these ties, and though the lowering is made light of by manufacturers of joints of the "bridge" type, Mr. Torrey finds that it is the cause of considerable trouble in track work. An experiment is also being made with short bars having studs on the ends, the distance between the studs being 1-32-in. less than that between the bolt holes. These clamps are put on hot (are on each side of the rail) and are covered by the angle bars. Notches cut across the rail heads by a Bryant saw, to represent joint spacing, have resulted in a rapid cutting out of the rail beyond the joint. Mr. Torrey is a believer in continuous rails, and has an experimental rail length of 500 ft. put up with turned bolts in drilled holes. The maximum expansion of this length is 4½ ins. The road has now 80% of its main track laid with 80-lb. rails, and 32-in. four-bolt joints are taking the place of the old 38-in. six-bolt joints. Rails for relaying have their ends cut off and are then laid upon a bed in lots of 80 rails, and numbered with chalk. A man then takes a special caliper and a box of 80 slips or "dominoes," and calipers the height of head at each end of each rail, marking the heights and the number of the rail upon a domino. When this is done he sorts out 60 of his slips, or "plays dominoes" with them until he has matched rail ends of the same height. He then re-numbers the dominoes in this order, and also numbers the rails in the same order with paint. A loading machine then loads the rails on the car, putting No. 60 first, so that in unloading on the track No. 1 will be the first rail handled. In this way good joints are secured at small cost. The 20 rails which do not match well go into the next lot.

Detroit is also one of the important lake ports, and the traffic through the Detroit River in 1896 included 33,290 vessels with an aggregate gross tonnage of over 35,000,000 tons. The traffic includes a great variety of craft, from small sailing and steam vessels and barges to the modern freight and passenger steamers of over 400 ft. in length, and the immense steel barges which some of the freight steamers tow as consorts. Among the most interesting vessels are the "Northwest" and "Northland" of the Northern Steamship Co., which resemble the Atlantic liners, and run from Buffalo to Duluth, an inland route of nearly 1,100 miles. Other notable craft are the fast sidewheel steamers of the Detroit & Cleveland Navigation Co., which runs from Detroit to Mackinac and Cleveland. These are driven by two-cylinder, compound vertical beam engines, of the type which has so long been a feature of American marine engineering. The dimensions of the "City of Mackinac," built in 1893 for this line by the Detroit Dry Dock Co., are as follows:

Length over all	275 ft. 0 ins.
Beam	38 " 6 "
Width over guards	68 " 11 "
Depth	15 " 0 "
Gross tonnage	1,736 tons
Cylinder, h. p.	42 × 88 ins.
Cylinder, l. p.	66 × 132 "
Boilers, two double-ended	12 × 19⅝ ft.
Speed, in regular service	18 miles per hour
Paddle-wheels, diameter	25 ft. 7 ins.

The manufacturing industries of the city are numerous and varied, including steamships, marine and stationary steam engines, gas engines, salt and soda-ash, railway cars, stoves, paint, sulphite fiber, and a multitude of smaller industries. There are in all about 2,000 manufacturing establishments, employing about 50,000 persons. At Wyandotte, about 12 miles down the river, are the remains of what is said to have been the first Bessemer steel plant established in this country. According to local accounts, a Detroit man went to England to negotiate with Bessemer, but the latter declined to make any agreement, and the former then obtained employment in Bessemer's works as a sand shoveler. Having learned the secret of the process he returned to this country, and, about 1860, established the Wyandotte plant, where steel was made, plates were rolled and a ship was built of these plates.

The Detroit Dry Dock & Engine Works Co. has a dry dock and shipbuilding yard at Wyandotte and another dry dock and an engine works in Detroit. The members of the American Society of Civil Engineers visited both plants, and examined the steel freight steamer "Troy," 425 ft. long, recently launched by the New York Central R. R. Its single screw will be driven by a quadruple expansion engine, supplied with steam by Scotch boilers, carrying 220 lbs. pressure. Considering the comparatively short runs, however, it is questionable whether there will be sufficient economy in fuel to compensate for the increased cost and complication of the engine. In this ship even the deck houses are of steel plating, and a somewhat peculiar arrangement is an anchor protruding from the stern. A portable pneumatic riveter was used for much of the work, especially for countersunk rivets in the deck plating, a pneumatic hold-on being applied underneath. A pneumatic chipping chisel cuts off the slight projection of the rivet above the plate, and it is then smoothed down by the riveting hammer. Steamers, engines and boilers for the Klondike service are also being built. At the shipyard is a drilling machine which is held up to its work by magnets, and the boilers are fitted with a very simple but effective smoke consumer, designed by the superintendent of the yard. It consists of a sliding and a fixed grating the whole size of the furnace door, and by regulating the admission of air above the fire by this damper, smoke can be entirely prevented. This was shown by opening and closing the damper, and the consequent disappearance or appearance of smoke from the stack. At the engine works is a shaft which was bought for iron, but which on being heated and put under the hammer broke with a fracture that showed simply a mass of granules or crystals which could be rubbed apart in the hand.

The Detroit Bridge & Iron Works is not now very busy in the shops, but has some large plate-girder through span having the ends rounded for the sake of appearance. These are for the Paragould Southeastern Ry., of which Wm. H. G. Kelly is the Engineer. This firm built most of the spans of the new Grand Trunk Ry. bridge at Montreal, which has been described in our columns. It has completed the erection of all the spans except the channel span, which is the longest. Owing to the headway required under this span a shallow floor was necessary, and this consists of transverse 24-in. 100-lb. I-beams, placed close together and covered with a plate to which the track rails will be bolted. The erection of the new trusses is done from a traveler like an inverted U which straddles the old tubular spans, the horizontal top member resting on trucks which run on rails laid upon the top of the tube. Several of the miter-cutting and shearing machines in the shops are mounted on turntables, so that they will cut work at any angle, thus avoiding the trouble of swinging long angle iron, etc., at an angle to the machine. Compressed air riveters and hoists are largely used, the latter having a valve devised by the shop foreman to regulate the admission of air according to the load, and so obtain a uniform speed of hoist. Railway turntables, with a pedestal bearing of turned conical rollers between planed and finished plates, are a specialty of this firm, and were described and illustrated in our columns some time ago.

The Detroit Graphite Manufacturing Co. has supplied nearly 8,000 gallons of its gray paint to the Navy Department for painting our warships the present service color, and considers that it is entitled to some credit for thus making the ships so nearly invisible that the Spanish gunners could not hit them. The company's paint is also specified by the War Department for the guns, gun carriages, etc., of the coast defenses. The viaduct of the Detroit Union Station Co. crossing a number of freight and switching tracks was painted with the graphite paint in 1893, and shows no signs of rust or deterioration, although it is constantly subjected to the smoke and gases from engines standing or passing under it. On one of the columns which has been damaged by a derailed car, the broken edges of the paint are pliable and tough, and the rust on the part where the paint has been knocked off has not spread under the paint. This paint is used extensively for bridges and structural iron work, and also for cars, gas tanks, boilers, smokestacks, etc.

The Frontier Iron Works are now making a specialty of gas engines, as the number of engine works established by shipbuilding works has materially reduced their former business in marine engines. Single-cylinder vertical engines are built of from 1 to 10 HP., and double-cylinder horizontal engines are used for powers of 10 to 100 HP. The special feature of these latter engines is their steadiness of running, which makes them well adapted for electric light plants, and we shall shortly illustrate and describe one of these engines.

The Griffin Car Wheel Co. has its parent plant at Detroit, with branches at Chicago, St. Paul, Denver and Tacoma. This company is distinct from the New York Car Wheel Co., which also operates the Griffin patents and has plants in the eastern states and in Europe. The Detroit plant has a capacity of 250 wheels per day, a large majority being of 33 ins. diameter. A bottom-pouring ladle is used, the 2½-in. hole in the bottom being opened or closed by a graphite plug on a rod in the ladle, which is operated by a lever. This device, which is patented, ensures the pouring of clear metal and the exclusion of dross. Each ladle holds a little more than enough iron for a wheel. The wheels are kept in annealing pots for five days. Street car wheels are a specialty, and these have curved spokes. A great source of trouble is the variety of tire and flange sections demanded for these wheels, there being no standard, as in railway wheels. This lack of uniformity results in considerable expense for chills. General castings for locomotive and bridge work, etc., are also made, and for specially hard metal, steel rail scrap is melted with the iron. An unusual system of accounting is in force here, under which the books are closed and balanced for profit and loss every month.

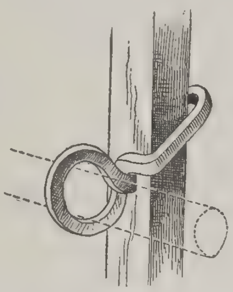
The Michigan-Peninsular Car Co. has two separate car works and a rolling mill, employing in all some 4,000 men, and turning out about 100 freight cars per day. The north works (or the old Penisular Car Works) have a capacity of 52 box cars per day, and have built 54 flat cars in a day. Tracks with turntables at the intersections are laid through the yards and buildings. In the machine shops are several multiple drills, some with six drills for drilling arch bars for trucks, and one with eight drills for miscellaneous work. Two men work at this latter machine. Wheels are pressed on their axles by a 50-ton hydraulic press. There is one foundry for axle boxes and miscellaneous work, and another for car wheels. The latter has a capacity for 400 wheels per day, and is equipped with the Whiting system of cranes and trolleys to handle the flasks, etc., and to carry the wheels to the annealing pits, where they remain for from three to five days. There are four regular cupolas, and a fifth for testing work.

In the woodworking shop the wood passes forward all the time from machine to machine, until it leaves the further end of the shop ready for the erecting shop. In this latter shop separate gangs of men attend to setting up the "bottoms" or underframes, the floor, side framing, sheathing, roofing, etc. All parts are cut, bored, mortised, etc., to templates, so that the apparently complicated framing goes together rapidly, like a child's puzzle in the hands of an expert. This, together with the systematic handling of material, and the division of labor, expedites the work and keeps the labor cost down to a minimum.

These works have now orders in hand, among others, for 500 box cars, 34 ft. long, for the Chicago, Rock Island & Pacific Ry., and 3,000 box cars, 36 ft. long, for the Baltimore & Ohio R. R. The largest cars ever built here, and perhaps the largest freight cars ever built, are some furniture cars for the Chicago, Rock Island & Pacific Ry. These cars are 50 ft. long and 9 ft. 2 ins. wide, of 60,000 lbs. capacity, and drawings of these we shall give in a later issue.

A GERMAN CLAMP CONNECTION FOR STAGING CONSTRUCTION.

The accompanying sketch shows a clamp connection invented by Mr. Ludwig Gauby, of Oedenburg, Germany, to be used instead of bolted or spiked connections in constructing stagings for building construction of all kinds where the ordinary staging of vertical and horizontal timbers in several stories is used. The method of applying this clamp to the vertical post and the manner in which the horizontal member is inserted through the eye is made clear by this sketch. In Germany the common practice is to use round timbers for staging, and the eye of the clamp is, therefore, made circular, but it is plain that this eye can be made rectangular and of the proper size to fit the square timbers commonly used for staging in America. To all appearances this clamp should be a very useful device wherever staging in large quantities has to be used, as it enables the timber to be used over and over again without damage, is easily removed and shifted to a new point, and allows of almost any desired variation in vertical adjustment, besides being cheap, compact and easily handled by any workman of ordinary intelligence. According to the circular which we have received describing this clamp, it is quite extensively used in Germany, and has given good satisfaction.



A German Clamp Connection for Staging Construction.

Ludwig Gauby, Oedenburg, Germany, Inventor.

WATER SUPPLY FROM THE SAND DUNES OF THE NETHERLANDS.

In commenting upon the water supply of Amsterdam, U. S. Consul G. J. Corey speaks of the sand dunes along the coast as the great source of fresh water. These dunes are formed of sand blown up from the seashore; the basis is sand, but peat is mixed with it in some places, and at the sea-level layers of compressed peat are frequently found; but never on the side nearest the sea. The dunes near Haarlem have a base width of nearly 2½ miles, with summits 20 to 23 ft. above the sea.

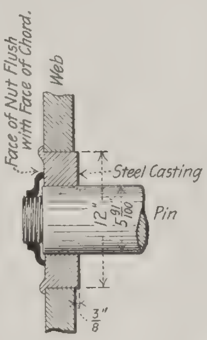
The rainfall percolates through the sand and flows landward and seaward; and the contained water is not only fresh to the sea-level, but to a depth of 66 ft. below sea-level. This would indicate that either the subsoil is based on fresh water, or the hydraulic pressure of the dune water prevents the entrance of sea-water; it is also possible that the water, originally salt, has become freshened by the dune-water pressure.

The quantity of water percolating through the dunes, and contributing to ground-water supply, is estimated at 11.91 ins. per annum. From a range of dunes 2½ miles wide, the quantity of water thus percolating is estimated at 240,000,000 gallons per year per kilometer (.62 mile) of dune length. This quantity can not all be drawn off, however, as a certain volume must be permitted to flow both ways to counteract the pressure of salt water coming from both sides.

For the Amsterdam supply the water is collected in open canals, which are always above the sea level. For the Hague water supply the water is always collected in stoneware pipes, in a bed of shells, 13 ft. below sea-level. In Haarlem the water is collected in wells sunk 50 to 60 ft. below sea-level. This water contains much iron in solution, and it has to be filtered at the three cities named; and when gathered in wells or in pipes it must be aerated before being filtered. The deep drainage system has been in operation for a short time only, and the Haarlem works are still incomplete.

BUSHED PIN CONNECTIONS FOR THE SURPRISE CREEK ARCH, CANADIAN PACIFIC RY.

The novel expedient of bushing the connecting pins was adopted in constructing the 290-ft. 4½-in. steel arch recently constructed over Surprise Creek, on the Canadian Pacific Ry. The main span of this structure consists of two braced steel arch ribs with 6-in. pin connections at the panel points of both top and bottom chords. These pins give sufficient bearing for the posts, diagonals and the top chords, but not sufficient for the heavy pressures of the arched bottom chord. The bearing area of the last members was, therefore, extended by the use of steel disks, or bushings, of the form shown by the accompanying illustration. The general design of this bridge was worked out under the direction of Mr. P. A. Peterson, M. Am. Soc. C. E., Chief Engineer, Canadian Pacific Ry., and the details were developed by the contractors, the Dominion Bridge Co., of Montreal, P. Q.



Bushed Pin Connection for Surprise Creek Steel Arch, Canadian Pacific Ry.

THE RUSSO-CHINESE AGREEMENT, of March 27, 1898, relating to Port Arthur and Ta-lien-wan, is given as follows by the "Peking and Tientsin Times," from what that journal considers a thoroughly reliable source: For the due protection of the Russian Navy the Emperor of China leases to Russia Port Arthur and Ta-lien-wan, together with the adjacent sea; but China reserves her sovereignty over this territory. The limits of the territory transferred are to be fixed in a treaty to be made at St. Petersburg. After such treaty all land within this territory held by Chinese shall be considered as leased by Russia for a period of twenty-five years; though this period may be extended by mutual agreement. One high Russian official shall control all military forces and all civil officers within this region; all Chinese soldiers shall withdraw, but ordinary Chinese inhabitants may remain. It is agreed that Port Arthur shall be a naval port for Russia and China alone, and it will be closed to the warships and merchant marine of all other nations. Part of the harbor of Ta-lien-wan will be a commercial port free to all nations; but another part of this harbor shall be exclusively reserved for Russian and Chinese warships. Russia has the right to build, at these two places, forts, barracks, etc. China agrees that the procedure sanctioned in 1896 regarding the construction of railroads by the board of the Eastern China Railway shall, from the date of the signature of this treaty, be extended so as to include the construction of a branch line to Ta-lien-wan, or, if necessary, in view of the interests involved, of a branch line to the most suitable point on the coast between Newchwang and the Yalu River. Further, the agreement entered into in September, 1896, between the Chinese Government and the Russo-Chinese Bank shall apply with equal strength to this branch line. The direction of this branch line and the places it shall touch shall be arranged between Hsü Ta-jên and the board of the Eastern railroads. The construction of this line shall never, however, be made a ground for encroaching on the sovereignty or integrity of China.

A STEEL HIGHWAY TRACK has been recently invented by Mr. H. L. Stillman, of Charlestown, R. I. For the flat-wearing surface he proposes to use worn-out T-rails with the head sawn off and the base inverted. The stringers are made by sawing diagonally through a block of wood twice as wide as it is high, and then using these two blocks so that the tops are inclined towards the center, and the web of the T-rail is placed between the blocks and secured by a bolt passing through the rail and the two blocks. Flat, or bar iron strips are bolted to the inclined surfaces, and the result is practically a steel trough, with inclined sides and a flat bottom formed by the inverted rail base. The inventor claims that by using these old rails a single track road of this type can be built for less than one-half the cost of an ordinary macadam road of single width.

PUBLICATION OFFICE, ST. PAUL BUILDING, NEW YORK.
CHICAGO OFFICE, 1686 MONADNOCK BLOCK.
BOSTON OFFICE, 299 DEVONSHIRE ST.

SUBSCRIPTION RATES: United States, Canada and Mexico, One Year, $5.00; 6 months, $2.50; 2 months, $1.00. To all other countries in the Postal Union: Regular Edition, One Year, $7.60 (31 shillings); Thin Paper Edition, One Year, $6.31 (26 shillings). SINGLE COPIES of any number in current year, 15 cents.

Mailing addresses may be changed at will by sending both old and new address. The number on the address label of each paper indicates when subscription expires, the last figure indicating the year and the one or two preceding figures the week of that year; for instance, the number 328 means that subscription is paid to the 32d week (that is the issue of Aug. 11) of the year 1898; the change of these figures is the only receipt sent, unless by special request.

ADVERTISING RATES: 20 cents per line. Want notices, special rates, see page 18. Rates for standing advertisements sent on request. Changes in standing advertisements must be received by Monday afternoon; new advertisements, Tuesday afternoon; transient advertisements by Wednesday noon.

It is pleasing to note that, in addition to Naval Constructor Hobson, other staff officers of the United States Navy obtain recognition for their services, in the list of officers recommended for promotion by the Secretary of the Navy. In this list are six Chief Engineers and one Passed Assistant Engineer. While all of these officers of the Steam Engineering staff have well earned their promotion. Chief Engineer Robert W. Millegan, of the battleship "Oregon," especially deserves this recognition, for it is to his unceasing care and attention to the machinery of his ship that the country is indebted for the wonderful run made by this warship, from the Pacific to the Atlantic coast of the United States, and also for the speed developed that insured the surrender of the "Christobal Colon" in the Santiago fight. In the popular admiration for the so-called fighting men of our navy we are too apt to forget the men in the engine-room; yet it is upon the thorough training, technical skill, unending watchfulness and devotion to duty of the steam engineering staff, under conditions that try to the utmost the physical and moral endurance of men, that the captains of our warships practically depend for their victories. A modern battleship would be a useless, floating hulk, without the aid of a multitude of motors that propel and handle the ship, supply ammunition and point the guns and perform many other almost equally important offices. The efficiency of these motors, the manner in which they perform their many offices, is the measure of the efficiency of the warship; and this great responsibility rests upon the shoulders of the engineering staff alone. It must also be remembered that, unlike the officers on the deck, who have the enemy in sight and are nerved to the utmost endeavor by all the excitement of battle, the engineer officers perform their equally important duties shut up in the hold of the vessel and subjected to terrific heat. They cannot personally note the progress of battle; and they only know that in case of torpedo attack or ramming they may be sent to the bottom without ever seeing their destroyer. With a fire-room temperature sometimes exceeding 200° F, the strain upon officers and men is something terrific; and the skill of the first and the unselfish devotion to duty of the latter, as more than once exemplified in the present war, should never be forgotten by the people of the United States.

◆

From a private letter printed in the New York "Sun," from First Assistant Engineer C. N. Offley, U. S. N., in charge of the starboard engine-room of the "Oregon," we gather some hints as to the reasons why this ship made a run of nearly 15,000 miles at an average speed of 11 knots, and yet was in such good condition that she was at once ready for battle on her arrival in Cuban waters. In the first place, the machinery of this ship was well designed, strong in all details; and what was even more essential, it was erected in the ship with the utmost care and thoroughness. But with these qualities given, the strain put upon it in this long voyage was such that would have told upon the best machinery, had it not been kept in constant and thorough repair in all its parts. We find by the letter of Mr. Offley that at every stop in port, connections were overhauled, brasses were examined, cleaned and scraped where necessary, air pumps and circulating pumps were cleaned and repaired, and main cylinders and valve-chests were wiped out and oiled. Equal attention was paid to the boilers, and every leak in pipes, engines, etc., however small, was carefully stopped at once, so that the evaporators and distillers, of 5,000 gallons capacity daily, practically supplied fresh water alone to the boilers. Every endeavor was made to avoid the use of salt water in the boilers; and to the success of this endeavor the record made by the "Oregon" is largely due. In a word, from the day this ship went into commission, the constant effort of her Chief Engineer was to keep all machinery as near perfection as human skill and never-ceasing watchfulness could make it. The whole record of this battleship, taken together, reflects equal honor upon her designers and builders, and upon those who maintained her utmost efficiency under most unusual and trying conditions; conditions never equaled by any other warship of the "Oregon" type.

◆

The complaints of bad water at the various camps of the United States Army raises the question, what is possible in the way of purification where supplies naturally pure are unavailable? The answer depends upon a variety of conditions, the most important of which are the nature of the impurities and the permanency of the camps. Obviously the removal of mud and bacteria are quite different problems, while methods available for permanent camps are quite out of the question for temporary ones. Settling basins or coagulation combined with filtration will remove mud, and sometimes the two processes may be used to supplement each other. Filtration alone, either with or without coagulants, will remove bacteria, if properly conducted. Either distillation or simple boiling are highly effective, but even the latter is very expensive, while the former is so costly as to render it almost impracticable. Where recourse must be had to such extreme measures only water designed for drinking is likely to be treated, and a dual supply, or pure and impure water, in a camp or elsewhere is always dangerous, it being almost impossible to compel even disciplined soldiers to take any extra trouble to secure pure water when there is no physical difference between it and the impure, as is often the case with sewage-polluted as contrasted with unpolluted water. In addition, distilled or boiled water is lacking in oxygen and thus tastes flat, and is unpleasantly warm, unless it is artificially aerated and cooled, which means so much added expense as to render such treatment unlikely. Coming now to filtration, wherever there is a choice between a large central and numerous small, isolated filter plants, the central plant should by all means be chosen as certainly the cheapest and almost invariably the most efficient. That one plant is cheaper than several is too obvious to need explanation; that it is almost sure to be more efficient may not be so self-evident, though none the less true. The reason for this is that the greater the number of filtration plants the less will be the skill of the men in charge. Where camps are not permanent the smaller filter plants may have the advantage of greater ease in transportation, but there may also be more danger of breakage, as the filters or parts of filters are liable to be more fragile as they diminish in size. In general, it may be said of nearly all the portable, so-called domestic filters, beware!!! This by no means applies to all of them, IF they are well cared for. Generally speaking, the freer the filters work, meaning now those of the stone or earthenware type, the less efficient they are. All of them must be cleaned with frequency and care, and sterilized from time to time, the frequency of sterilization depending on the character of the filter. The slow-working porcelain or baked clay filters must operate under pressure, or give extremely low rates of filtration. In conclusion, it may be said that unless it be in the rarest emergencies there is no excuse for typhoid fever in any of our military camps, for at the worst boiled water can almost always be made available as an emergency supply, and the strictest orders issued against drinking any other water, thus throwing the responsibility on the individual soldiers. For a permanent camp it is doubtful whether the government would be justified in shifting the responsibility in this manner, except under the most pressing circumstances, although it is certainly open to question whether severe military punishment should not be given a soldier who endangers his life and that of his companions by carelessly drinking impure water when pure is easily available, especially in view of the severity of the penalties imposed for the infraction of rules which are really less essential to military success.

◆

The slight buckling of some of the members in four of the six stiffening trusses of the Brooklyn Bridge, which was briefly noted in our issue of Aug. 4, calls much needed attention to the necessity of a more rigid regulation of the surface-car traffic over that structure. Among those best informed, it is almost needless to say, there has never been any doubt as to the ability of the bridge to carry the surface cars with absolute safety. It has been equally recognized, however, that if this load was not uniformly distributed, that is, if the trolley cars were to be frequently bunched together over one portion of the suspended structure, while other portions were clear, the strains in certain parts of the structure might assume an undesirable and perhaps an unsafe character. Both of these facts were clearly pointed out by the Board of Experts appointed to investigate the feasibility and practicability of permitting the surface and elevated cars to cross the bridge, in their report of Feb. 8, 1898 (Eng. News, Feb. 18, 1898). After reviewing the different phases of the question carefully, the Board of Experts concluded that the additional load could be carried with perfect safety upon the conditions that:

> The tracks be placed next the outer trusses, and that the minimum clear distance between cars while on the suspended structure shall be 102 ft., and that their speed shall not exceed seven miles per hour.

So important was the strict obedience of this regulation respecting headway considered to be by the Board of Experts, that the remaining four conditions were devised to insure its being enforced beyond doubt, and, finally, the Board advised that at the start the trolley car service should be limited to not more than one-half the number of cars that the railway companies deemed necessary until the employees became sufficiently skilled in the duties they had to perform to ensure that the proper headway would always be preserved.

Notwithstanding the emphasis with which the observance of a perfectly safe interval between cars was insisted upon by the board of expert engineers, and despite their contract agreement to observe it, the surface railways have paid very little attention to the regulation of their traffic in that respect. In fact, as everyone knows who has had occasion to cross the bridge on the surface cars, it has been the exception when the proper headway has been observed. During the hours of heaviest traffic in the morning and evening cars are often run with an interval of barely a car length between them, and on a number of occasions a blockade has packed a part or the whole of the suspended structure with cars only a few feet apart. It was such a blockade which, com-

bined with an unusual expansion of the cables by the very hot weather, threw an excessive compressive strain onto the cantilever portion of the stiffening trusses near the Brooklyn tower and caused the slight buckling of certain of the members. The damage done, while probably immaterial in itself, and certainly of no permanent injury to the supporting power of the bridge as a whole, was sufficient warning that the proper precautions in loading the bridge, which were so strongly recommended, should not be lightly neglected. The disposition of the surface railway companies to neglect these precautions is a perfectly natural one. Their object in crossing the bridge was for the purely business purpose of securing additional traffic and as much of it as possible. From the very beginning the increase has been more than they could accommodate even with great overcrowding during the rush hours, thus encouraging them to disregard any limitation set upon the number of cars which they could run. It is possible that these conditions will be somewhat altered when the elevated railway lines get their full quota of trains in operation across the bridge, and the constant pressure on the surface lines to overcrowd the bridge will be relieved. Whether this is the case or not, there can be no doubt that the bridge officials should see to it that the stipulations respecting the headway between the surface cars are properly observed, which they certainly have not done up to this time.

Municipal ownership of public service industries, in the interests of good government and public welfare, was the keynote of the meeting of the League of American Municipalities, recently held at Detroit. In the discussions of matters bearing upon this question, some important points were brought out which are frequently neglected or overlooked by zealous advocates of this system. These points accentuate the fact that municipal ownership is not necessarily a means of effecting good municipal government or the best relations between capital and labor. One point, which it is hardly within our province to discuss, was that municipal administration should be entirely independent of national or party politics. Another point was that without the civil service system, municipal ownership may be far less advantageous than corporate ownership. If the water or lighting plant is used as a political department, employment in which may be given as a reward for political services rendered to parties or persons, then the plant will almost certainly be operated with less efficiency and less economy than under corporate ownership, as it is at least to the financial interests of a company to keep men who are experienced in the work required of them. If employees are to be appointed, promoted or discharged without regard to merit, then municipal ownership will fail in one of its main purposes, and possibly in all. Still another point was that the class known as the "best citizens" must become something more than fault-finders, and must be prepared to take some active part in municipal affairs if any material improvement is to be made in municipal government. The financial interest of the average citizen in public affairs is small as compared with that of the professional politician, who looks to "politics" as a means of making money, and the latter has therefore a much greater incentive to devote his time to the public business of the municipality, although he does it in his own peculiar way, primarily for his personal benefit. At the present time, municipal administration is left very largely in the hands of men of this latter class. It was pointed out in the discussions referred to that the people of the United States are patriotic enough in time of war, and are willing to risk health, comfort, business, and even life, in the interests of their country. Good municipal government, however, requires patriotism enough in the quiet times of peace to make citizens ready to sacrifice some time and comfort in order that proper attention may be given to municipal affairs by men who work for the best interests of the public and the municipality rather than for merely selfish and personal interests. On the other hand, the idea of sacrifice is carried altogether too far in the demands made on and compensation given salaried officials whose services partake of a professional nature—engineers, city attorneys, health officers and commissioners of public works, where the latter are single-head commissions, with large executive functions. Such men should be sufficiently well paid to attract the best members of the respective classes from which they are drawn, to give dignity to their positions and to place them above the small temptations that lead to the first downward steps in the paths of bribery and corruption. The sacrifices, we urge, should not, as is now so common, be made by these public servants, who are expected to give all or the best part of their time to municipal service. Instead, they should be made (1) by every well-meaning and self-respecting citizen, through keeping himself properly informed regarding the affairs of his municipality and voting accordingly for or against every man and measure submitted to the suffrages of the people; and (2) the sacrifices should be made by the natural leaders of these same good citizens, in giving time to the shaping of public opinion and in serving on boards and commissions more or less honorary in character, it being understood that both routine and expert duties in connection with such commissions will be rendered by properly paid officials, engaged on the civil service plan where practicable.

THE VALUE OF EXTREME FINENESS OF GRINDING FOR HYDRAULIC CEMENT.

The extreme degree of fineness to which hydraulic cements are now required to be ground is a comparatively modern feature of cement specifications. Twenty years ago most cement users laid far greater stress upon the qualities of weight and color, which are now considered insignificant in comparison. When once engineers came to believe in the value of fine grinding, however, the progress made in developing this quality was very rapid. Cements which were regarded as finely ground ten years ago will not meet the standard requirements for fineness today, and the point has apparently not yet been reached where a still greater degree of fineness is not considered as an advantage. As an illustration, a well-known engineer has recently stated that in his opinion the point of fineness at which a cement was "really a cement and ceased to be sand" lay somewhere between a powder which would pass a sieve of 40,000 meshes and one which would pass a sieve of 160,000 meshes per sq. in. Few engineers, perhaps, would hold such an extreme degree of fineness essential, but the tendency everywhere, in Europe as well as in America, is, nevertheless, to place greater stress upon fine grinding and tests for fineness for Portland cement particularly.

It is reasonable to presume that this belief has not gained its popularity with engineers without some basis, and it may repay a little study to determine upon what particular merits for practical use extreme fineness has come to be considered a valuable quality for cement. Such a study will also be of value, we think, in shedding light upon the further problem whether it is desirable to continue the demand for still greater fineness of grinding, particularly such extreme degrees of fineness as those suggested by the figures just quoted.

At the very outset the generally accepted theory as to the inertness of the coarser particles of cement, as it is generally stated, needs to be corrected. By many recent writers on cement it has become the habit to class this coarse residue as practically inert. Some authorities even go so far as to regard it as a mere adulterant or as acting like so much sand. Such statements, when made without qualification, are entirely misleading. Experiments show that this coarse residue has a true cementitious value, of more or less amount, depending upon the size of the particles. Space will be taken here to quote only one of the most recent experiments in proof of this statement, but there are plenty of others which might be quoted with equal force. These figures are compiled from a series of tests made by Mr. David B. Butler, Assoc. M. Inst. C. E., and described by him in a paper published in the last volume of the "Proceedings" of the Institution, and they are as follows:

Portland Cement.

	Retained on —50 sieve.— 6 mos., lbs.	12 mos., lbs.	Passed 50; —ret. on 70— 6 mos., lbs.	12 mos., lbs.	Passed 70; —ret. on 120— 6 mos., lbs.	12 mos., lbs.
A.........	150	160	200	200	250	330
B.........	95	120	110	160	175	200
C.........	90	120	140	170	190	280
D.........	90	140	115	197	192	200
E.........	..	180	190	292	330	420

The experiments show that compared with the fine, impalpable cement dust the coarse particles are evidently of greatly inferior cementitious value, but that they are not wholly inert. In fact, it would perhaps be better if they were, as will be shown further on. The fact obviously is that as the water is able to combine more readily with the fine than with the coarser particles, they set sooner and develop strength faster. Ultimately, the coarse particles also become hydrated and set and harden, but considerably after the fine dust has reached a somewhat permanent stage of hardness. The real objection to the coarse residue, if there is any, lies in this delay in its final hydration rather than in its inertness.

A further investigation of the figures presented by the experiments just quoted brings out this and a number of allied facts of significance. It appears from the accompanying table: (1) That the finer a cement is ground the more rapidly it sets, and, somewhat less certainly, (2) that finer grinding seems to correct any tendency to unsoundness. Both of these conclusions are corroborated by previous French and German experimenters and are not really new, but they illustrate the two facts which it seems needful to emphasize here.

(1)Time of initial set indefinable.
*A specially prepared over-limed cement.

If a finer grinding of cement corrects a tendency to "blow," it is evidently a most important thing for engineers to know. That it does do this seems open to very little doubt, and it may be readily explained, we think, why it should. One of the most prolific causes of "blowing" in cement is quite generally admitted to be an excess of uncombined lime. The hydration of this lime causes expansion whether a cement is fine or coarse, but in the finely ground powder the hydration takes place during gaging, owing to the ease with which the water gets access to the almost impalpable grains, and the expansion is immediate and uniform and does no damage. In the coarse powder, on the contrary, the uncombined lime in the interior of the particles does not hydrate, and consequently expand until the surrounding finer grains have set and thus swelling and cracking results; or, in other words, the cement "blows."

That the foregoing explanation covers all the causes of unsoundness in cements no one will contend for a moment, but it does give a reason, we think, why a very finely ground cement shows less tendency to "blow" than the same cement coarsely ground. It indicates, furthermore, that in holding the theory that the coarser residue is inert we neglect a possible source of danger. If the coarse particles were really inert, like so much sand, for instance, they would not be acted upon at all by water. All the effect they could possibly have would be to make the hardened cement more porous and thus allow the freer entrance of disruptive elements into the cement stone. The great importance of this feature of porosity was fully discussed in Engineering News of July 29, 1897, and need not be alluded to further here.

The evidence deduced so far, while it is not so conclusive as one could wish, tends on the whole to show that it is not the inertness, but the activity of the coarse residue, that makes it most undesirable. If inertness were the only charge against the coarse residue, the moderate percentage of coarse material would be of no great importance. About the only disadvantage resulting would be a reduction in the ability of the cement to take sand. The hardening of a finer cement mixed neat is more rapid, but it attains less final strength than when more coarsely ground.

The effect of fine grinding upon the setting properties of cement is also an important matter to be kept in mind. The tendency of engineers to-day seems to be to call for slower setting cements as well as finer grinding. The figures given in the table and corroborated by other experiments indicate pretty certainly that these qualities are antagonistic to each other, and if engineers persist in demanding both something must be done by the manufacturer to modify this antagonism. The question is, what will it be? Aeration will usually render the cement slower setting, but this is a process which takes time and labor to accomplish properly, and in the rush of manufacture and construction work it is likely to be neglected for some easier method. The danger is that adulterants may be employed.

By adding a small percentage of ground gypsum to the cement the figures given in the table show that the rate of setting is materially retarded. They also show that the tendency to blow is increased. This form of adulteration is mentioned particularly because it is already largely practiced in Germany. In fact, the addition of not over 2 per cent. of powdered gypsum to Portland cement is sanctioned by the German Cement Manufacturers' Association. Several high authorities maintain, however, that the addition of gypsum should never be sanctioned where cement is to be used in sea water, and experiments recently made show that the addition of 5 per cent. of gypsum causes decided disintegration. Even if the addition of 2 per cent. of gypsum is allowable, it is evidently very easy to overstep the mark. Until, then, the ultimate effect of adding gypsum to retard the rate of setting is more fully investigated it seems the part of wisdom to regard it with suspicion.

The next feature of extreme fineness of grinding which is of most particular interest to engineers is its effect upon the strength of cement. Fortunately, the evidence is so complete upon this point that it can be quickly dismissed. Gaged neat, as already stated, a very fine cement is stronger at early ages and weaker at great ages than a cement more coarsely ground. Mixed into mortar with sand, however, the superior strength of a fine cement over a coarser cement is very evident, at least in the earlier periods of hardening. A mortar high in sand exhibits this value of fine grinding more, however, than a mortar low in sand. In many cases a very rich mortar made with a coarse cement reaches nearly the same ultimate strength as when made with a very fine cement. The attainment of extreme fineness may not always, therefore, be economical when the extra cost of fine grinding is considered. This bears directly upon the inquiry already suggested, whether such extreme fineness as powder which will all pass a 40,000 mesh sieve is practically worth attaining.

There is much to be said upon this question and space can be taken here only to suggest a few of the most prominent considerations. It seems likely first of all that to produce regularly a cement finer than will pass a 40,000 mesh sieve means considerably increased cost in manufacture. As a single illustration, manufacturers question whether mechanical screening is practicable where screens finer than 200 meshes per lineal inch are required, and if finer grinding is required some new method of separating the sufficiently fine from the coarse powder must be devised. Doubtless, such a method can be devised, but can it be done without increasing the cost? This is a fact not yet determined. The further problem of too rapid setting because of such very fine grinding is also yet to be solved. When, however, these questions are finally settled there is still another to be decided. May it not be cheaper to develop a certain strength of mortar by using a coarse cement low in sand than by using a fine cement high in sand? We know for a fact that this is true of many similar cases. It is cheaper, for instance, to attain a certain strength of mortar or concrete in some cases by using a rich natural cement mixture than it is by using a poor Portland cement mixture. The case of using a fine or a coarse cement is quite similar.

To summarize what has been said we may conclude: (1) The coarser particles of cement are not inert but have a certain cementitious value approximately in inverse ratio to their size, and because of this activity introduce an element of danger from blowing; (2) the extreme fine grinding of cement decreases its cohesive strength, but immensely increases its adhesive strength, and, consequently, its value as cement, but the attainment of extreme fineness may not always be economical in practical construction, owing to the extra cost of fine grinding; (3) the finer grinding of cement greatly hastens its value of setting and may introduce the necessity of using adulterants or other artificial means of retardation; (4) finer grinding seems to correct a tendency to unsoundness by allowing the water to attack the uncombined lime during gaging instead of after setting, as is the case when it is confined within the coarse particles.

On the whole, these conclusions demonstrate the advantage of fine grinding. They bring out clearly, however, that this merit is not entirely unalloyed with disadvantages. This is the truth which we have wished especially to emphasize in this brief discussion, for the reason that in many instances it has seemed to us that the greatly superior strengths shown by fine cements over coarse cements in short-time neat cement tests has led cement users to grant them superiority on that evidence alone. As we pointed out in our issue of July 28, high short-time tests are likely to be overestimated in practical value if good judgment is not exercised. Fineness of grinding considered from the point of view of strength alone involves a similar danger.

In conclusion, attention may be directed to the figures in the accompanying table, which show the relation between the rise in temperature of cement during setting and its soundness. Some authorities, as is well known, have advocated this rise in temperature as a test for soundness. The figures in the table do not support this theory. In fact, they show that this evolution of heat bears a distinct relation to the time occupied in setting. To require that a cement shall show little or no rise in temperature during setting ensures an extremely slow setting cement but does not guard against an unsound one.

◆

LETTERS TO THE EDITOR.

Report on the Condition of the Paints on the 155th St. Viaduct, New York City.

Sir: We have read in Engineering News of July 28, Mr. Henry B. Seaman's comment on your editorial of July 21, in which, referring to the paints used on the 155th St. Viaduct, he says: "All the paints used in this test were patented paints." We wish to take exception to this statement, as Dixon's Silica-Graphite Paint was one of the paints used, and it is neither patented nor a compound. The name silica-graphite fully designates what the pigment is, namely, silica and graphite. The silica is not silicate of alumina, as some have wrongly supposed, but is, practically speaking, a pure silica ground to an impalpable degree of fineness. The graphite is not one of the amorphous forms of graphite, nor is it of the soft Ceylon variety; it is a hard, tough, flake graphite which comes from the famous Ticonderoga mines in New York state, which are owned by the Dixon company. Graphite paints, to possess the greatest durabliity, so far as the pigment is concerned, must be made of the toughest and best form of graphite, and graphite varies greatly.

Yours very truly,
Jos. Dixon Crucible Co.

Jersey City, N. J., Aug. 10, 1898.

The "Arithmetic of the Steam Engine" Again.

Sir: Waiving all further discussion of those points relating to sensible heat, horse-power, etc., about which we appear to differ, I would beg a few more lines of space to defend the position regarding energy, momentum and vis viva which I have taken in the little volume that has given rise to this correspondence.

To begin at the beginning, everything connected with these subjects starts from the well-known relation which, derived from actual experiment, governs the movements of heavy bodies acted upon by a constant accelerating force, namely:

$$v = a\,t. \qquad (1)$$

In which relation v = velocity in feet per second at a given instant; t = corresponding time of action in seconds, and a = acceleration due to constant force in feet per second, per second. From (1) we derive:

$$t = \frac{v}{a}$$

Multiplying both sides of the equation by $\frac{v}{2}$

$$\frac{t\,v}{2} = \frac{v^2}{2\,a}$$

Now $\frac{v}{2}$ = mean velocity of a body moving from rest under the influence of the acceleration, a, at the instant when its velocity = v. But time into mean velocity = distance covered during the given time, hence the next above equation becomes:

$$h = \frac{v^2}{2\,a}, \qquad (2)$$

In which equation h = distance traveled in given time t. The element of time disappears from this equation.

The acceleration due to terrestrial gravitation being represented by g, (1) and (2) become for the special case of heavy bodies falling upon the surface of the earth:

$$v = g\,t. \qquad (3)$$

$$h = \frac{v^2}{2\,g}. \qquad (4)$$

According to the second clause of Newton's second law of motion, as quoted by Jamieson, "The change in the quantity of motion is therefore proportional to the force applied, and takes place in the direction of that force." Hence, the corollary of primary significance in dyramics—"Constant or uniform forces acting freely upon heavy bodies impart to such bodies accelerations proportiona to the intensities of the forces themselves." (Arithmetic of the Steam Engine. p. 61.) This law enables us to measure the intensity of forces imparting given accelerations to bodies possessing certain weights, by comparing these accelerations to the acceleration imparted by gravity. The law may be thus stated: A force, F, imparting an acceleration (or retardation), a, to a body of weight, W, is to such weight as a is to g. Or, expressed as an equation:

$$\frac{F}{W} = \frac{a}{g}. \qquad (5)$$

Which reads: Force is to weight as acceleration is to 32.2.

These elementary preliminaries being established, let us revert to our formulae (1) to (5). From (1), we have:

$$a = \frac{v}{t}$$

Substituting this value of a in (5) gives:

$$F\,t = \frac{W\,v}{g}. \qquad (6)$$

This is the formula of momentum, and it gives the steady force, F, necessary to communicate or extinguish the stored energy of a body of weight, W, moving with a velocity, v, in the time, t, which elapses before the body comes to a state of rest.

Multiplying both sides of (6) by $\frac{V}{2}$, gives:

$$\frac{F\,t\,v}{2} = \frac{W\,V^2}{2\,g}$$

But we have already seen that $\frac{t\,v}{2} = h$. Therefore,

$$F\,h = \frac{W\,V^2}{2\,g}. \qquad (7)$$

This is the formula for vis viva, and it gives the steady force, F, necessary to communicate or extinguish the stored energy of a body of weight, W, moving with a velocity, v, in the distance, h, traversed by the body before coming to a state of rest.

Every heavy body moving with a certain velocity has stored within it, in virtue of its property of inertia, a certain amount of energy depending upon its weight and velocity. We estimate this energy by the force necessary to produce or destroy it. The right hand member of (6) represents the passive force, F, necessary to destroy the energy stored in a body of weight, W, moving with the velocity, v, in one second of time. The left hand member is the product of the force and any given time necessary to accomplish the same result. Note, as bearing upon your previous criticism, that the left hand member is simply "weight into time." The necessary element of motion is only to be found in the right hand member.

The right hand member of (7) represents the passive force, F, necessary to destroy the stored energy in the distance of one foot, assuming throughout English units. The left hand member is the product of the force and any given distance necessary to accomplish the same result. Note again that the left hand member of (7) is "weight into distance."

An illustration: A flywheel rotating with a certain velocity contains a certain amount of energy stored in its rim. If steam be suddenly shut off and a steady, stationary force of a certain number of pounds be applied to the brake-drum, the stored energy will be gradually extinguished and the wheel will stop in a certain number of seconds. During that time it will perform a certain number of revolutions before coming to a stop. The energy stored in the wheel is the same, and the force applied to the break is the same, and we can estimate the amount of energy neutralized by the given force, neglecting other resistances, either in terms of time, when it becomes a problem in momentum, or in terms of distance, when it becomes one of vis viva. This is why I said in my book that "Momentum represents the stored or acquired energy of weight acting through time," and that "Vis viva represents the stored or acquired energy of weight acting through distance."

No exposition of mathematical principles is complete without a numerical example. Let us add a little to the data of your example of a ship weighing 10,000 tons, acted upon by a weight of 1 lb. for a period of 100 seconds, so as to make it amenable to calculation, and let us suppose that the ship has been moving with a certain steady velocity, V, when the propelling force is suddenly withdrawn and she forges ahead in virtue of her inertia, until stopped by the steady resistance of 1 lb. applied for a period of 100 seconds. With what velocity was she moving, and in what distance did she stop? Reducing the tons to pounds and applying (6) we have:

$$V = \frac{1 \times 100 \times 32.2}{20000000} = 0.000161 \text{ ft. per second.}$$

As for the distance traveled before stopping, we have above her initial velocity, which was gradually reduced to zero. Her mean velocity was therefore one-half of the above, or 0,0000805 feet per second, and it was maintained for 100 seconds. Hence the required distance is 0,00805 feet. This result can also be obtained directly by using (7). This example is, of course, fanciful, but it serves the purpose of illustration.

It will be noted that in all the above illustrations the stored energy only has been considered. In the case of a locomotive running with a certain regular speed the resistances offered only prevent an increase of velocity. If the steam be shut off, they overcome the stored energy and bring the machine to a stop. When speed is maintained against resistance, the problem is one of work and neither of momentum nor vis viva.

I could not explain all this so fully in my little book without sacrifice of brevity. I believe, however, that the subject is of sufficient importance to render the above elucidation of interest and possibly of utility to many of your readers.

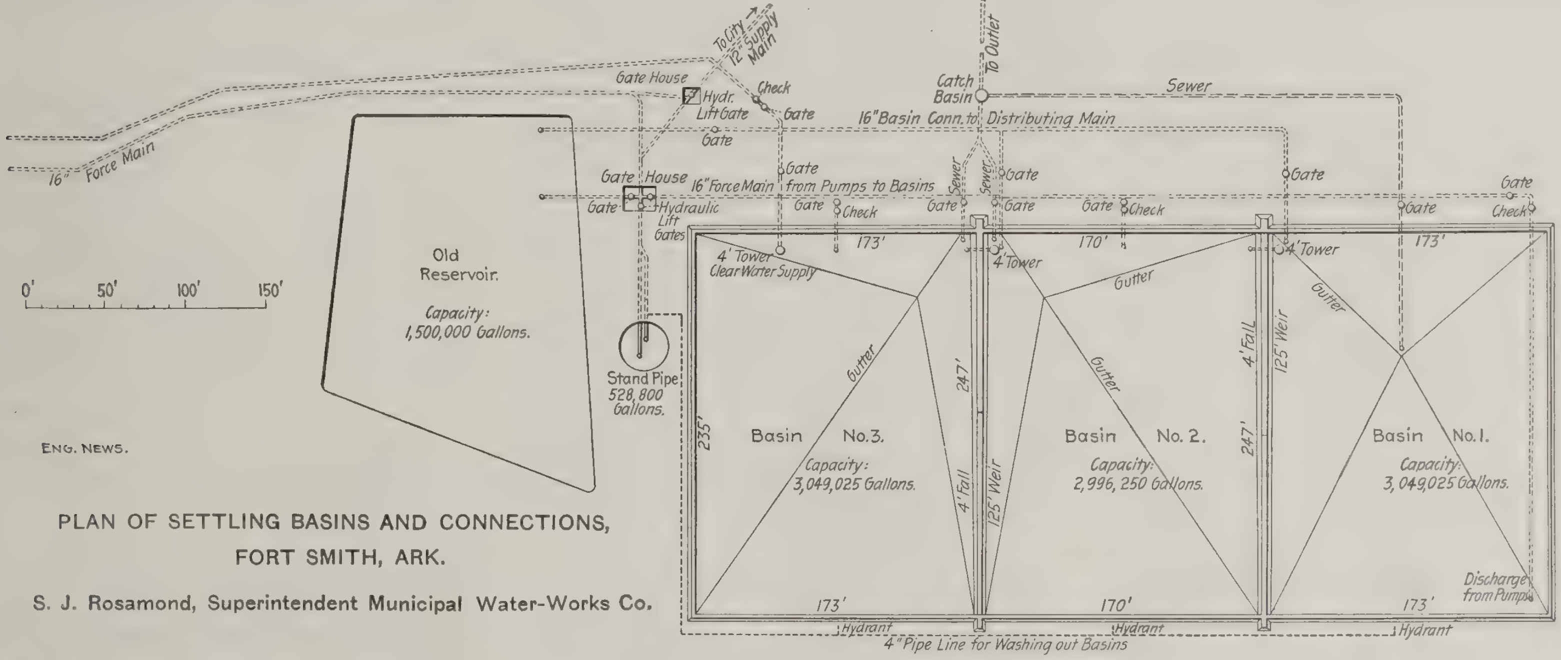
Very faithfully yours,
E. Sherman Gould.

Yonkers, N. Y., Aug. 1, 1898.

(We give place to Mr. Gould's letter, and will say that our difference with him relates practically only to the definition of the terms energy, momentum and vis viva. The last-named term we consider and obsolete one.—Ed.)

THE NEW SETTLING AND AERATING BASINS, FORT SMITH, ARK.

Three new settling basins, with a combined capacity of about 9,000,000 gallons, were put in operation at Fort Smith, Ark., in November, 1897. They were designed by Mr. S. J. Rosamond, Superintendent of the Municipal Water-Works Co., and built under his direction. We are indebted to Mr. Rosamond for the information from which our description of the basins has been prepared.



PLAN OF SETTLING BASINS AND CONNECTIONS, FORT SMITH, ARK.

S. J. Rosamond, Superintendent Municipal Water-Works Co.

Fort Smith had a population of 11,311 by the U. S. Census of 1890, and of 20,100 by the directory census of 1898. The water-works were built in 1884. The supply is pumped from the Poteau River, to a stand-pipe and direct and also to settling basins. Besides the settling basins there is an old reservoir with a capacity of 1,500,000 gallons.

The old and new basins, the stand-pipe and connections are shown in plan by the accompanying illustration. The pumping station is about 2,500 ft. from the old basin.

The bottom of the new basins is solid rock, covered with 2 ins. of cement mortar. The basins are so located on sloping ground as to give a fall of 4 ft. from No. 1 into No. 2, and from the latter into No. 3. Advantage is taken of this to aerate the water by passing it over weirs, now stopped off to a length of 75 ft., but with a full length of 125 ft. for use when the consumption increases. Clear water may be drawn from any one of the three basins through a tower 4 ft. in diameter, and 15, 14 and 10 ft. in height for basins Nos. 1, 2 and 3, respectively. These towers are of ¼-in. wrought iron, and are provided with inlets at different levels so the water may be drawn from the top, middle or bottom of the basin, if desired; generally it will be drawn from the top.

The average water consumption is about 2,000,000 gallons a day in summer. The Poteau River, from which the supply is taken, is quite turbid at times. The settling basins, Mr. Rosamond states, have given satisfactory results. He also says that the stand-pipe is filled only when the river is clear, and is always drawn upon for fires, the direct pressure being reserved for emergencies. In case of an exceptional demand it might be necessary to use water without sedimentation, but probably this occurs only at long intervals.

GUN-FIRE ANALYSIS OF THE SANTIAGO SEA-FIGHT.

The gun-fire is analyzed, for the Santiago sea-fight of July 3, by Lieut. B. W. Wells, Flag Secretary for Commodore Schley. The total number of guns on the seven American and six Spanish ships engaged is given in detail as follows:

United States.		Spanish.	
Caliber.	No. guns.	Caliber.	No. guns.
13-in. B. L.	8	11-in. B. L.	6
12-in. B. L.	6	6-in. R. F.	10
8-in. B. L.	32	5.5-in. R. F.	30
6-in. B. L.	14	4.7-in. R. F.	6
5-in. R. F.	12	12-pdrs.	4
4-in. R. F.	6	6-pdrs.	38
6-pdrs.	90	1-pdrs.	10
1-pdrs.	28	Maxim-Nordenfeldt	4
Maxim-Nordenfeldt	3	Hontoria 37-mm.	24
Machine guns	26	Machine guns	14
Total	225	Total	146

While the United States had fourteen 13-in. and 12-in. guns, only two shots from these struck the enemy's ships. In rapid-fire guns the Spanish had 50 of this type, including 12-pdrs., against 18 on the American ships; in smaller guns the proportions were 131 on the U. S. ships to 76 on the Spanish ships, omitting machine guns. The accurately destructive fire of these small guns on the American ships drove the Spanish from their guns; though the 8-in. American fire probably did the most serious damage.

When the Spanish ships left the harbor they headed westward and brought their full port batteries to bear; while the American ships were closing in bows-on. As a result, the following table gives a fair estimate of the number of guns engaged on each side:

United States.		Spanish.	
Caliber.	No. guns.	Caliber.	No. guns.
13-in.	4	11-in.	6
12-in.	4	6-in. R. F.	5
8-in.	32	5.5-in. R. F.	15
6-in.	7	4.7-in. R. F.	3
5-in. R. F.	6	12-pdrs.	4
4-in. R. F.	3	6-pdrs.	21
6-pdrs.	47	1-pdrs.	5
3-pdrs.	4	Hontoria 37-mm.	21
1-pdrs.	4	Maxim-Nordenfeldt	4
Machine guns	8	Machine guns	7
Total	119	Total	91

To determine the metal thrown per minute, says Lieut. Wells, take the time allowed from fire to fire for the 13-in. gun as a unit. Then in that length of time the weight of metal from the 13-in. guns would be 4,400 lbs. The allowed time from fire to fire for the 13-in. is 320 seconds, and for the 12-in. it is 300 seconds, hence the weight of metal thrown by the 12-in. in 320 seconds is 3,613 lbs. These quantities for other calibers are found similarly; hence we have:

Guns.	Metal, lbs.	Guns.	Metal, lbs.
13-in.	4,400	4-in. R. F.	1,584
12-in.	3,613	6-pdrs.	7,520
8-in.	12,000	3-pdrs.	384
6-in.	1,778	1-pdrs.	1,720
5-in. R. F.	3,840		

Total weight thrown in 320 seconds, lbs. 35,839
Weight thrown per minute, lbs. 6,720

In determining this quantity for the Spanish guns the same time allowances are used as for similar types of United States guns. The weights of projectiles are for common shell, and have been ascertained as nearly as possible. The time unit is 300 seconds, being the interval from fire to fire of the United States 12-in. gun.

Guns.	Metal, lbs.	Guns.	Metal, lbs.
11-in.	3,516	4.7-in. R. F.	1,584
6-in.	3,750	6-pdrs.	3,150
5.5-in. R. F.	10,277	1-pdrs.	960
12-pdrs.	800	Maxim-Nordenfeldt ...	300

Total weight thrown in 300 seconds, lbs. 24,133
Weight thrown per minute, lbs. 4,827
Machine guns are omitted.

It will be noted that the weights thrown per minute were as 6,720 to 4,827; this is approximately as 139 to 100. Therefore the fire of the United States ships, instead of being treble that of the Spanish ships, was one-third greater, and this small difference could not alone account for the disparity in results.

Lieut. Wells concludes that the victory was due, in part, to the following causes:

1. The greater accuracy of fire of the United States vessels.

2. The use of wood in the Spanish ships to such an extent as to render the extinguishing of a fire practically impossible after several large shells had cut up water mains and hose.

3. The greater number of guns of 8-in. caliber on the United States ships.

4. The better morale due to the fact that all the crews had been under fire a number of times during bombardments along the Cuban coast at Santiago de Cuba and at San Juan.

5. The value of a large secondary battery was demonstrated, for the work of the 6-pdrs. contributed largely in keeping down the enemy's fire by driving them from their guns.

6. The necessity for more and better protection for the gun's crews. With the men disabled or driven from their stations, the ship is of little value as a fighting machine. The armor of the "Colon" kept out 5-in. shells at a range of about 3,000 yds. This would be a very great superiority in many cases.

7. The small danger of injury to the water-line portions of the ships. So far as is known, no vessel was penetrated between wind and water. Moderate armor protection at the water-line, with a strong protective deck, would permit a more efficient distribution of the armor around the gun positions.

◆

A HIGHER INDUSTRIAL AND COMMERCIAL EDUCATION.*

The material prosperity of any country is the foundation of the happiness and of the progressive enlightment of its people. To learn the essential conditions of such a prosperity, therefore, is a matter of supreme importance. In the former times, all knowledge of material things was traditional, and had to be learned by the traditional methods; to-day nearly all knowledge is scientific, and should be acquired by scientific methods. Formerly the industries were directed by mechanics, who by a long apprenticeship had slowly acquired the manual methods of their predecessors; to-day they are most successfully guided by men of large scientific attainments; and in the near future such scientific direction will be absolutely essential wherever there is free competition in the market to be supplied. Prosperity, or even supremacy, in material things in the past, is, therefore, no promise of such a position in the future, and as a proof of this, we have but to compare the past achievements of England and its present subordination to Germany.

That an interior country like Germany, without a navy, and with little foreign commerce, could in a quarter of a century increase her manufacturing capacity ten-fold and make it equal to that of England;* increase her shipping twenty-fold, making it second to that of England; effectually establish a regular export trade with every country on the globe, and by at once cheapening products and improving their quality, put herself in a position to hold these markets indefinitely; that all this could be accomplished in the face of open competition, and in this age of universal publicity, is indeed marvelous and would alone prove that old methods have lost their potency, and that something new has arisen under the sun.

When we seek an explanation of these wonderful achievements we find only a rational and provident application of means to ends, but on the most gigantic scale and persevered in far more consistently than has ever before been even planned, to say nothing of the execution. It is evident that the efficient direction of any industry to-day demands a very large amount of technical knowledge which cannot be learned at the bench or in the shops. While self-education is always possible, the obstacles are commonly prohibitive, and at best the results are meagre and unsatisfactory. Germany has seen this situation most clearly, and it is to her clear conception of this problem, and her rational and thorough solution of it, that has raised her industrially from poverty and obscurity to wealth and fame in the short period of a quarter of a century.

The German Mono-technic Schools.

Seeing that the capacity for production is limited only by the inteligence and foresight of a people, and that there is a rapidly growing and prospectively unlimited demand for all kinds of artistically manufactured goods, Germany set to work some twenty-five years ago to supply this demand by the intelligently directed labors of her own people. This country had long been the home of classical and military learning, but it now became also the very center and head of technical and industrial education. The members of this society are all quite familiar with her high-grade engineering schools, but we are not so familiar with her industrial schools. In fact, we have commonly spoken of these with more or less indifference, calling them trade-schools. We have assumed that the difference between them and the engineering schools was one of kind, rather than of quality or degree. As a result of some recent study of the leading industrial schools in Germany, I am inclined to question the justice of our position. Since the sciences of mathematics, of physics, of electricity, of chemistry, of mechanics, of steam engineering, and of the materials employed, enter so largely into all these school courses, they are, in fact, schools of applied science, and they now pass in Germany under the very appropriate name of mono-technic schools. Such schools are there found for all the leading industries of the empire, and there are many schools for the same industry. Thus there are in Germany 13 schools devoted to the textile industries, each with its peculiar organization specially adapted to the region in which it is placed. As little duplication as posible is practiced, and when the same field is covered in two or more schools, variations in methods are introduced for the purpose of comparing results. The students entering these schools have first to complete the course of study in the "Real Schools" (or say, through the sophomore year of our engineering schools), and then the course of study in the mono-technic schools is three years of 45 hours a week, on the successful completion of which certificates are granted.

The fine and costly buildings in which these schools are installed; their elaborate equipment with all the needful chemical and physical laboratories, and machinery to convert them into regular commercial factories; their large corps of trained teachers, and the very small number of students admitted to take their full courses; the administrative care and oversight given to them, and their very small tuition fees, all serve to make the training given in them extraordianrily expensive to the state. Thus the textile schools of Crefield had last year only 108 regular day students in the weaving school, and 40 in the dyeing and finishing school. In the weaving school was the director with 15 assistant lecturers, and six other assistants; in the dyeing and finishing school there were the director and three assistant lecturers, a special chemist for dyeing and for finishing, or a force of 29 instructors for 146 regular students. There were, however, irregular students in attendance on night and Sunday courses. The plant of this school included extended chemical and physical laboratories fully equipped, drawing rooms, lecture and testing rooms, chemical museum, library and reading rooms. The mechanical equipment was that of a complete weaving, dyeing and finishing works, for all the finer grades of woolen and silk goods. Commercial work is done on a large scale, the students doing the work under the direction of the assistants. Specially difficult tasks in dyeing are here undertaken and successfully accomplished, and regular consignments of this character are made by some of the leading factories of the empire.

This school is only one of hundreds in Germany which are training up a class of men for the direction of all kinds of commercial works in which scientific knowledge is finding its embodiment and application. As a result of this training we find such great industries as the Aniline and Soda works at Ludwigshafen on the Rhine, which has grown from employing a total force in 1865 of 30 people to employing 5,000 men and over a hundred trained chemists in 1897. Also the optical and electrical works of Schuckert & Co., at Nuremberg, which started on a very small scale in 1882, but which now employs over 4,000 men, besides a large scientific staff, and which had in 1897 unexecuted orders on hand aggregating $15,000,000. Three-fourths of of all the coloring matters and pharmaceutical products now produced from coal tar is made in Germany, their total annual products of this class aggregating $40,000,000. The earliest chemical discoveries of these products were made in England, but there was not sufficient knowledge of applied chemistry in that country to utilize these discoveries.* It is such examples as these, of which there are many, that indicate that Germany is reaping the fruits of the painstaking and farseeing policy she has entered upon, and if other nations wish to share her prosperity, they must act with a like wisdom and determination. The proof that Germany's remarkable industrial prosperity is traceable very largely to her educational methods† is so patent to the people themselves that they voluntarily unite to support schools in their particular trades. Thus of the 248 mono-technic schools in Prussia alone, which are so supported, the painters and decorators have 32; the shoemakers, 9; the tailors, 16; the bakers, 20; the butchers, 6; the smiths, 26, and so on.

Every trade has its own school aside from those supported by the state and by the municipalities. The artisans themselves see that systematic and scientific teaching entirely outclasses the old apprenticeship system, and these schools are constantly multiplying. In Saxony alone, there are 111 of these mono-technic schools, besides ten schools of agriculture and 40 of commerce. In the Grand Duchy of Hesse, with a million inhabitants, there are schools of agriculture and sculpture, nine schools for artisans, 43 for industries, and 82 schools of design. The Grand Duchy of Baden, with 1,600,000 inhabitants, supports schools of industry, architecture, commerce, clock-making, cabinet-work and music, with an annual expenditure of $280,000. In addition to these schools peripatetic teachers are employed to go from house to house to instruct in embroidery and the use of the sewing machine, the state selling these machines at a greatly reduced cost on condition that the purchaser shall explain its workings to her neighbors. In fact, Germany, as viewed from without, would seem to be in the throes of a kind of educational fever. No doubt a large part of this educational work has been necessary as a result of the very backward condition of the common people along these lines, and to such an extent these methods could not find a place in this country, but aside and beyond these limits may we not see in the example of Germany the royal road to industrial prosperity? While the industrious character of the people, the military spirit which pervades all her industrial and commercial affairs as well as the military department; the absolute stability of her governmental policy and the fixedness of her currency and financial basis; and the disposition to be satisfied with small wages and profits so long as these both rest on a sure and permanent footing; while all these certainly contribute largely to her present material prosperity, these same advantages are also held with her in common by some other countries which are not, however, sharing her present prosperity. The tremendous military budget of Germany cuts deeply into her productive profits, so that without this her commercial advancement would have been still more marked. It is not her army of soldiers, however, which other nations need to fear, but her army of scientifically trained directors of industrial enterprises, and of the highly educated commercial agents, at which they may well tremble.

But Germany not only educates the men who manufacture, but she is also beginning to look well to the training of the men who are to carry their goods to the ends of the earth and report back the peculiar needs of every locality. Schools of commerce are being organized, modeled after those of France and Belgium, in which in addition to what is taught in our "commercial colleges," will be found a speaking and writing acquaintance with several foreign languages, especially English, Spanish and French, if these have not already been acquired; political economy; industrial and patent laws; railroading; shipping; postal and telegraph regulations; banking, exchange, coinage and national schemes of finance; industrial history; commercial geography, etc. A German National conference was held on this subject a year ago, and a new system of commercial education is now being established all over the empire. Modern languages form a part of the elementary school training, especially English, so that the entering students in these schools are likely to be well equipped in this particular. With such material as these schools will turn out, their students coming from the better mercantile classes, and having the manners and bearings of gentlemen, the large manufacturing and mercantile houses can establish branches in all the leading foreign countries, and with the system of foreign German banks, which are even now found everywhere, the conditions are ripe for the ready and rapid sale of German products in all parts of the world. From a remarkable publication by Mr. Frederick Emory, just issued from the Bureau of Foreign Commerce of our State Department, on the recent increase in our foreign trade, and in reference to the necessity for the individual manufacturer and merchant to study carefully the trade conditions in foreign countries, I quote:

> Nor is it with the relation of the different nations to one another that we are alone concerned. The industrial changes current within the territory of each obtain a new and much graver importance in their possible effect upon our nascent development as an exporter of manufactured goods. The conditions contributing to the rapid growth of manufacturers in recent years; the fiscal changes in Russia, India and Japan as well as in some of the Latin-

*Report of Technical Instruction Committee, City of Manchester, England, 1897, page 12.

†This is universally acknowledged by all who have examined into her system. See English Consular Report, No. 2,046, entitled, "Trade in Germany," April, 1898.

American countries; the extraordinary impulse given to the industrial growth of the German Empire as a factor of international trade; the advance of Russia on similar lines; the rapid progress of the Siberian Railroads toward an open port on the Yellow Sea; the efforts of Great Britain to meet the encroachments of other nations; the decline of the sugar industry in the West Indies as a result of the beet-sugar competition; the troubles of Spain with her colonies; the discovery of gold in Alaska and the adjacent territories in British Columbia; the tariff legislation of the United States, Canada and other countries; all the phases of economic changes during the past year, have an interest and importance for the individual operative in the United States which are greatly enhanced by the transformation now going on in our industrial life, converting us slowly but surely from a people absorbed with the internal development of a virgin continent into one of the great commercial powers of the world, with the international interests and responsibilities which such a position naturally **applies.**

Evidently in order to keep abreast of all such changes which are constantly going on the world over, a special class of highly trained men are required. And here too, the supply of such a new and improved kind of clerical assistance would at once create its own demand.

It would seem the time is now ripe in this country for the establishment of such schools. They are needed as much or more for the training of our foreign consuls as for the commercial agents of the large business houses and industrial establishments.* In France there are eleven of these high-grade colleges of commerce.†

The course of study in these colleges of commerce is two years, with a preparatory year, all of 33 lecture hours a week. The following is a brief outline of the distribution of this time, the minimum age being 16 years, which is predicated upon about our college entrance conditions, to which has been added in the preparatory year about all that is taught in our American so-called commercial colleges:

Distribution of Time in the French Colleges of Commerce.
(Time two years.)

11 hours per week to Commercial Methods and Transactions in what is called the commercial bureau.
3 hours of Commercial Geography.
1 hour of the History of Commerce.
2 hours to a study of Commercial Products, involving the actual handling of the materials.
2 hours to Commercial Law, maritime and industrial.
1 hour to Political Economy.
1 hour to Typewriting.
4 hours to a speaking and writing knowledge of English.
4 hours to a speaking and writing knowledge of some other modern language, as German, Spanish, Italian or Arabic.
3 hours to some special course in Transportation, Chemistry, Microscopy, Commercial Technology or Stenography.

The Lesson for Americans to Learn.

But, you may say, what is all this to us? Have we not the finest system of public schools in the world? Have we not any number of manual training schools and numerous Pratt and Armour Institutions? And finally, have we not a great many engineering schools as good as the best, even in Germany? And have we not "Commercial Colleges" without number? Suppose I grant all this, may I not still say that the common schools give no special preparation for any kind of employment; that the manual training schools likewise fit for nothing in particular; that our engineering schools fit for very narrow lines of professional employment and commonly educate men away from the industrial pursuits rather than towards them; and as for our so-called commercial colleges what do they teach beyond arithmetic, book-keeping, stenography and typewriting? Where then does the scientific training for the manufacturing and commercial industries come in? I submit that it does not come in at all. That our factories and business houses are largely managed by men of little or no scientific training, who have learned their craft in the traditional way, who are, however, of an inventive turn of mind and who read the trade journals. They are a great credit to the system that has produced them, and many of them have become self-educated into an excellent state of efficiency; but they are far from the ideal directors of such business and very far indeed from the standard already achieved in Germany.

The most essential conditions of our future material prosperity, therefore, are, as I conceive them, a specific scientific training for the directors of each and every kind of manufacturing and commercial activity. This is the burden of my address; the imperial and paternal government of Germany has worked out this problem to a most fruitful issue, but probably no other country could duplicate it. England has been trying for ten years to do so, but with very poor success; instead of highly educating a few leaders and directors of industry and commerce, they are vainly trying to raise the whole class of apprentices and clerks by a wholesale system of shallow night-school instruction. Surely a duplication of the imperial German system is not to be thought of in this union of 45 independent States. The great question for us to solve is how to obtain a corresponding specific training for our industrial officials. The problem is a difficult one; to expect that our American municipalities would engage in such a rational expenditure of funds is beyond our credulity or hope. Our State Legislatures could hardly be expected to realize this need so fully as to inaugurate and consistently to support a series of such schools. The National Government now pays out directly to the several State agricultural colleges about a million dollars a year. If this amount, or more, could be annually devoted to a properly administrated series of "mono-technic" schools, suitably located, they would soon prove their worth and probably the larger industrial establishments would soon follow by joint effort in establishing additional ones. It is true that some beginnings have been made. At the universities of Pennsylvania and of Chicago the studies in political and social science have been given a commercial application, and at the State University of Ohio a special course of study has been put in operation covering the clay industries, but not including cement manufacture. All our mining schools fairly cover the theory and some laboratory practice of our various metallurgical operations, and this is usually supplemented by tours of inspection to large typical works.

Doubtless we have other similar beginnings towards the higher industrial and commercial education here contemplated, but we certainly have not yet set ourselves earnestly to solve this problem. It may be that the higher commercial schools and many of the "mono-technic" schools could best be established in connection with our various universities and engineering schools, and yet we seldom find them so connected where they have been brought to their highest development.

Our organized commercial bodies would seem to hold out the greatest promise of favorable auspices for the inauguration of such a system of "mono-technic" and commercial schools, not a single example of either of which is now found in this country. The problem is, however, not without its difficulties, and before anything is done or even recommended, the whole question should be looked into by a commission appointed preferably by the National Government through the Bureau of Education. Should not this society take the initiative in such a movement? I believe it should. I believe the future material prosperity of this country is very largely dependent on how we solve this problem. Let us remember that we can no longer judge of the future by the past; to-day both the successful manufacture and the sale of goods are reduced to exact sciences. Old things are done away and all things have become new. Let us see to it that our ship of state shall be guided by the lights which are now so successfully leading others through the channels of progress, rather than to continue to steer by the vanishing lights of a unique and tortuous past which may soon land us on the sandy banks of delusion and improvidence.

AN ELECTRIC COAL-MINING PLANT IN PENNSYLVANIA.*

The electric mining plant described is located in Westmoreland county, Pa., at Scott Haven, about 27 miles south of Pittsburg, on land owned by the Youghiogheny River Coal Co. This property includes about 5,800 acres, fully four-fifths of which lies on the west side of the Youghiogheny River. During the last 15 years operations have been extensively carried on and up to the present time about 750 acres have been mined. The several mines are scattered over the property, and were formerly operated by separate steam plants.

It was considered advisable by the company to change this and to adopt a method whereby any or all of the mining operations involved could be performed by power generated at and distributed from a central plant which would be capable of enlargement to meet the requirements for many years to come. Electricity was adopted and a location selected for the generating station, which was approximately in the center of the property, close to the Youghiogheny River. This selection was also influenced by its convenience to the main colliery office, its nearness to one of the mines and the fact that at that point was a large brick building which could be used for housing the machinery.

In this way the extreme distance eventually to be covered was limited to three miles in one direction, and four in the other. The present capacity of the power station was determined by considering the character and amount of machinery to be operated at the mines selected to be fitted up. This was as follows:

	HP.
Three locomotives, the average capacity of each being 1,167 short tons of coal, plus refuse, hauled about 1 mile per ten-hour day, say	150.0
Five pumps, of a total capacity of 800 U. S. gallons per minute	40.5
Three fans, of a total capacity of 270,000 cu. ft. of air per minute	105.0
Two screens (only one installed yet)	17.5
One machine shop	10.0
Twelve coal-cutting machines	152.0
Total full load of motors, HP.	475.0

The total number of motors was to be 29, including two on each locomotive, and the average was 18.2 HP.

The boiler plant as installed consists of six 125 HP. externally fired, horizontal, steel tubular boilers, 66 ins. in diameter and 18 ft. long, with 58 4-in. tubes. The working pressure is 100 lbs. per sq. in. These were arranged in two batteries of three each, with independent sheet iron chimneys 32 ins. in diameter and 60 ft. high. Each boiler delivers steam through a 5-in. pipe to a 12-in. header running the whole length of the boiler room. Feed water is taken from a 130-ft. artesian well, and from the pit of mine No. 1, the water from both being pumped into a 35,000 gallon mixing and settling tank. Fuel is hauled by mules on a timber trestle close to building and dumped into hoppers at the rear of the boiler room. There are four McEwen 150-HP. center-crank single-valve horizontal non-condensing engines, with automatic cut-off and cylinders 15 × 16 ins. These are placed in a line parallel to the backs of the boilers and are supplied with steam through 5-in. taps, which pass through the brick wall separating the engine from the boiler room. Exhaust steam is taken care of by a 10-in. pipe

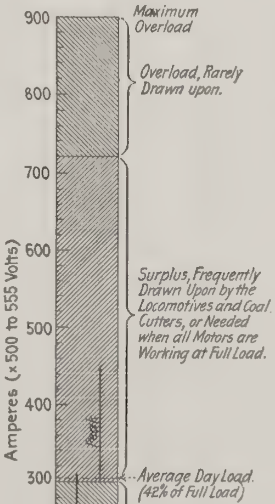

Diagram Showing Capacity and Loading of Power Station of the Youghiogheny River Coal Co., Scott Haven, Pa.

TABLE I.—Particulars of Mule versus Electric-Locomotive Haulage at Scott-Haven, Pennsylvania.

Main haulage.[1]	No. 1 Mine. Mules.	No. 1 Mine. Locomotive.	No. 2 Mine. Mules.	No. 2 Mine. Locomotive.	Pacific Mine. Mules.	Pacific Mine. Locomotive.
Number of mules or locomotives	12	1	12	1	15	1
Number of muledrivers or trainmen	3	2	4	2	5	2
Load hauled per day of ten hours, tons	740	1,000	1,090	1,450	600	1,000
Distance hauled,[2] ft.	5,300	6,500	5,400	5,400	5,400	5,400
Speed miles per hour	3.5	8	3.5	8	3.5	8
Mileage per day[2]	30	55	30	51	35	60
Number of trips made per day	30	25	....	27	....	30
Number of cars hauled per trip[3]	17	35	....	42	....	25
Gage, ins.	43.5	43.5	43.5	43.5	41	41
Weight of rails, lbs. per yd.	16	30 to 55	16	25 to 55	16	30 to 55
Weight of empty car, lbs.	1,100	1,100	1,100	1,100	1,100	1,100

*Abstract of a paper read by Mr. William S. Gresley before the Institution of Civil Engineers.

beneath the floor, which ends in a 500-HP. Hardwick feed-water heater.

The belt wheels of the engines are 64 ins. in diameter, with a 16-in. face, each engine driving through a 15-in. belt a General Electric 100-K-W. 4-pole railway generator running at 650 revolutions per minute. These machines have a no-load voltage of 500, and are over-compounded 10%, giving a full load voltage of 550, and will safely carry a 25% overload for 15 minutes. A suitable switchboard is arranged to permit parallel running, or almost any combination of generators and circuits.

In considering the question of transmission a 10% drop was allowed in feeders, the longest of which would be about 17,750 ft., although the average was 6,518 ft. The transmission lines are nearly all bare copper wires or cables supported on insulators and poles in the customary way, except that separate feeders are run in most cases for cutters, fans and pumps, each set using, however, a common return. Where it was necessary to cross the river, submarine cables were employed. In each case these were 550 ft. long, the sizes and use being as follows:

One cable 0.257-in. in diam. . .	Feeder for pump in No. 4 and South West mines.
Two cables 0.460-in. in diam. .	Feeders for locomotive, pump and fan at Pacific mine.
One cable 0.592-in. in diam. . .	Feeder for locomo., pump, fan and coal cutters in No. 2.
One cable 0.699-in. in diam. . .	Bunched return for all west side mines.

The overhead trolley with rail return is used for haulage, while power or light wires are hung along the tops and sides of tunnels, headings, drifts, or galleries. Daniel-Garton lightning arresters and switches are placed just outside pit-mouths or buildings containing motors. The mine equipments are much the same, and the following description of mine No. 1 will suffice for an understanding of all.

The track, 3 ft. 7½-in. gage, is of 30-lb. rails spiked to sleepers spaced 24 ins. c. to c. Where loaded trains are started the rails are 55 lbs. per yard. The locomotive has two 25-HP. enclosed motors geared to the two sets of 28-in. chilled cast-iron drivers. The motors are series-wound and are operated by a series parallel controller, the operator also having within easy reach the reversing lever, brake lever, etc. The locomotive weighs 10 tons, and has a draw-bar pull of 2,500 lbs. at a speed of 8 miles per hour. As operated it hauls 665 mine cars, containing about 1,000 tons of coal, with refuse, a distance of 6,000 ft. in 10 hours. Table I. affords a comparison of electric and mule haulage, showing the considerable saving resulting from the use of the former.

For drainage, a 6½ × 8-in. horizontal triplex Knowles' pump is geared to a 10-HP., 4-pole, shunt-wound, slow-speed motor. This pump is capable of raising 150 gallons per minute against a head of 150 ft. For ventilating, an 8×3½-in. Capell fan is belted to a 25-HP. multipolar motor. The fan runs at 625 revolutions per minute and discharges 75,000 cu. ft. of air per minute.

Table II. gives the particulars of the electric ventilating apparatus used at the Pacific mine and mines Nos. 1 and 2.

TABLE II.—Particulars of Electric Fan Ventilation at Scott-Haven, Pennsylvania.

Type of fan, Centrifugal; name, Capell.

	No. 1 mine.	No. 2 mine.	Pacific mine.

Mechanical efficiency, %	59	72	60
Fuel used per 24 hrs. in lbs. (estim.)	1,800	2,800	1,900
Approx. cost of fuel, cts.	20	31	21
Distance from power house. ft.	800	2,050	17,750

There are eleven Jeffrey chain coal cutters each driven by a 12-HP. motor. These work at an average distance from the power house of 9,700 ft., and during two shifts of nine hours each undermine about 800 tons of coal. To permit shifting about, each motor is provided with a reel holding 300 ft. of heavily insulated twin concentric cable. These machines cut through veins of a conglomerate of fragments of coal measure, often cemented together by iron pyrites, and this without any apparent damage to the cutters. Table III. affords a fair idea of the dimensions of these cutters and the various operating data.

TABLE III.—Data pertaining to Jeffrey Coal Cutters in Use at Scott-Haven, Pennsylvania.

Depth of cut made by machine	69 ins.
Width of cut made by machine	36 "
Height of cut made by machine	4 "
Weight of machine	2,800 lbs.
HP. of motor on machine	12 HP.
Area under-cut per run or cut	17 sq. ft.
Position of cut in the seam	A few ins. above the floor
Time occupied in making one cut	4.5 mins.
Power consumed when cutting	15.4 HP.
Power consumed when backing out of cut	2.8 "
Average number of cuts or runs made per shift	30
Number of shifts worked per day, about nine hours each	2
Tons (of 2,000 lbs.) produced per shift per machine	60 tons
Time occupied cutting	About three hours
Time occupied moving machine about, changing bits, etc.	About six hours
Average number of cuts made in each 21-ft. room	Seven
Number of bits or knives upon a chain	Forty-five
Weight cut per chain used up	35,000 tons (of 2,000 lbs.)
Production per man, by machines, per day	6 tons
Production per man, by pickwork, per day	4 "
Number of 21-ft. rooms apportioned to each machine per double shift.	24 rooms
Number of men operating each machine per shift	Two men
Fewer men employed where machines operate, or increased production per miner by use of machines	33%
Less pit room required where machines operate	33%
Output per machine per year	28,000 tons (of 2,000 lbs.)
Cost of blasting and loading up machine-cut coal	One-half pick-mining rate
Cost of under-cutting by machines	One-eighth pick-mining rate
Approximate saving by machines, including renewals, supplies, interest and depreciation, per 2,000-lb. ton	9 cts.
Proportion of machine-cut coal to total output in mines using machines	70%
Increased yield of lump coal due to machines	About 3%

The electrical apparatus installed displaced the following:

Forty mules on the main haulage lines; 12 mules working pumps or hauling water tubs; 20 men and boys driving mules, pumping and bailing; 6 men attending to ventilating furnaces; 3 steam pumping plants and 33% of the miners, where coal cutters are used. On the other hand, it was necessary to establish a mechanical department quite unlike anything existing in the old system. This is in immediate charge of a competent electrician, who is responsible for the working of the plant, and hence passes upon all men operating coal cutters and other mining apparatus.

Formerly, when coal was burned at 12 different places, 14 tons, valued at $5.60, were consumed each 24 hours, while at present the centralized plant consumes 17 tons of mixed slack and coal, at a cost of $3.75, in the same time, performing however, besides the pumping and ventilating, work formerly done by men and mules.

From a series of readings, taken every ten minutes during three working days, the average current for each of the five coal cutters in mine No. 1 was found to be 26.2 amperes, while the "repeated" maximum was close to 75 amperes. During this test separate generators were operating two locomotives, two fans, four pumps, and one screen, and records were taken of the current required by these. The plotted results form extremely irregular curves ranging all the way from 60 to 350 amperes, while fluctuations of as much as 100 amperes occur in a few seconds.

The station had, as a whole, at the time of the test, an average day load of close to 300 amperes, and an average weight load of about 140 amperes. The full capacity of the station is indicated by Fig. 1, which shows the average proportion of output furnished to the mining machines proper, the fans, pumps, etc., and the locomotives, and the height of the maximum peak belonging to each and apt to be called for at any time.

TRACK ELEVATION OF THE

The installation cost about $117 per HP. of engines; operating, stores and repairs cost about $25 per HP. per year, or about 3 cts. per ton of coal produced or delivered at the tips. It is estimated that the coal cutting portion of the outfit is paying about 50% on the original investment, the apparatus apart from this represents an investment paying about 25%.

Comparison between the old and new methods of mine haulage is given in Table I., a study of which, in connection with similar data, published in Engineering News of Feb. 24, 1898, will prove of interest.

* * *

TRACK ELEVATION OF THE ERIE R. R. THROUGH JERSEY CITY, N. J.

An important piece of track elevation work, which will include some unusual and specially interesting features, is the elevation of the Erie R. R., from the Jersey City terminal station to Jersey City Heights. The present railway crosses at grade all the streets from the river front back to the high bluffs under which the line passes by a tunnel, and it is only by the maintenance and operation of gates, more or less obstructive to the uses of the streets, that accidents are avoided. After long negotiations between the city and the railway authorities the latter agreed to elevate its tracks and thus eliminate all grade crossings.

In working out the plans, however, the railway included an important improvement by which the present Bergen tunnel through the Jersey City Heights will be avoided by its passenger trains. This tunnel is 4,381 ft. long, and the passage through it is a source of much discomfort in the summer, all the car windows and deck lights being necessarily closed in order to exclude the smoke and gas.

Besides this, all the passenger and freight traffic of the whole Erie R. R. entering the Jersey City terminal, including all the trains over the Erie's numerous suburban branches, are now compelled to pass through this tunnel. As trains are run through the tunnel on the block system, and no train is allowed to enter the tunnel until the train ahead has passed out of it, a fixed limit is set to the number of trains which can arrive or depart from the Jersey City terminal in a given time. During several hours of suburban travel in the morning and again in the afternoon, the tunnel is given up wholly to the use of passenger trains; and the freight traffic is stopped.

The plan adopted is to retain the present tunnel line for freight traffic only, and build a new passenger line in open cut across Jersey City Heights.

Figs. 1 and 2 represent the plan and elevation of part of the work proposed. Beginning at a point west of the terminal, the passenger tracks will rise for some 2,000 ft. to Henderson Street—the first street crossed. The freight yard branches will also grade up to the new elevation of the passenger tracks at Henderson Street. In all, six streets will be bridged over, to give a clear headway of 12 ft. The freight tracks, after crossing the last street, will grade down to the present elevation at the tunnel. About 2,400 ft. from the terminal, however, at a point just east of Grove Street, the two passenger tracks will begin to rise above the freight tracks (continuing parallel to them) by a grade of 46½ ft. per mile. This grade continuing up to the Heights, through which the line will pass in an open cut having a maximum depth of 36 ft. The tracks in the cut will be about 45 ft. above those in the tunnel, and the center lines of the cut and tunnel will be 85 ft. apart, as shown in Fig. 3. This new line is styled the Penhorn Creek R. R., and beyond the Heights it will descend to the present grade of the main line across the Jersey meadows.

For the freight tracks there will be vertical masonry retaining walls, with a solid earth filling between them, the width being from 100 ft. to 200 ft., the latter width taking in the entire block between 10th St. and 11th St. The walls will be of stone, with concrete foundations supported by piling. An enlarged section of the wall is shown in Fig. 6. The bridge abutments will be of generally similar construction. The piles are spaced 33 ins., 36 ins. and 45 ins. apart, c. to c., with a load of 16 tons per mile. Without the piles the pressure would be 1.8 tons per sq. ft. of foundation. Not all of the foundation are piled.

For the passenger tracks, a similar construction will be followed as far as Coles St., the width being 30 ft., but from that point to the Heights there will be a steel viaduct with 50-ft. plate girder deck spans, and plate girder and truss bridges over roads and railway tracks. The total length of this viaduct will be about 1,750 ft. Figs. 4 and 5 show the construction of the viaduct and bank, respectively. The viaduct will have two rows of columns, 28 ft. apart, c. to c., connected by longitudinal and transverse plate girders, the latter of which will support the four lines of floor beams. A footwalk is provided on each side, the total width over the floor of the viaduct being 35 ft.

When this work is completed, freight trains will run between Rutherford and the Weehawken yard, or the main freight yard or elevator at Jersey City, without using any track or switch used by passenger trains of either the main line or branches. The separation of the freight and the passenger traffic will then be absolute. Yard work is now in progress, the contract having been let in April, but the construction of the new passenger line will not be undertaken at present. The foundations will, however, be put in during the construction of the embankment and retaining walls, and the cut through the Bergen hill may also be excavated.

The north retaining walls and the north parts of the abutments will first be built and earth filled in to form a bank wide enough for the main tracks, so that the construction of the south walls and the south parts of the abutments can then be proceeded with. The excavation for foundations will be in some cases as deep, 10 or 12 ft. below the present surface, the material being paid for as excavation and being used for filling. The piles must be at least 8 ins. diameter at the small end, and 12 ins. diameter 3 ft. from the butt. The masonry will have a rock face. All cement is to be of leading American brands, cement mortar being composed of 1 part natural cement and 2 parts of sand. Natural cement concrete will be composed of 1 part cement, 2 parts sand and 4 parts stone. Portland cement concrete that will be laid under water will be of the same proportion, while that laid in air will be composed of 1 part cement, 3 parts sand and 5 parts stone. The north retaining walls, concrete pier, north parts of abutments and filling about 42 ft. wide, to carry three tracks, are to be completed by October, 1898, and all the work is to be completed by October, 1899. The contractors are Grattan & Jennings, of Buffalo, N. Y.

The plans were prepared by Mr. C. W. Buchholz, M. Am. Soc. C. E., Chief Engineer of the Erie R. R., to whom we are indebted for blue prints and specifications.

BOOK REVIEWS.

AUTOMIBLES SUR RAILS.—Par G. Dumont, Ingenieur des Arts et Manufacturers. Encyclopedie Scientifique des Aide-Memoire, M. Leaute, Directeur. Paris: Masson & Co. Paper; 7½ × 4⅝ ins.; pp. 184; illustrated.

This is practically a continuation of a previous publication of the same author on "Electromotors and their Applications." In his preface Mr. Dumont notes that the first application of a self-moving vehicle on rails, for ordinary street traffic, was that of Andraud and Tessie du Motay, who, in 1838-40 built a machine at Chaillot, France, operated by compressed air and seating eight persons. It worked well enough, but was not practicable. In 1848, a steam train, carrying 60 passengers, was worked for a time on some secondary lines near Bristol, England; and in 1859, steam tramways were successfully operated in the United States. In 1876-77 the English engineer, Grantham, introduced the first type of vehicle in which the steam motor was made a part of the vehicle itself, and in this same year, 1877, Mekarski established at Nantes the first public automobile service operated by compressed air. The first horse tramway in France was built in 1856, on a line extending from Paris to St. Cloud, and it was called the

"American" railway; but the first horse-car line in Paris itself was not in operation until 1875.

Mr. Dumont goes on to treat his subject under the seven heads of traction, by steam motors, by compressed air, by gas-motors, by carbonic acid and by ammonia engines, by cableways and by electric motors. Without going into the detail of each class it is interesting to the general reader to indicate how many methods have been proposed, and more or less successfully applied, for supplanting the horse on street and suburban lines of travel on rails.

Under the general head of steam motors we have the Rowan system of 1882, with vertical boiler and a motor beneath the carriage; the Serpollet system of 1887, in which instantaneous vaporization is secured by very thin boiler-tubes exposed directly to the fire; the steam turbine motor of A. Gerard, not yet actually in service; the Versailles-Maule system, which resembles the Rowan motor, but carries the motor-engine and boiler on a separate bogie-truck; the Lamm and Francq system, which omits the boiler and fire and carries a reservoir of hot water under pressure; and the Honigman system of fire-less boiler, in which the escaping steam is reheated by contact with very concentrated soda, and transmits this heat to the boiler and uses it again in the vaporization of water. Unhappily, the action of the soda upon the metal parts of the apparatus rapidly destroys them. Under compressed air motors, the author commences with the Mekarski system of 1877; he follows with the compressed air-motor of Hardie, tried in 1879 on the Metropolitan Elevated Railway of New York; the Scott Moncrieff motor of 1881; the Beaumont compressed air locomotive of 1885, and the Popp-Conti system, which differs from the Mekarkski device in using the air at a lower relative pressure. Motors operated by gas were introduced by Messrs. Banks and Baines in 1885, upon tramways in Australia. The first application was not successful, but it stimulated inventing in Germany, England, the United States and in France. The Luhrig system was brought out in Germany in 1893, upon the Dresden-Wildermann railway, 2½ miles long. Two Benz motors, of 7 or 8 HP. each, were operated by the explosion of gas, and the system is now quite generally used in Germany. Mr. Borig, of Berlin; Connelley, of New York; Pintch; Hasse; Holt & Crossley, of Manchester, and Grob, of Leipzic-Entrsch, have all patented devices for the application of gas to tram-motors. Mr. Barbet uses a mixed system of compresed air and gas; and Mr. Moutelar employs the first to start the train and then keeps up this motion by gas-engines.

Among petroleum motors the best known is the Daimler; but the Roger motor is being successfully tested in France. Motors operated by some very volatile liquid take their origin from the liquifaction of carbonic acid by Faraday, and the elder Brunel is credited with the invention of the first motor of this type. In 1835, Ghilliano and Christin, and in 1862, Marquis took out patents for carbonic acid motors; in 1891, Belzon, in Germany, actually built a carriage operated by a carbonic acid motor; and in 1892, "The New Power Co.," of New York, introduced a similar motor for street railways. In these motors the gas was carried in long, steel or iron bottles, generally under a pressure of 75 atmospheres, and was sent directly to the cylinders of the engine, where it was fired by a gas-jet. In 1821, Gurney advocated the use of ammonia as a producer of power, and in 1871, Dr. Lamm, in America, and Gen. Beauregard and M. Tellier, in France, made experiments promising success. In 1893, Mr. T. W. Morgan-Draper made an ammonia-engine, basing his system upon the property possessed by anhydrous ammonia of liquifying at about — 34° C., at the ordinary pressure, and at + 27° C., under a pressure of ten to twelve atmospheres: By heating a vessel containing liquified anhydrous ammonia to more than + 27° C., gases are emitted generating a tension of ten to eleven atmospheres, and this pressure is utilized in an ordinary engine. The escaping vapor is absorbed by water and the heat generated is utilized in heating the ammonia receptacle. At the New Orleans Exposition of 1893, Mr. F. F. MacMahon operated a motor of this type, weighing 7 tons, and capable of making a run of 24 miles.

Cable traction and electric motors, operated by both overhead, underground and interrupted conductors, are fully described by our author in separate chapters. The first application of electricity to street-car service in Paris was in 1881, at the Electrical Exposition of that year; but it was not until 1890 that an actual test was made by equipping a line, running between the Madeleine and Levallois, with the accumulator system. In 1892-93 similar lines went into operation, from the Opera House to St. Denis, and from St. Denis to Neuilly; in 1897 the system was further extended from Neuilly to Courbevoie, and from the Place de la Republique to Aubervilliers. A large part of this section of the work is devoted to the description of American apparatus, and this will not be repeated here. In his concluding chapter Mr. Dumont makes a comparison of the cost of operating the different systems of street-car traction described. This comparison, translated from the metric units, stands as follows:

	—Steam.—				Electric.	
Per car-mile	Rowan system.	Serpollet system.	Compressed air.	Gas.	Trolley.	Accumulator system.
Number of places for passengers	43	50	50	50	50	50
Weight fuel consumed, lbs.	10.6	9.0	15.3	58.2*	5.†	10.8
Operating cost:						
Motive force, cts	3.9	3.3	7.7	6.4	5.3	4.2
Wages, cts	2.6	2.6	2.6	2.6	2.6	2.6

Total expense,traction,cts.	14.8	13.1	18.6	16.7	15.6	15.2

---

* = cu. ft.

†This consumption of 5 lbs. of coal per car-mile is deduced from experiments made on the trolley lines of Rouen.

The above table is supposed to represent a typical system, 18 miles long, equipped with 30 cars, with a part of these held in reserve, and each car averaging a daily run of about 90 miles. In the items of wages paid and cost of materials, etc., no direct comparison is possible with American practice; but as the motive cost is the true standard of economy in the various systems of traction, some comparison can be made here. The reports of the Railway Commissioners of Massachusetts and New York, for 1897, show that the cost of electric motive power on the street railways of those states ranged from 2 to 3 cts. per car-mile, in the majority of cases, with some lines reducing this cost to one cent. This is in spite of higher wages paid; and the reduction in cost is wholly due to excellence of equipment, the longer lines operated, and to the valuable experience gained by American managers in the operation of electric railway systems. It is difficult to tell just what the "total expense of traction" in the above table does include; but in the case of the Massachusetts street railway system for 1896, the total expense of operation, as deducted from gross to obtain net earnings, was 19.7 cts. per car-mile; this average is for 1,277 miles of main track, averaging in cost $46,041 per mile, and of which 1,241 miles were operated by electric power.

AUTOMOBILES SUR ROUTES.—Par L. Perisse, Ingenieur des Arts et Manufactures. Encyclopedie Scientifique des Aide-Memoire, Paris. Paper; 7½ × 4½ ins.; pp. 206; illustrated.

This is a companion work to "Automobiles sur Rails," lately published by the same house and reviewed in this journal. The history of motor-vehicles for ordinary roads is taken up, from the steam-carriage of Cugnot, of 1770, and the author briefly describes the various English road motors which preceded and immediately followed the application of steam to railways. Mr. Perisse follows this historical portion with a general discussion of motors, transmission gear and accessories, and then describes the various types of motors designed for use on highways under the general heads of: Carriages for personal use; vehicles for common passenger transport, or omnibuses, and motors for carrying heavy merchandise. This is the valuable portion of the book, but the space here available forbids any adequate abstract. The conclusion of the author, resulting from a careful study of all existing methods of road-motor construction and practice are worth noting.

Mr. Perisse first points out the fallacy of the arguments usually advanced by the opponents of motors in comparing the power exerted with that of the horse and in ordinary vehicles. He claims that the results of all the recent motor-trials show that cost of traction is incontestably less with motors than with horses, notwithstanding the cost of fuel and materials. The one element still to be settled by long experience only is the expense of repairs and the daily cost in constant work with a motor. This is the question which the development of the motor can alone settle, by simplified mechanism and proper design in all parts of the apparatus. In comparing the various types of motors, he finds that the use of steam generally requires a heavy generator, when sufficient power is wanted; and the problem is one of weight and the employment of a clumsy fuel, with the added disadvantages of escaping hot gases and steam. The advantages are, the ability to vary the speed with steam pressure and to regulate the consumption of fuel by the amount of actual work to be performed. It is undoubtedly the motor for the transport of heavy loads, and devices are already in use for suppressing or mitigating any nuisance from smoke and steam. The steam-motor utilizes for adherence a part of the useful load.

Petroleum motors do not permit the regulation of the speed by the power produced, as in the case of steam. Mechanism, often very complicated, is necessary to bring about this change in speed. The petroleum motor also requires great care in its management, and the cost of traction is often very high, owing to the fact that the consumption of fuel is practically constant and independent of the work done. Under ordinary use there is great vibration of the body of the vehicle, resulting from the great speed of explosion-motors; and, finally, there is an objectionable odor from the burning oil, which may perhaps be eliminated by better construction. The advantages of the petroleum motor are that it may almost instantly be put into service; the fuel is easily handled; the dead weight of the vehicle is less than that of the steam-motor, and repairs are thus less costly. It is best suited for rapidly transporting passengers from one town to another; and it is the true tourist vehicle, for when speed is demanded, it can be secured even at less fuel economy. It may be applied to hotel omnibuses and to family coaches, but the useful load should never exceed about 3,300 lbs.

Electric motors present great advantages, as the traction is easy and regular, silent and unaccompanied by objectionable odors or steam. But the accumulator is heavy, cumbersome and of little capacity in proportion to the dead weight carried. In the present development of electric road-motors, it is difficult to foresee how these vehicles can be made to travel over a route of 36 to 60 miles. It is probably best adapted to city use, for comparatively short runs, and it may be sufficiently developed to supplant the cab-horse. As applied to omnibus service in England the results are not very promising.

◆

A TOWN IS TO BE MOVED on the Messaba range of Minnesota iron mines. The town of Eveleth has been in existence about four years, and has a population of 2,500, with hotels, banks, stores, etc. Late exploration has brought to light a bed of rich iron ore beneath this town that is valued at not less than $15,000,000, and the town must move on. The townsite proprietors had made stringent reservations in their deeds as to mineral rights, and they now offer all lot-owners in the western half of the town free lots in a better site eastward, with streets graded and sidewalks laid. They are now also seeking proposals for the wholesale removal of buildings on the ore tract. The owners of the land are Robinson & Flynn, Murphy & Dorr and E. M. Fowler, all of Detroit, Mich. They bought the land for the pine timber upon it, without dreaming of the wealth below the ground. They now receive about $300,000 annually in royalties upon the Fayal and Adams mines alone, says the Chicago "Tribune."

LETTERS TO THE EDITOR 121
- Errata in "De Pontibus"—Power of Windmills.

THE CHICAGO SEWER DISTRICT, lying between 79th, 106th and Halsted Sts. and the lake, known as the 95th St. low-level district, has recently been a subject of controversy. This district was shown on the map in our issue of April 21, and, as described in the article on the intercepting sewer system, it has an area of about 10,800 acres. It was proposed to put in about 122,187 ft. of brick sewer, 2½ to 13½ ft. in diameter, leading to a pumping station on 95th St., from which the sewage would be raised and discharged through an outfall into the Calumet River. This river is already a foul stream which pollutes the water of the lake, and it is urged that the pollution should be checked instead of being increased by the sewage from the 95th St. district. Two plans for the latter purpose have been suggested: (1) to connect the sewer system of the district with the new intercepting sewer system; (2) to connect it with the Drainage Canal by means of a channel striking the canal at "the Sag." The latter plan is the one generally favored, and both the Mayor and the Commissioner of Public Works are opposed to any further discharge of sewage into the lake. After a public hearing, at which the property-owners sustained the position of the authorities, the engineers of the sewer department were directed to prepare new plans, providing for carrying the sewage to the Drainage Canal.

◆

A CALUMET RIVER DRAINAGE CANAL is now being planned by the direction of Mr. L. E. McGann, Commissioner of Public Works, of Chicago. The river now flows into the lake, but as it carries a great quantity of sewage and filth from packing houses, etc., it is a source of serious pollution to the city's water supply from the southern intakes. The proposition to discharge the sewage of the 95th St. sewer district into the river has called attention to the present state of affairs, and measures are to be taken to treat the Calumet River like the Chicago River, and reverse its flow, giving a flow westward from the lake into the Chicago Drainage Canal. The general plan is to build a canal about 100 ft. wide and 14 ft. deep, from Lake Calumet along the course of the Little Calumet River to the point on the Drainage Canal known as "the Sag," a distance of about 15 miles. This would have a capacity of 300,000 cu. ft. per minute, and would serve as a feeder for the Drainage Canal. The cost is estimated at $3,000,000. Should there be any objection to this plan, the Calumet canal could be connected with the Illinois & Michigan Canal. A special drainage district may be organized, with a Board of Trustees to carry out the work, but the Commissioner of Public Works hopes that the U. S. Government will take the matter up and build a navigable canal from the mouth of the Calumet River to the Drainage Canal, thus giving a route by which vessels can avoid the detour through the Chicago River. The general plans for the new canal are to be prepared by Mr. John Ericson, City Engineer; Mr. F. E. Davidson, Superintendent of Sewers, and Mr. Wm. Lowe and Mr. Hill, Engineers of the Sewer Department.

◆

THE CAMBRIA STEEL CO., a new corporation, is about to absorb the Cambria Iron Co., of Johnstown, Pa. The new company is to have a capital of $24,000,000, and the Iron Co. is guaranteed 4% dividends and the stockholders may subscribe for three shares in the new company for each of the Iron Co.'s shares held. The Cambria Iron Co. has been in existence nearly 50 years and has a capital of $8,000,000, with assets of $29,000,000 at current low valuations. The works have outgrown this capital and the new company has been formed.

AMERICAN STEEL FOR BELFAST SHIPYARDS is an import that is causing concern among Scottish steel makers, says "The Engineer." The firm of Harland & Wolff, of Belfast, is credited with a consignment of 800 tons of large steel ship-plates from Pittsburg. These plates are 28 × 5 ft. and weigh 2 tons each, and are supposed to be landed at Belfast from $2.40 to $2.88 per ton less than if bought from Scotch or British makers. This Belfast firm consumes in shipbuilding about 40,000 tons of steel and 8,500 tons of iron per year, besides using in this time about 60,000 tons of other materials. The existence of a fine line of steamers running between Belfast and the United States, and the advantages of the rapid delivery of large quantities of steel at low prices, are supposed to account for the demand upon American steel manufacturers. In years past almost the whole of the steel used in the Belfast yards came from the West of Scotland; increased consumption calls for additional supplies from the East Coast, Wales, Barrow and America.

◆

THE RUSSIAN BATTLESHIP which the Cramps, of Philadelphia, are to build will have a displacement of 12,700 tons, and will be able to maintain a speed of 18 knots for 12 consecutive hours, with all coal, ammunition and stores aboard. She is to be superior to any class of battleship now afloat; and the new United States battleships should be her equals, at least. If our builders can furnish other nations with the best vessels of this class in existence, it would be worse than folly to talk of providing inferior warships for our own navy.

◆

THE CONDITION OF ADMIRAL CERVERA'S SHIPS is reported upon as follows by the Chapman-Merritt Wrecking Co.: The "Vizcaya" and "Almirante Oquendo" are total wrecks, not worth saving for junk. The "Maria Teresa" has a hole 15 ft. long in the bottom close to the keel; this is being patched up and she will be first taken into Santiago harbor, and then possibly to Havana to be further fixed up for her journey north. The "Christobal Colon," says Capt. Smith, of the wrecking company, is in such a precarious position that he has little hope of saving her. The "Reina Mercedes," in Santiago harbor, can be easily floated.

◆

THE EIGHT-TRACK DRAWBRIDGE over the Chicago Drainage Canal will be a Scherzer rolling-lift bridge, the contract having been awarded to the Scherzer Rolling Lift Bridge Co., of Chicago, Ill., at its bid of $369,140, exclusive of the operating machinery. The sum of the bid was made up as follows: Plans, $27,000; substructure, $166,575; superstructure, $175,565. The list of bids was given in the supplement of an issue of Aug. 4, and we expect to describe the bridge in a later issue.

◆

A SIX-TRACK DRAWBRIDGE, on the Scherzer rolling-lift system, is to be built for the New York, New Haven & Hartford R. R., to carry the tracks of the new terminal station at Boston, Mass., across the Fort Pond channel. The plans were made by the Scherzer Rolling Lift Bridge Co., of Chicago, and the contract for construction has been let to the Pennsylvania Steel Co.

◆

THE MOST SERIOUS RAILWAY ACCIDENT of the week occurred Aug. 21, on the Providence Division of the New York, New Haven & Hartford R. R., at Sharon, Mass. The accident was a rear-end collision between two passenger trains, and according to reports resulted from the failure of a signal light to work properly. Four persons were killed outright, one seriously injured and 12 or 15 were more or less seriously injured.

◆

A LOCOMOTIVE BOILER EXPLOSION occurred on Aug. 17 in the round house of the Santa Fe, Prescott & Phoenix R. R., at Prescott, Ariz., resulting in the death of two and serious injury of two others. The report states that the firebox and part of the boiler, weighing four or five tons, was blown about 1,200 ft.

◆

THE FALLING OF A PORTION OF THE SIDEWALL of the Carnegie Tunnel on the Chartiers division of the Pittsburg, Cincinnati, Chicago & St. Louis Ry., at Pittsburg, Pa., on Aug. 22, killed 8 men, seriously injured 7 others, two of whom will probably die. The men were part of a force engaged in tearing out the tunnel and were preparing to pull down the west wall when, without warning, the wall fell forward, burying those standing in front.

◆

THE LONDON WATERLOO AND CITY ELECTRIC Underground Railway is now formally opened to traffic, from the Waterloo railway station to the Mansion House, a distance of 1½ miles. This distance is run in five minutes for a fare of 4 cts., or 6 cts. for a round trip. The cars have a central passageway, and they are equipped with Westinghouse air-brakes and are lighted by electricity. An electric third-rail system permits a maximum speed of 25 miles per hour.

AN AMERICAN LOCOMOTIVE FOR ENGLAND, recently built by the Baldwin Locomotive Works, Philadelphia, Pa., is a narrow gage tank engine for the Lynton & Barnstaple Ry., having a gage of 23½ inches. The engine has side tanks and a rear coal bunker behind the enclosed American cab. It has outside cylinders 10 × 16 ins., driving the rear pair of coupled axles with wheels 33 ins. diameter, and under each end of the engine is a pony truck with 22-in. wheels. The weight is 46,000 lbs., of which 29,000 lbs. are on the driving wheels.

◆

THE AMERICAN MAIL STEAMSHIP CO., launched, on Aug. 18, the "Admiral Dewey," the first of the four steamships being built for this company by the Cramps, of Philadelphia. Each of these steamers will be 280 ft. long, 36 ft. beam and 25 ft. depth of hold, the tonnage is 2,000, and a speed of 15 knots is specified. They are twin-screw steamships with triple-expansion engines. The "Admiral Dewey's" keel was laid on May 25, and her hull has consequently been built in about 11 weeks. The contract called for her delivery, complete in all parts, during the month of October.

◆

A JAPANESE SHIP-CANAL is under consideration. It would connect Osaka Bay, on the Pacific side, with the Sea of Japan, by way of Lake Biwa. This lake covers 46% of the length of the line. Including the lake, the length of the canal would be about 75 miles. The estimated cost ranges from $70,000,000 to $150,000,000, and the time of execution from 10 to 15 years.

◆

ONLY ONE BIDDER FOR A NEW WATER SUPPLY for Jersey City responded to the call for bids on Aug. 18. Mr. Patrick H. Flynn, of Brooklyn, submitted two formal propositions, each for water from the Rockaway River, delivered by gravity at an elevation of 210 ft. above mean high tide. The prices under each plan for a plant capable of delivering 50,000,000 gallons a day were about $7,500,000, or about $8,000,000 for a 70,000,000-gallon plant. If the plant should not be purchased until some years after completion the price would be considerably higher. The prices for water by the million gallons ranged from $36 to $20, for quantities varying from 25,000,000 to 70,000,000 gallons per day. Mr. Flynn was one of four bidders last February, and his bid is higher now than then.

◆

BIDS FOR 16 TORPEDO-BOAT DESTROYERS and 12 torpedo boats were opened at the Navy Department, Washington, D. C., on Aug. 23. The specifications were that the destroyers should be of about 400 tons, and should cost not to exceed $295,000 each, with a speed of 28 knots; while the torpedo boats were limited to 150 tons and $170,000 each, with a speed of 26 knots, making a total of about $6,900,000, the amount appropriated for this work. The bids received were in most cases for one, two or three boats, and all were within the figure set by Congress. As a large number of bids were received and as estimates were asked on two propositions, one as planned by the department, the other based on the bidder's idea, it will require some time to sort and tabulate the bids received, which will be necessary before awards can be made. One firm offered to build destroyers with a speed of 40 knots. Neither Cramps nor Hereschoffs presented bids.

◆

RULES FOR APPOINTMENT to the Corps of Civil Engineers, U. S. N., have been issued by Commodore Endicott, Chief of the Bureau of Yards and Docks. The applicants must be 25 years and not more than 35 years old. A naval medical board will examine them as to physical fitness, and a board of officers appointed by the Secretary of the Navy will examine applicants as to their mental and professional qualifications. Each applicant must give evidence of American citizenship and apply to the Secretary of the Navy for a permit to be examined. As to professional qualifications, there must be evidence of having received a degree of civil engineering from some professional institution of good repute, and a record of at least three years' practical experience as a civil engineer. The mental and professional examination will be competitive and in writing. It will comprise the following subjects: Testimonials; English grammar and composition; elementary physics; elementary geology; analytical geometry; differential and integral calculus; applied mathematics, including mechanics of solids and fluids and strains in structures; construction materials; engineering construction; topographical, trigonometrical and hydrographical surveying, and mapping; instruments and their use and adjustment. To pass a satisfactory examination candidates must attain an average of at least 80% in applied mathematics, construction materials and engineering construction, and a general average of 75%. An examination will be held on Sept. 6 at the Navy Yard, Washington, D. C., at 10 a. m.

◆

AN OBSERVATORY ON PIKE'S PEAK is to be built by the Manitou & Pike's Peak Cog Ry. Co., and the contract has been signed for the construction of the tower. It is proposed to mount in this tower four powerful telescopes for the benefit of visitors—and the profit of the railway company.

I E 1,500-HP. ENGINES FOR THE BERLIN, GERMANY, ELECTRIC WORKS.

We illustrate in the accompanying cuts the general details of the two new engines built by the Goerlitz Machine Works, of Goerlitz, Germany, for the Berlin Electrical Works, the company operating the five central lighting stations of Berlin, Germany. These two engines are exactly alike, and, as will be seen from the general view, Fig. 1, they are cross-compound engines with the cylinders supported on vertical cast-iron A-frames. The cranks are set 108° apart and the hollow shaft is 15.75 ins. in diameter at the bearings. For convenience and to avoid the possibility of a complete shut down, this crank shaft is made in two sections, the adjoining ends of which are provided with solid flanges which are bolted together. There are four ample bearings, one on each side of each crank.

The high-pressure cylinder is 36.61 ins. in diameter, the low pressure 57.09 ins. and the stroke is 43.31 ins. With a steam pressure of 10 atmospheres (about 150 lbs.) and a speed of from 105 to 110 revolutions per minute the nominal horsepower is 1,500, although the engine can be worked up to 1,900 HP. Both cylinders are jacketed with live steam.

The steam for operating the engine passes from the boilers through the main steam pipe and valve into the high pressure receiver HR (Fig. 3). From the receiver it enters the high pressure cylinder at the proper time and exhausts into the low presure receiver LR, from which it in turn passes into the low pressure cylinder and thence through the exhaust pipe to the condenser.

The valve mechanism, known as the "Collmann," after its inventor, is operated by two sets of bevel-gears just outside the bearings G G, and two vertical rods which run up alongside the cylinders and drive continuously through spiral gears and a short horizontal shaft. This shaft is provided with eccentrics and bell cranks, which operate the rods controlling the 8 poppet valves, four of which, a, b, c, d, are shown in Fig. 2. The governor is placed on an extension of the high pressure driving rod, Fig. 3. It is of the usual fly-ball type with dash pot and a system of links and levers which adjusts the admission for the high pressure cylinder. The exhaust of the high pressure and valves of the low pressure cylinder are fixed and do not vary with the load.

The crossheads are keyed to the piston rods and are provided with a slide plate which bears against a flat slide guide on one side only of the A-frame. The connecting rod is of the ordinary marine Y type and straddles the crosshead.

The air pumps are operated by levers supported by offsets bolted to the A-frames and connected to the crossheads by suitable links. The diameter of the air pump cylinders is 32.48 ins. and the stroke is 9.45 ins. The jet condenser is fitted with main and auxiliary injectors, the latter being supplied from a cold water tank, and is used only when starting up to avoid disturbing the condensers of other engines which feed from the same water main. The main injector is opened and the auxiliary closed when the engine is running smoothly.

At each end of the engine and mounted directly upon the shaft is the field of a 700 K-W. 3,000-volt alternating generator. These fields are heavy and serve as balance wheels to steady the engine. The specifications required that with a sudden change of load of 25% the speed should not vary more than 1½%, and that the variation should not be greater than 3% when the full load was thrown off or on. As will be seen from Fig. 1, the various operating valves are conveniently placed at the front within easy reach of the engineer. Lubrication is accomplished from a central point, the "Ritter" system being employed. We are indebted to the "Zietschrift des Vereines Deutscher Ingenieure" for the matter from which this description and the illustrations have been prepared.

BRIDGE WORK ON THE KANSAS CITY, PITTSBURG & GULF R. R.

(With two-page plate.)

In the description of the Kansas City, Pittsburg & Gulf R. R., published in our issue of Feb. 17, we promised to give some further information respecting the bridge work on the line. In the present article we describe more particularly three specially interesting features of this work: (1) The Waddell patented form of 100-ft. through truss; (2) the concrete piers of the Arkansas River bridge; (3) the construction of these piers, with the engineering difficulties encountered and overcome.

From the tabular statement given in the former article it will be seen that the bridge work on the main line, 788 miles, amounts to 92,288 ft., or about 17.5 miles, as follows: Timber trestles, 83,462 ft.; truss bridges (including 1,471 ft. of the Arkansas River bridge), 5,927 ft.; plate girders (50 and 60-ft. span), 1,695 ft.; I-beams, 1,204 ft. Mr. Robert Gillham, M. Am. Soc. C. E., M. Inst. C. E., is Chief Engineer and General Manager, and Mr. J. A. L. Waddell, M. Am. Soc. C. E., was Consulting Bridge Engineer.

Steel Superstructures.

Plate Girders.—The plate girder bridges are of two standard lengths, 50 and 60 ft. span, both of which are deck bridges. The 50-ft. spans are 5 ft. deep, with web plates ⅜ × 59¾ ins., and top and bottom chords, each composed of two 66-lb. angles, 6 × 6 ins., and a cover plate ½ × 16 ins. The stiffeners are 24-lb. angle irons, 3½ × 3½ ins., those at the ends having fillers 9-16 × 4 ins., while all the others are crimped. At the middle of the span are inside and outside splice plates ⅜ × 12 ins. The rivets are of soft steel, ⅞-in. diameter. The girders are set 6 ft. apart, c. to c., and connected by four bracing frames, riveted to ⅜-in. connection plates. The two end frames have four 24-lb. angles (top, bottom and two diagonals), 3½ × 3½ ins., while in the two intermediate frames the bottom angle is omitted. A ⅜-in. plate is riveted at the intersection of the diagonals. There is also a single system (non-intersecting) of top lateral bracing of angles of the same size, also riveted to connection plates. At the sliding end, a 1¼-in. bearing plate, 20 × 20 ins., is secured to the bottom chord by countersunk rivets, and rests on a ½-in. bed plate, 21 × 21 ins. The anchor bolts are 1¼ ins. diameter, and the bolt holes in the bottom chord are slotted ½-in. on each side of the bolts to allow for expansion. The live load is Waddell's "Class X," and the dead load is 900 lbs. per lin. ft.

The 60-ft. girders are 6 ft. deep, with web plates 7-16 × 71¾ ins.; chord angles, 6 × 6 ins., 72 lbs.; cover plates, ⅝ × 16 ins., 42 ft. long; top lateral bracing, 30-lb. angles, 4 × 4 ins. The stiffeners, splice plates, and bracing frames are similar to those in the 50-ft. spans, but there are three intermediate frames. The girders are set 7 ft. apart, and the dead load specified is 1,000 lbs. per lin. ft.

Waddell's "A-Type" Truss.—This is a decidedly interesting style of truss, the designs for which have been patented by Mr. Waddell. It is a four-panel truss bridge, having eye-bars in the bottom chords and center verticals, and rigid members for all the other portions of the trusses and for the lateral system. In his "De Pontibus," Mr. Waddell states that for a number of years he was dissatisfied with all railway bridges for spans between the superior limit of the plate girder and a length of about 150 ft. He considered that ordinary through Pratt trusses were too light and vibratory, and that riveted bridges as then built were clumsy, unscientific and uneconomical. In 1893, when he was retained by the Kansas City, Pittsburg & Gulf R. R. to design some bridges, he persuaded the General Manager to have a "type A" truss of 100 ft. span built as an experiment, and this style of structure was soon afterwards adopted as the standard 100-ft. span of that railway. These bridges are also used on the St. Louis Southwestern Ry., and have been adopted by the Nippon Ry., of Japan, for spans of 65 ft. to 116 ft. The advantages claimed for this type of bridge are great rigidity in all directions, ease and cheapness of erection, and economy of metal when structures of this type are compared with structures of other types having equal strength and rigidity.

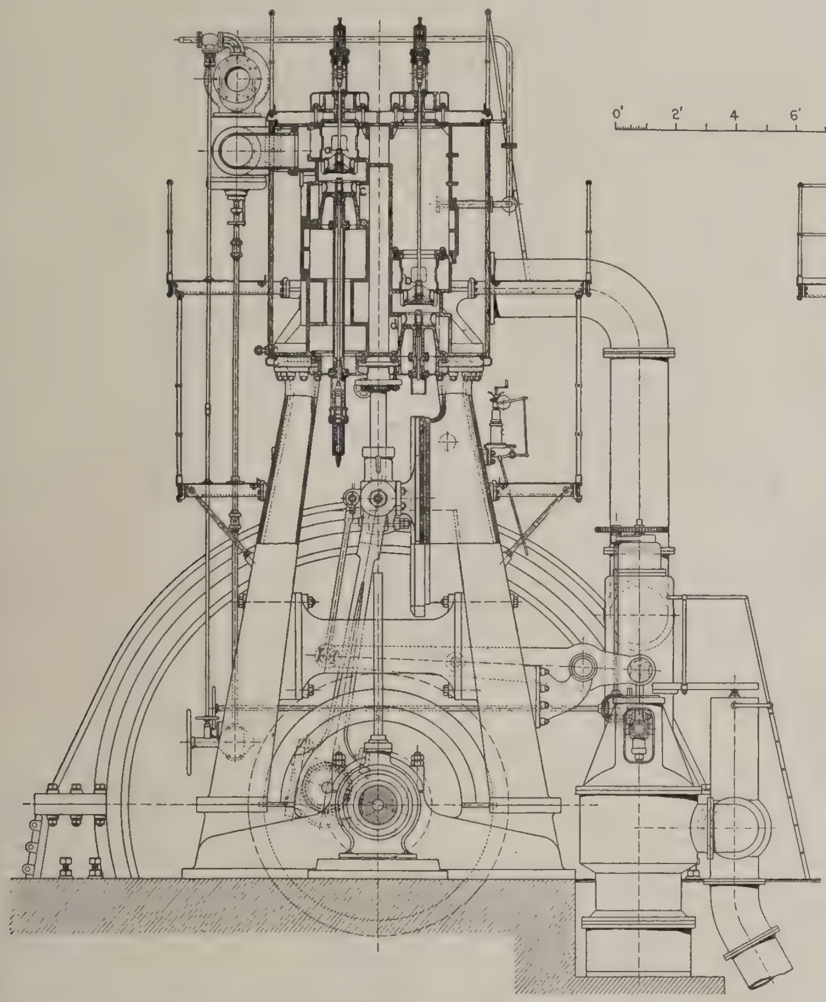

FIG. 2.—SECTIONAL END ELEVATION SHOWING DETAILS OF HIGH PRESSURE VALVES, CROSSHEAD AND AIR PUMPS.

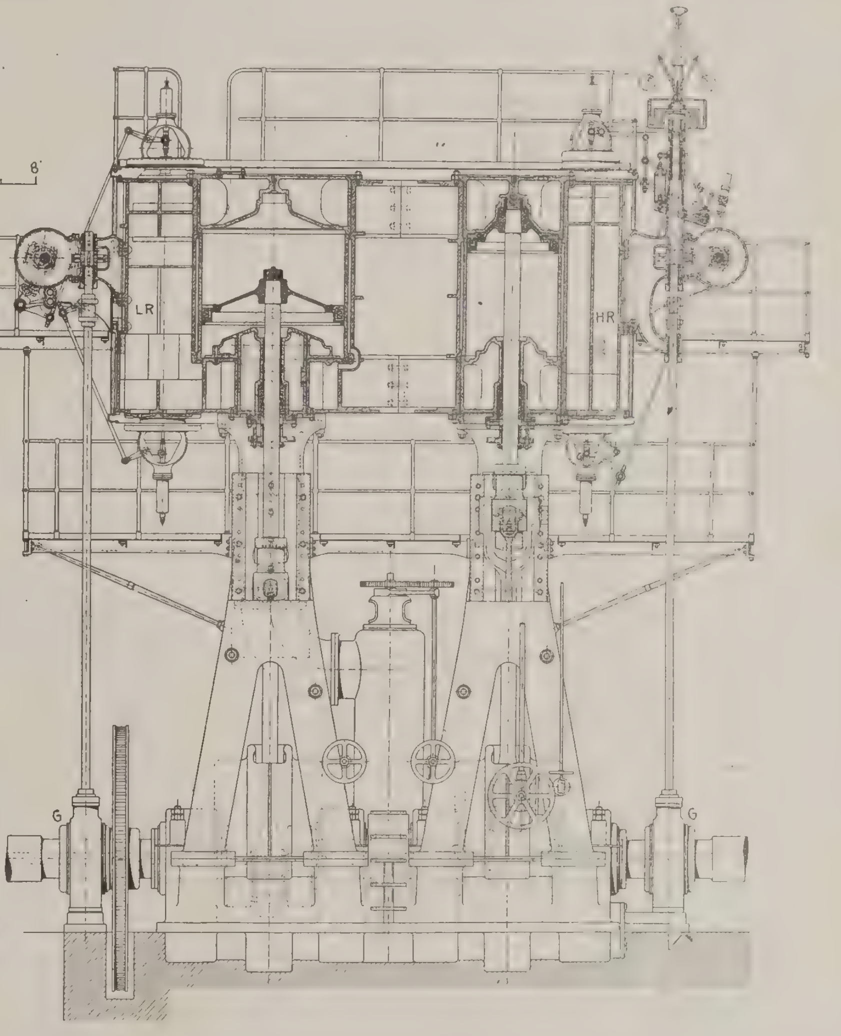

FIG. 3.—SECTIONAL FRONT ELEVATION SHOWING DETAILS OF CYLINDERS, RECEIVERS AND VALVE MECHANISM.

The 100-ft. spans of this type on the K. C., P. & G. Ry., are triangular trusses, 100 ft., c. to c., of end pins, and 40 ft. high at the center, as shown in Fig. 1. Each inclined top chord is built up of a cover plate ⅜ × 18 ins. (6.75 sq. ins. section), and two 15-in., 96-lb. channels (19.2 sq. ins.), 11 ins. back to back, laced below with bars ⅜ × 2½ ins. The bottom chord is composed of pairs of 1 × 5-in. eye-bars, 25 ft. long (10 sq. ins.), while the center vertical is composed of two eye-bars 1¼ × 5 ins. (12.5 sq. ins.). Each of the other two verticals is composed of two 10-in., 57-lb. channels (11.4 sq. ins.), set back to back 10 ins. apart, and connected by lacing bars ⅜ × 2 ins. The two diagonals are each composed of 10-in., 60-lb. channels (12 sq. ins.), 7⅝ ins., back to back, with similar lacing. The end pins are 5 ins. diameter, and the other pins all 4 ins. diameter. Fig. 1 shows the general elevation and plan of the bridge, while Fig. 2 shows the composition of the trusses.

The trusses are 17 ft. apart, c. to c., connected by top transverse struts at the three panel points, with diagonal bracing between these. The clear headway is 21 ft. 2 ins. Plate-girder floor beams, 4 ft. deep, are fitted between the bottoms of the three verticals, projecting but little below the bottom chord. These carry plate girder stringers 38 ins. deep, spaced 8 ft. c. to c. Horizontal and vertical bracing is fitted between the stringers, and the ends of the floor beams are also connected by diagonal bracing. The middle floor beam is riveted to hangers of two 10-in., 57-lb. channels, 10 ins. apart, connected by bracing, attached to the eye-bars by 4-in. pins.

The floor system consists of yellow pine ties, 8 ins. wide and 10 ins. deep, spaced 5 ins. apart in the clear and boxed out ½-in. over the chords of the stringers. Most of the ties are 10 ft. long, but every fourth tie is 14 ft. long, the ends supporting two foot planks 2 × 10 ins. Inside 60-lb. guard rails are used, 5 ins. from the track rails. There are also heavy outside guard timbers, 8 × 10 ins., laid flat and boxed out 2 ins. over the ties, which is an unusual depth of boxing, and is intended to prevent bunching of the ties by derailed wheels. These timbers, which are 8 ft. c. to c., are bolted to every tie, the ¾-in. bolts being in two staggered rows, and having ogee washers on top of the guard timbers.

The dead load is assumed as 1,400 lbs. per lin. ft. The live load is Waddell's standard loading, Class X, the equivalent uniform load per lin. ft. being as follows: 4,000 lbs. for trusses, 4,600 lbs. for floor beams, and 5,750 lbs. for stringers. The camber is such that under a live load of 4,000 lbs. per lin. ft. there will still be a camber of at least ¼-in.

Through Truss Bridges.—The through bridges of 127 ft. and 150 ft. span are of interest in that the trusses have riveted connections instead of pin connections, as shown in Fig. 3. The inclined end posts and top chord are composed of two 15-in. channels, set back to back; the end posts have a cover plate on top with lacing on the bottom; while the chord has top and bottom lacing. The bottom chord and end verticals are of H section, built up of four angles with transverse stay or batten plates at intervals. All the other truss members are composed of two channels set face to face, and connected by lacing. Connection plates of ample area are used at all panel points, as shown, and knee braces connect the top lateral struts with the posts. The floor beams are plate girders 4 ft. deep, resting on angle brackets on the posts and riveted to the posts. The rail base is 4 ft. 4½ ins. above the center line of the bottom chords. The trusses are 28 ft. deep, c. to c. of chords, and have panels 25 ft. long. They are set 17 ft. apart c. to c., and have a clear headway of 21 ft. 6 ins.

The 200-ft. spans have pin-connected trusses. Special features of these trusses, as of the other trusses, are the substantial character of the design, the heavy floor beams and overhead bracing, and the substantial design of the connections.

All the material is of medium steel, put together with ⅞-in. soft steel rivets, except that ¾-in. rivets are used in some of the angles and lacing bars. The truss members were assembled in the shops and had the rivet holes reamed to a perfect fit. The rivet holes were punched ⅛-in. smaller than the rivets and then reamed to a diameter 1-16-in. greater than that of the rivet. The ends of all stringers and floor beams, and of all abutting members, are planed, so as to have a perfect contact. The metal work was given one coat of paint at the shops and two after erection in the field. The general particulars of 150-ft. and 200-ft. spans are as follows, the loading being all per lin. ft. of span and the live loads being Waddell's Class X:

Length, c. to c. of end pins	150 ft. 0 ins.	200 ft. 0 ins.
Panel length	25 " 0 "	28 " 6⅞"
Truss depth at center	28 " 0 "	37 " 7 3-16
Distance between trusses, c. to c.	17 " 0 "	17 " 0 ins.
Clearance above rail base	21 " 6 "	21 " 6 "
Dead load for trusses	1,700 lbs.	1,920 lbs.
Dead " floor system	700 "	700 "
Live " trusses	4,140 "	4,020 "
" " floor beams	4,900 "	4,720 "
" " stringers	5,925 "	5,720 "
Wind load for top lateral system	150 "	200 "
Wind load, bottom lateral system	450 "	500 "

Arkansas River Bridge.—This bridge, shown in Fig. 4, is the longest on the line, aggregating 1,471 ft. It has a through truss channel span of 250 ft., flanked on the north by five deck trusses (4 of 127 ft. and 1 of 147 ft., c. to c. of end pins) and a plate girder of 50 ft. span. On the south there are three deck trusses of 147 ft. and a plate girder of 50 ft. span. The high water elevation is 31 ft. above low water elevation, and the base of the rail is 60 ft. 6 ins. above low water.

Concrete Piers; Arkansas River Bridge.

The ten piers and two abutments of the bridge over the Arkansas River are all built of monolithic concrete, and in the construction of the piers numerous difficulties were encountered. The following table gives the dimensions and cubic contents of the piers:

Concrete Piers of the Arkansas River Bridge; K. C., P. & G. R. R.

No.	Height, ft.	ins.	Length and breadth—At base.—ft. ins. × ft. ins.	At top.—ft. ins. × ft. ins.	Low water, cu. yds.—Above.	Below.

Mr. A. M. Nelson was engineer in charge of construction at this bridge, and in a report made to Mr. Robert Gilham, the Chief Engineer and General Manager, he gives an interesting account of the methods of construction, and the methods of overcoming the difficulties. An abstract of this report we give below, believing it to be of special interest and value. It should be explained that abutment A and pier No. 1 are at the south end of the bridge, the enumeration running from south to north. Fig. 5 shows the details of these piers and abutments:

Surveys.—The positions of the piers were determined by triangulation, for which four independent base lines were used. On the south side of the Arkansas River a perpendicular was erected, extending 1,500 ft. east and 1,272 ft. west of the center line. From this double base line the distance across the river was calculated, and checked by calculation from another line thrown off at random from the bridge tangent, at a point that afterwards proved to be 10 ft. 1 in. south of the center of pier No. 8. This measurement was subsequently checked again by another line thrown off at right angles to the center of pier No. 10, and extending 2,000 ft. to the east.

Several points were established on each of these base lines, and angles read to and from each of these points, all of which were read and re-read 20 times, giving direct interpolation of the angle to within 3 secs. From this close reading of the angles, and the accuracy with which the base lines were measured, the various calculations checked within 0.026 ft.

The base lines were measured in the following manner: We first used an ordinary 100-ft. steel tape line, supported at intervals of 25 ft. upon the tops of stakes which were driven to a perfect level. This measurement was afterwards checked with a wooden rod 20 ft. long, and measured to knife blade scratches.

At corresponding distances from the triangulation points and the tangent—that is, distances corresponding to the distances from the initial point to the centers of the piers—piers were staked out on these base lines, so that before the construction of the piers progressed far enough to obstruct the view, cofferdams and cribs could be set by direct sight. In all cases when it was impossible to see across the river to any point, the angles could be turned so that a right angle intersection could be made on the direct points in the stream, locating the exact center or points corresponding to the points used on the shore. These angles were all of 45°, thus making it unnecessary at any time to have to refer to field notes, or for any purpose carry maps or plans or notes of the survey into the field. At any time, and under any circumstances or conditions, points could be given by direct intersection from some of the number of base lines established.

The masonry was begun on both sides of the river, and when all the piers were completed and the falsework placed in position, so that direct measurements were obtainable, the measurements checked out as close as it was possible to measure, illustrating the care and accuracy with which the former work had been done. All points on shore were additionally referenced with hubs and guard stakes, so that at low stages of the water the points for piers Nos. 3, 4 and 5 could be easily established from these intermediate references.

In addition to this, we placed at right angles from each of the three above-mentioned piers, range stakes, to enable the contractors to float their cribs and cofferdams into position without having to wait for the engineer to give them lines or points. These ranges were so arranged that the intersection of the lines would bring them in direct position and could be used by the contractor's foreman by day or by night.

The triangulation points, ranges and all other points were preserved without very much difficulty through the construction of the work.

Concrete.—On June 17, 1895, the Arkansas Construction Co. entered into a contract with McGee, Kahmann & Co., of Kansas City, Mo., for the construction of the piers. Work was to be commenced immediately and completed by Oct. 1, 1895. The 10 piers and 2 abutments were to be built of Portland cement concrete according to plans and specifications furnished by the Arkansas Construction Co. The concrete was composed of 1 part Portland cement, 2½ parts of coarse sharp sand, and 5 parts of clean broken stone. The sand and stone were found on the site of the bridge. The cement was to be of the best quality of hydraulic Portland cement. Although the Arkansas Construction Co. showed a preference for North's Portland cement, no first-class brands were barred. Subsequently two brands of cement were used, North's Portland (Condor brand) and Kelley Island Cement Co.'s Lagerdorfer (Tower brand), both filling the requirements of our specified tests, and giving good results in the work.

The contractors moved onto this work about July 1, and began the preliminaries, although no actual construction was done until Aug. 22, when the first concrete was mixed and placed in the mold or form of pier No. 7. On March 6, 1896, the last batch was hoisted into the form of pier No. 4, and on July 22, 1896, the plastering of all of the piers and abutments was completed.

Molds or Forms.—The forms were all made of 2-in. yellow pine board surfaced on one side, and sized to 1¾ ins. The semicircular ends each tapered at the rate of 1 in. per ft., and were made by first making a double segmental set of ribs, placed 5 ft. apart vertically, and spiking timbers, 2 × 6 ins. (which had been tapered to fit these circles), to the segmental ribs. At each end of these ribs were angle irons bolted to the vertical stanchions, which were 4 × 6 ins., and answered as corner posts of the form.

Between these corner posts there were two additional vertical posts supporting the sides or flat surfaces of the form. They were sheeted up to the inside with yellow pine boards, 2 × 12 ins. These posts were about 4 ft. c. to c. and were held firmly in place by having at intervals of 5 ft. perpendicularly a ¾-in. iron rod, passing through a 1½-in. gas pipe which was fitted inside of the form, the gas pipe acting as a strut, while the rod on the inside was in tension. The construction of the molds is shown in Fig. 6.

These forms were placed in position with the transit instruments, and were watched closely and frequently checked. There being no means to brace the form in the middle of the river except from the interior, it made it a little difficult to keep them in position. This was done, however, by using X-bracing on the interior of the semi-circular ends, and removing it when the concrete would reach the bottom of the braces. After the piers were completed, the gas pipes, of course, remained within the concrete; upon taking the forms apart the rods were easily removed from the interior of the gas pipe.

On the forms of piers Nos. 1, 2, 3, 4, 5 and 6, at the point where the straight barrel of the pier meets the battered line of the upper portion of the structure, there is built with the pier a projecting mold to hide this union as well as to trim and beautify the structure. The form for this molding, Fig. 7, was made by sawing the form blocks with a scroll saw, and fitting cottonwood strips, ½ × 1½ ins., which had been previously soaked in hot water to make them bend readily to the form blocks. This

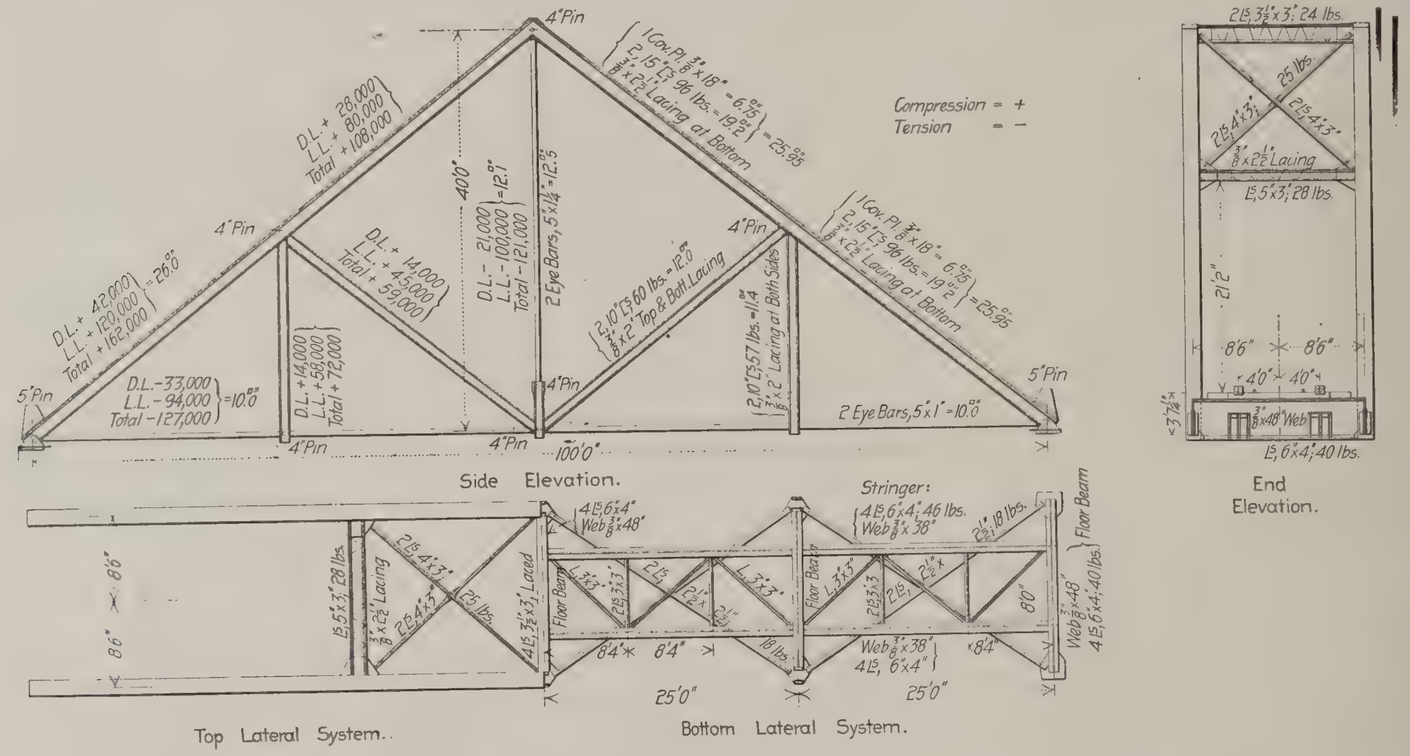

FIG. 1.—WADDELL'S PATENTED "A" TYPE OF THROUGH TRUSS FOR SHORT SPANS.

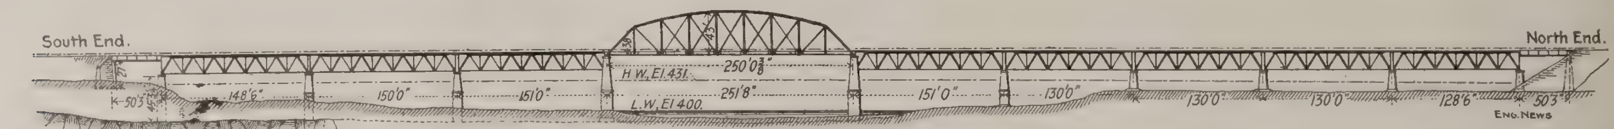

FIG. 4.—ELEVATION OF ARKANSAS RIVER BRIDGE; K. C., P. & G. R. R.

molding was also used on both abutments, and adds very much to the appearance of the structure.

Abutment A.—This is built on sand 7 ft. below the surface of the ground, and is the only one of the structures that is not on solid rock throughout. This abutment, having a broad base and circular wings, was not intended or designed to go down to solid rock, and a year after it was first commenced it had not shown any signs of settling, although it supports an embankment about 30 ft. high, which was placed against this abutment as soon as the form was removed, or within ten days from the time the last concrete was put in the forms.

On Oct. 7, 1895, the base course was put in, which is one foot larger than the neat size of the abutment in all directions. On Oct. 8 and 9, the form for the abutment proper was put in place, and the concreting continued until Oct. 12, when the work was stopped until the foundation of pier No. 1 could be secured, which was then in quicksand. On Nov. 13 work was resumed on the abutment, and it was completed (except the plastering) Nov. 20. The form was removed Nov. 27 to allow the grading contractors to finish up the embankment; and the plastering on the back of the abutment and the portions of the face to be covered with dirt was finished as soon as the form was removed. The balance of the abutment was plastered and finished Dec. 13. All of the coping on the top of the wings is made of concrete and the bridge seat proper is Carthage limestone.

Pier No. 1.—This was the most troublesome of all the piers, notwithstanding the fact that it was built on the bank (practically on dry land). It began to give trouble from the commencement of the work, showing signs of caving and sliding in the excavation. Later on the excavation was carried down to the level of the sand bar, or an elevation of 408, and then a frame 3 ft. larger than the pier was placed in position, and round piles 2 ft. apart were driven to the bed rock on the outside of this crib or frame. The whole excavation was shored to keep from caving, but when the excavation reached the water level, or an elevation of 402, part of the shoring gave way and a number of men narrowly escaped being buried.

The scheme of the contractors was to sheet up the piles on the inside as the excavation progressed. This worked very well until the water was encountered, and then the sand came in so rapidly that it was impossible to use the longitudinal sheeting any further. The contractors then concluded to drive small Wakefield piles and put the frame on the inside. The excavation was carried on in this way, and the piles driven down as the excavation progressed, until quicksand was struck, when another line of small Wakefield piles was driven, and the quicksand excavated by means of shovels until the sand began to cave in around the outside of the crib. This left large crevices, which were filled with hay, sheaf. oats, sorghum stalks, willow boughs, stable manure and other material, in fact anything that would stop leaks. In some cases burlaps and everything available that would stop a crack between the boards was used. The manure and hay eventually worked through the openings between the piles, and very seriously interfered with the pumps in the foundation, many times causing them to be stopped. Eventually the contractors worked the quicksand down within 18 ins. of the bed rock, where they worked day and night for 18 days without lowering the quicksand at all.

A plan was then suggested that finally worked well, and enabled the foundation to be speedily secured. It was as follows: Small cofferdams or minnature forms, 2 × 4 × 2 ft., were made, and placed one at a time along the outside of the neat work, allowing a slight projection of the small form outside of the neat lines of the main forms. These small forms were made with water-tight sides and open top and bottom, so that they could be easily removed after the concrete inside had had sufficient time to set. These forms were placed in the quicksand. 1 ft. apart, allowing the water and quicksand to pass between them in its flow to the pumps, and then the forms were worked down to the bed rock by baling out all of the sand and water from inside them. As fast as one was filled with concrete another would be sunk, baled out and filled, and so on until the circle was completed. When the small forms were all in and filled there was space left between the sides of these small forms and the crib proper for the passage of the sand and water. Next the 1 ft. passageways were to be closed, but it was then apparent that some means must be employed to allow the free flow of water and sand to the pulsometer pumps, which stood in the center of the pier, about 5 ft. from the east end; so for the time being two channels were left, one running north and south and the other east and west, intersecting at the pump. After the form for the pier was in place, it became necessary to put a form around the pump, in order to build up the concrete and leave the pump in a sump or cistern until the pier could be built above the danger line, or the present water mark.

The next step was to confine the water and quicksand to the sump. This was accomplished by putting in a 6-in. wrought iron pipe to connect the outside passageways directly with the pump, and exclude the sand and water from the inside of the form, except that which passed through the pipe. This was done in both channels, and the work of sealing the foundation then commenced.

In the 12-in. spaces left between the small forms, one Wakefield pile was inserted on either side. making a tight joint with the other Wakefield piles that had been driven around the small forms previously, and left there after the completion of this connection. The sand on the bed rock on the interior of these small spaces was then taken out, and the concreting of these openings was then carried out.

All the concrete in this foundation, up to elevation 407, was put in place by means of a chute. The concrete was wheeled in with wheelbarrows into the form, and shot into position to prevent separation of the mixture. The first concrete for this pier was mixed and put in position on Nov. 9, 1895, and the pier was completed on Nov. 23. The form was removed Dec. 2, and the pier was plastered soon after the removel of the form. The coping was set about Dec. 10.

The bank is filled in around the pier as it originally was, and reveted with an 18-in. dry masonry wall, laid with the slope of the bank. which is 1 on 1½. The wall contains 143.7 cu. yds. of masonry, and was let at $2.75 per cu. yd.

Pier No. 2.—This was the easiest and simplest of the piers in the bed of the river. The foundation was secured by driving Wakefield piling around a crib 3 ft. larger than the foundation. This piling is shown in Fig. 8. Some of these piles reached the bed rock, but many of them did not. As the excavation progressed, shores were inserted to protect the sides of the cofferdam. When the excavation reached the lower ends of some of the piles which the contractors failed to get down, then another frame was inserted and another row of small Wakefield piles was driven, and then before bed rock was reached still another row of Wakefield piles was driven.

This proved successful, and concreting was commenced on Oct. 26, 1895, and completed Nov. 3; this pier was partially plastered in December, but owing to the cool weather the plastering was discontinued until May, 1896, when this pier was finished up. It contains 287.88 cu. yds. of concrete; 44.68 cu. yds. of which are below, and 243.2 cu. yds. above an elevation of 400.

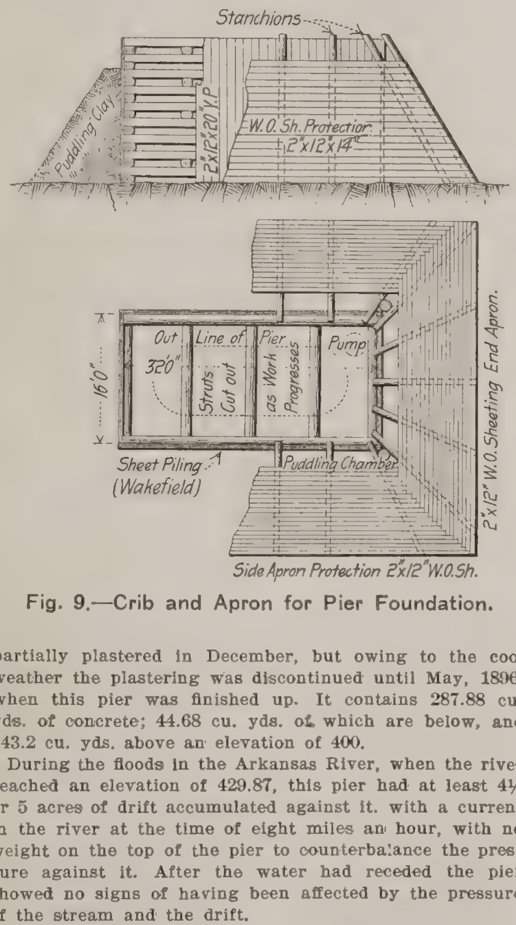

Fig. 9.—Crib and Apron for Pier Foundation.

During the floods in the Arkansas River, when the river reached an elevation of 429.87, this pier had at least 4½ or 5 acres of drift accumulated against it. with a current in the river at the time of eight miles an hour, with no weight on the top of the pier to counterbalance the pressure against it. After the water had receded the pier showed no signs of having been affected by the pressure of the stream and the drift.

Pier No. 3.—This pier was constructed by building a crib of round timbers, flat on the outside and placed in position in about one or two feet of water, and driving Wakefield piles on the outside of the crib, and then placing, by means of a diver, about 1,000 burlaps filled with sand about 10 ft. out from the bottom of the crib. These burlaps were for protecting the crib, and they were hauled in by means of barges. The whole crib was puddled with stiff puddling clay. Numerous small rises in the river from local rains gave considerable trouble, and it was with considerable difficulty that this crib was made to resist the pressure of the water from the outside, and quantities of hay and cane stalks were used to stop the leaks. Finally an auxiliary cofferdam was driven to protect the puddling from the current, after which bed rock was reached. The foundation for the pier was dry, and all dirt and slime was wiped off of the rock bottom with burlaps. There were a few loose flat stones, which were removed with little difficulty.

The character of all the river foundations was a grayish blue sandstone, very hard and rough, and with only an occasional seam. The general surface of the bed rock is quite level.

The pier was commenced by putting the first concrete in position Nov. 18, and was finished Dec. 6, 1895.

The form was removed Dec. 13, and the pier withstsood the floods and drift of Dec. 19 and 20, 1895, during which trees and logs struck the fresh concrete and left no traces of the effects after the flood had receded.

Pier No. 4.—This was the last pier constructed, and many difficulties were encountered during its construction, as the bed rock was scoured by the current of the river and was perfectly bare. A crib was made of round logs, flat on one side with the flat side turned out. This crib was subdivided into four parts or chambers, and loose struts were used to separate the chambers as well as to resist the pressure of the forces from the outside. Wakefield piles were then driven around this crib and sheet piling driven outside of that about 10 ft. away, forming a chamber between the sheet piles and the Wakefield piles, which was filled with puddling clay. The sheet piles were also puddled on the outside, and protected by sand bags. Numerous breaks occurred in this cofferdam, and considerable annoyance was caused by unexpected rises in the river.

Finally, when all was in readiness to begin the concreting, the rains set in and heavy floods occurred all over the country, especially in the valley of the Arkansas and streams tributary to it. They were swollen and overflowed their banks, and the Arkansas River rose rapidly and washed away the cribs, sheet piles, pumps and everything within its banks. All the sand that had been placed on the Cherokee shore, and the broken stone for the whole of pier No. 4, and about one-third of pier No. 5 (about 1,200 cu. yds.), was washed away.

The contractors' pumps, hoisting engines and other machinery, tools, etc., were all left in the bottom of the river. This very naturally affected the progress of the work. This flood occurred Dec. 19, and the water did not recede until after Jan. 21, 1896, when another crib was built similar to the one above described, and the same style of Wakefield piles was used, except that they were longer and the crib was built 4 ft. higher, so that small rises in the river could not affect this foundation work. This crib was protected with aprons built of 2-in. oak planks, set at an angle in all directions, giving chambers between the crib and the aprons an enlarged base. This aperture between the crib and the apron was filled with puddling clay, and a great deal of hay, burlaps and other material was used in connection with the clay to stop leaks in the cofferdam. This construction is shown in Fig. 9. The foundation, on bed rock. was rather smoother than the others, having no loose material on it whatever. The concreting was commenced Feb. 8, and finished March 6, 1896. This pier has an enlarged base, as shown in Fig. 5. It contains 617.76 cu. yds. of concrete, 138.17 of which are below and 479.59 above an elevation of 400. The stone for this pier was all broken by hand, the crusher having been shipped away before the flood.

Pier No. 5.—This is the channel pier on the Cherokee side, and was constructed by using a separate cofferdam made of yellow pine timbers, 2 × 12 ins., 16 ft. long, except the bottom and top fillers, which were 10 × 12 ins., 16 ft. long. The cofferdam was rectangular in shape, 32 × 16 ft., and 18 ft. deep; it was sheeted upon the inside and outside with 2-in. pine boards running longitudinally, and calked with two threads of oakum. The vertical studs. 2 × 12 ins., 18 ft. long, were placed 2 ft. apart. This left chambers or recesses, 12 × 24 ins. between the studs, to be subsequently filled with sand to sink the crib; the recesses being left open at the top for that purpose.

The two parts of the cofferdam joined at each end, the joints being provided with cushions made by tacking canvas facing to the edges loosely, and stuffing them with oakum, making a cushion about a foot thick. The bottom of this cofferdam was built to conform to the contour of the bed rock, which was bare and very rough. At a point 3 ft. above the bottom an additional canvas apron about 12 ft. wide was secured to the sides of the cofferdam by nailing strips 4 ins. wide to prevent the canvas from tearing. This canvas was stretched out horizontatlly and weighted with sand bags, and also with puddling clay.

The contractors abandoned the idea of loading the pockets of the cofferdam with sand, and subsequently loaded the top with burlaps filled with sand, and the canvas apron was loaded with sand bags for 12 or 15 ft. Puddling clay was used, and the whole exterior of the cofferdam was thoroughly puddled. This cofferdam did not prove a success. There was no struts placed inside before the pumps were started, consequently as soon as the water was pumped out the cofferdam sprung in at the center, all along the sides, causing great leaks. The pumps had to be shut down, and divers sent inside to place shores to resist the pressure of the water. Sand bags were also used at the bottom to stop leaks temporarily, as well as keep the lower edges of the cofferdam from further bulging in or slipping. After much time had been lost, the cofferdam was thoroughly braced inside and the foundation for this pier was secured. The bed rock showed a crevice about 2 ft. wide running diagonally across the east end; this was excavated to a depth of 6 ft., when it disappeared. The character of this foundation is bluish gray sandstone, and this crevice seemed to be simply a crease in the solid rock. Concreting was commenced on Dec. 6, 1895, and completed Jan. 31, 1896. On Dec. 18 the pier was built to an elevation of 134.5. The high water then set in, and nothing more was done until Jan. 29. During this flood a portion of the form was torn away by drift wood, but the pier was unhurt. The plastering on this pier was completed July 22, 1896.

Pier No. 6.—This has a foundation above low water mark, but at the time of construction the water was about 2 ft. over the foundation. A half crib was used, a double tarpaulin being fastened to the top of this half crib and extended out in the river about 12 ft. This was puddled with clay and the water kept out. The solid rock sloped at a considerable angle in this foundation, and it had to be blasted to a level. The base of this pier was put in to receive the form on Oct. 28, 1896, when the concreting was commenced. The pier was finished Nov. 5, 1895, and the pier was plastered in June, 1896. In July the river was low enough to permit working around the base, when the Arkansas Conctruction Co. put in 17½ cu. yds. of Portland cement concrete reinforcement around the base, completing the pier, which contains 219.81 cu. yds. of concrete, all above an elevation of 400. This does not include the reinforcement done by the Arkansas Construction Co.

Pier No. 7.—This was the first pier built. It is a shore pier on a solid gray sandstone foundation, only about 18 ins. of excavation through loose rock being necessary to reach the foundation. It was commenced Aug. 23, 1895, and completed Aug. 26, 1895. The pier has a reinforced base, this reinforcement being done by the contractors.

Pier No. 8.—This was the second pier constructed, and the foundation for it is similar to that of No. 7, except that it is deeper to the solid rock. This pier was commenced Aug. 21, and completed Aug. 31, 1895, and contains 111.29 cu. yds. of concrete in the pier proper. It was plastered in December, 1895. The weather turned cold just after this pier was plastered, and a quantity of the plaster was loosened by the action of the frost. In July, 1896, just before the plastering was all completed on the other piers, this pier had all of the loose plaster removed, and was replastered and washed down with a strong solution of cement mortar or liquid cement. The high water of December, 1895, tore up a quantity of loose rock around this pier and exposed the foundation of the east end. In July, 1896, the Arkansas Construction Co. reinforced the base of this pier by putting 24 cu. yds. of concrete around it.

Pier No. 9.—This has the same kind of a foundation as No. 8, except that it is still deeper to the solid rock, and the loose rock through which the excavation is made has a tendency to be more solid, the last 18 ins. of this excavation being through hard, blue slate. This pier contains 107.21 cu. yds. of concrete. The concreting was commenced Aug. 28, and was finished Sept. 26, 1895.

Pier No. 10.—This is built on a hard blue slate foundation, perfectly smooth and solid. The concreting was commenced Sept. 9, and was completed Sept. 24, 1895. This pier has an embankment about it, which is protected by a rip-rap wall above high water mark.

Abutment B.—This abutment, at the north end, is on a hard blue slate foundation, which is level, smooth and solid. The concreting was commenced Aug. 28, and was completed Oct. 28, 1895. This abutment contains 139.94 cu. yds. of concrete and was plastered two coats, floated on with a cork float. The steel float and the third coat were not used except on that portion exposed above the embankment, which is 6 ft. below the top of the abutment. This piece of masonry is covered by an embankment, so that only the top is exposed to view.

STEEL TIES ON THE NETHERLANDS STATE RAILWAYS; 1881 TO 1898.

The use of metal ties was commenced on the Liege & Limburg line of the Netherlands State Railways in 1865, and since 1880 very careful observations have been made of the results obtained with the different types of metal ties which have been in service. This line is on Belgian territory and will soon be transferred to Belgian ownership, under an agreement between the governments of the Netherlands and Belgium, by which each country will purchase those lines within its territory which are now operated as a part of the railway system of the other country. Under these circumstances, the observations as to the metal ties on the Liege & Limburg line will be discontinued, and the Resident Engineer, Mr. Ch. Renson, has therefore prepared a final report on the general results of these observations for the 17 years ending with Jan. 1, 1898. This report will be published in full in the July number of the Bulletin of the International Railway Congress, and we present herewith an abstract containing some very interesting and instructive information. In our issue of April 7 we presented an abstract of a report on the experience with steel ties on the Gothard Railway, of Switzerland, and discussed the relation of the steel tie question to the track of American railways. It is to be noted that on both these foreign lines, where the ties have been used extensively and under proper supervision, very satisfactory results have been obtained both in point of efficiency and economy. The following is the abstract of Mr. Renson's report:

The first trial section of track with steel ties was laid on the Liege & Limburg line in 1865, but in 1880, Mr. J. W. Post, Engineer of Permanent Way of the company, which operates the state railways, was commissioned to study at home and abroad the results obtained from the use of metal ties, and also to inquire into the latest improvements in their manufacture. This investigation resulted in a series of extensive and practical tests, which have been continued in a systematic manner during the past 17 years. The trial sections are 27 in number, and have carried from 100,000 to 150,000 trains.* The present report shows the relative merits of the different systems tried. Up to 1888 ties of types I. to IX., Fig. 1, with fastenings of types A, B and C, Fig. 2, had been put in service. Since then, types X. and XI., with holes drilled instead of punched, and fastenings D, have been introduced, as shown in Figs. 3 and 4. Type O is now obsolete, but most of the ties of this type, which were laid in 1865, are still in use, but their wooden blocks have been replaced by cast-iron blocks. Types I. and II. are of iron, the others are of steel.

FIG. 2.—POST'S IMPROVED STEEL TIES; TYPES X. AND XI.; NETHERLANDS STATE RAILWAYS.

The 27 trial sections of track are on single track, laid with T-rails, the steepest grade being 1.6%, and the sharpest curve 1,148 ft. radius (5°). The traffic carried is from 14 to 25 trains per day, and 29 trains per day over one of the sections. In the accompanying table, the cost of maintenance per mile, and per 10,000 trains, is given for 21 sections, the others not being long enough for statistical purposes. The section No. 1, with oak ties, is a basis of comparison for the ten sections having 25 or 29 trains per day, but not for those with only 14 trains per day, as the relative cost of maintenance is higher, owing to the fact that these expenses are affected by the number of trains as well as by the time the track has been exposed to frost, rain, etc. The figures relating to sections with the lighter traffic are given in parentheses. The expenses are given in labor instead of money, which allows of their being compared with those of railways in countries having a different system of currency.

From my observation of the 27 trial sections during 17 years, and from the statistics of maintenance expenses of 21 of these sections, I present the following results:

The ties with punched holes show, after three or four years' service, little cracks beginning in the corners of the holes (rectangular with rounded corners) and caused by the punching operation, which usually bruises the metal, even in the case of mild steel. These cracks, generally invisible at first, are gradually enlarged by the train traffic. Ties with drilled holes do not crack in this way.

The ties of type I. last longer than oak ties. Calculated at the actual prices, the annual charge for renewal of these ties is only half that of oak ties. The maintenance expenses of tracks with tie I. are higher than those of oak ties; but if the difference is deducted from the difference in annual charge for renewal, there is a surplus of about $43 per mile of track in favor of this tie. It must be observed that type I. is the smallest, lightest and worst of the types tried and is now considered decidedly inferior. The work expended on the inferior systems of fastenings, A and C, had an unfavorable influence on the cost of maintenance of the ties which have these fastenings. For tie I. the maintenance expenses were higher than those for oak ties; for tie II. the difference was less, and so on; each following type being an improvement on the former. For the Post tie of type VI. those expenses are less than for oak ties, and the result is still more favorable for the improved Post types VII. to XI.

The rusting of steel ties is insignificant, even if the roadbed consists of cinders, as is the case on the greater part of this line. Of how little importance the rust is, is clearly shown on another line of the company. In 1865, 10,000 ties of the Cosijns type, Fig. 1 (iron I-beams laid flat and having two oak blocks), were laid between Deventer and Olst. About 200,000 trains have passed over these "venerable" ties, now 33 years old, but they are expected to last much longer, for the oak blocks, which only lasted three to eight years, are now being replaced by iron blocks.

A very important point, which till now has not attracted sufficient attention, is the way in which the tie affects the rail flanges, especially in regard to local wear of rail-flange, tie and fastenings. The rail being much better fastened on the metal ties, the hammering of the rail under traffic (often observed on wooden ties) is avoided. By measuring two series of rails, which had been 14 and 16 years in service, it has been found that on metal ties the local wear of rail, tie and fastenings is insignificant.

When I discovered the little cracks in the metal ties (with punched holes), Mr. Post designed the fastenings of type D (Fig. 4), permitting the use of bolts without a square collar, the head of the bolt being retained between two fillets rolled on the under surface of the tie (Figs. 2 and 4). ---

*Descriptions of the forms of ties experimented with and details of the results obtained with these ties may be found in the following publications:

"Maintenance Expenses of Track on Metal Ties," by J. W. Post, "Transactions of the American Society of Civil Engineers," June, 1888.

"Report on Metal Ties," made by Ch. Bricka to the French Minister of Public Works, 1886.

"Report on Metal Ties," made by J. M. Kowalski to the International Railway Congress, and published in the "Revue Generale des Chemins de Fer," February, 1886.

"Report on Metal Ties," made by E. E. Russell Tratman; Bulletins Nos. 3, 4 and 9 of the Forestry Division, U. S. Department of Agriculture, Washington, D. C., 1889, 1890 and 1894.

round bolts the holes in the tie must be round and can be drilled.

The great difficulty was to induce the steel works to put in the plant necessary for exact, quick and cheap drilling of the four holes per tie. There was some opposition on that point; just as there was at the time when the railway officers wanted to get the holes in steel rails drilled instead of punched. It was only in 1889 that a reasonable contract could be made.

The Post ties X. and XI. (Fig. 2), with fastenings D (Fig. 4), which have been in the track now since 1890, are superior to any of the former types.[†] They not only require very little maintenance work; but whereas types I. to IX. show cracks after three or four years' service, not one of the types X. or XI. (and they have been carefully examined) show a trace of cracks.

*This section is on marshy ground.

†This section has special ties with riveted rail brace and tie-plates, Fig. 5.

Note.—The maintenance figures in parentheses are for track sections having a lighter traffic, and are therefore not directly comparable with those of the other sections. The maintenance work is low on most of these sections, but shows higher figures when divided by the number of trains.

I prefer type X. with "dromedary" waist (Fig. 2), to type XI. with low waist, because with type X. the middle of the tie is not bedded in the lower and firmer part of the ballast, and so the support of the tie is sure to be under and near the rail seats.

A series of these ties, which were examined in 1897, show that the wear of the rail seats of the tie is insignificant and that the wear in the holes also is of no consequence.

For lines with very heavy traffic, however, it may be economical to still further lengthen the life of the tie by applying between the rail base and the tie a mild steel plate, say 10 or 12 mm. thick. In order to examine whether this might cause any reduction in the firmness of the fastening of rail to the tie, I armed some ties of types X. and XI. (fastenings D) with such tie-plates as shown in Fig. 4, and I found that there is no objection to their use, the gage of the track being as constant with these plates as without them.

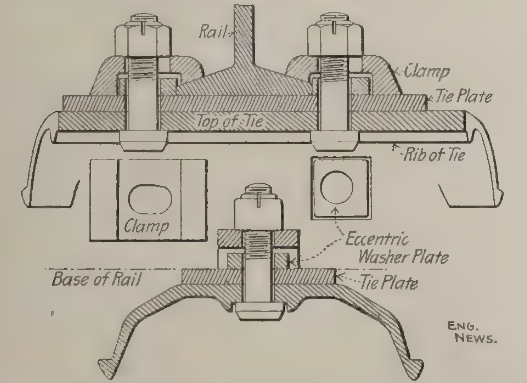

Fig. 4.—Post's Improved Fastening for Steel Ties; Type D. (Showing Tie-Plate.)

These plates can easily be renewed when worn and thus practically lengthen the life of the ties indefinitely, even on lines with heavy traffic.

For very sharp curves in main track, I have tried since January, 1890, a special tie with stamped iron chairs (Fig. 5), which is rather expensive, but gives satisfaction in every respect and is superior to any special system tried on the sharp curves of our lines. Rivets of 30 mm. applied by machine would be preferable to those of 25 mm., as used on the trial track.

As my impressions after these 17 years of experimenting, statistics and observation, I can give the following conclusions:

Grave defects have been discovered, especially the cracks in types I. to IX., and also imperfections in the fastenings A and C. These inconveniences were so important that they would have resulted in abandoning the use of metal ties altogether, had not Mr. Post found the way to avoid them.

The cracks of the ties, which are principally caused by the punching of the holes, are eliminated in the rolled mild steel Post ties, types X. and XI. (Fig. 2), by drilling the holes, strengthening the rail seats and rolling on the under surface two fillets to prevent the bolts from turning. The patent on this has now expired. It is my conviction that the life of these types of ties will be equal to many times the life of oak ties.

The local wear or notching of the rail base by the fastenings, which is sometimes important when spikes or screws are used on wooden ties, is considerably reduced by the use of the eccentric washer plate (Fig. 4), having a large contact surface. Thus not only is the life of the rails lengthened, but the cost of renewal of fastenings has also been reduced to less than that for the renewal of fastenings on oak ties.

If a good design of nut is used (which does not work loose by the vibration), the wear in the holes and on the rail seats of the tie, of the rail base itself and of the fastenings, is insignificiant, and thereby the annual charge for renewal of this track is much less than what it is with wooden ties.

The cost of maintenance, which is somewhat higher with types I. to V. (Fig. 1) than with wooden ties, is decidedly lower with types VI. to IX., and especially with types X. and XI. and fastenings D.

The track gage keeps better on ties X. and XI. with fastenings D than on oak ties and by the solid connection between rail and tie the security is greater. As to resistance to shifting sideways and creeping lengthways by the traffic, these steel ties are far superior to wooden ties.

I would only prefer oak ties in the following limited cases: (1) On badly drained road; (2) On new high and not yet consolidated embankments; (3) On marshy ground; and, (4) With ballast which is but little permeable.

For lines with very heatvy traffic the following improvements might be made:

1. Enlarging the base of ties X. or XI. (Fig. 2) by taking 260 or 270 mm. width (instead of 235 mm.), and 2.7 m. in length (instead of 2.6 m.); this is in order to still further reduce the expenses for packing or tamping.
2. Provide the ties with two tie-plates (Fig. 4) each, in order to still further lengthen their life.
3. Increase the depth of the ends of the tie (Fig. 2) to prevent lateral displacement of the track on sharp curves and in the case of high speed or the lurching of the locomotive.
4. Use bolts 25 mm. thick, instead of 22 mm.

The supplementary expenses caused by these experiments during 17 years are very trifling and the results obtained have proved very useful. The observation of the trial tracks has enabled us to get a definite opinion as to the value of different systems of ties and fastenings. The gradual, but important improvements which we owe to Mr. Post, have contributed to assure the development of metal track all over the world, and also to ensure both greater economy and security.

Finally, I am glad to state that the result of our 17 years' work not only fully confirms the favorable opinion of many engineers, who especially studied the metal track question, particularly Messrs. Ch. Bricka, J. W. Post, A. M. Kowalski, E. E. Russell Tratman, Ch. Lebon and Dietler, but also that our results quite agree with the favorable results on some of these railways,[*] where this question has been examined extensively and with perseverance, by giving different systems a fair and honest trial without preconceived ideas.

[†] The ties with variable section are either rolled in trough shape or they are manufacturd by rolling a flat bar (with variable thickness in some parts, Fig. 2), which is afterwards pressed into trough shape in a matrice. With the same section under the rail base, the economy of material in comparison to constant section is about 15% for the trough shape rolling; it is less with the flat rolling system. It is a long time since these rolling systems were patented; the patents are probably expired and public property now.

[*] See the report of February, 1898, of the Gothard Railway, Switzerland, of which an abstract is to be found in Engineering News of April 17. It is also worthy of notice that the use of steel ties is increasing yearly on the French and German state railways, and that the percentage of steel ties on all railways of the globe taken together is steadily rising.

THE WESTINGHOUSE "ELECTRIC DONKEY" FOR OPERATING TURNTABLES.

In our issue of May 27, 1897, we illustrated a very successful form of electrically operated locomotive turntable which had been put in operation a short time previously at the West Milwaukee shops of the Chicago, Milwaukee & St. Paul Ry. This installation consisted simply of an electric motor and the necessary reduction gearing mounted upon a frame provided with a single traction wheel running on the circular pit rail. Somewhat similar devices have been installed by other railways, the motor in most cases being made in the machine shops of the railway and being more or less crude in design. As these simple means have proved very successful and seem likely to be used more commonly in the future, we illustrate in the accompanying cut a special turntable motor carriage recently put on the market by the Westinghouse Electric & Manufacturing Co., of Pittsburg, Pa., and designed on the same general lines as the one used at the West Milwaukee shops of the C., M. & St. P. Ry. previously described. This motor carriage or "electric donkey," as the builders name it, weighs complete 3,700 lbs. The motor proper is of 10 HP., and the power required to operate the table when loaded with a 100-ton engine is stated to be about ½ HP. per hour.

THE IMPORTS AND EXPORTS OF MANUFACTURES of iron and steel, into and from the United States, have practically reversed value conditions since 1880. From figures lately published by the Treasury Bureau of Statistics, and from a table giving the amounts for each year, we obtain the following comparison for periods of 5 years:

Year.	Imports.	Exports.	Year.	Imports.	Exports.
1880..	$71,266,699	$14,716,524	1896..	$25,338,103	$41,160,877
1885..	33,610,093	16,592,155	1897..	16,094,557	57,497,872
1890..	41,679,501	25,542,208	1898..	12,615,913	70,367,527
1895..	23,048,515	32,000,989			

The list of iron and steel exports is an elaborate one, but some of the most important items for the fiscal year, 1898, are as follows: Bar iron, 12,308,615 lbs.; cut nails, 32,310,393 lbs.; wire nails, 22,894,099 lbs.; locomotives, in value, $3,883,719; wire, 136,951,924 lbs.. Sewing machines, electrical apparatus and supplies and agricultural implements of American make practically go to all parts of the world.

◆

FIGURES SHOWING THE CONDITION of Spain have been compiled by the Philadelphia Commercial Museum. According to this report the population is 18,000,000, of which number 8,726,519, 6,764,406 of whom are women, have no trade or profession. There are 4,033,291 men and 828,531 women engaged in agriculture. School statistics show 1,728,920 pupils with 39,582 teachers, 24,624 of whom are men. There are 97,257 public employees, 64,000 on the pension rolls; 30,477 male and 78 female physicians; 1,151 male and 32 female writers; 3,497 theatrical people; 3,497 male and 319,506 female servants; professional beggars of both sexes number 91,227; priests, 43,238, and nuns, 28,549.

◆

A METRIC CONGRESS of the leading textile maunfacturers of the world will probably be held in Paris in 1900. The congress is called mainly to overcome the difficulties arising from the want of system in numbering the thread used in the textile industry. The U. S. Consul at Liege, Mr. H. W. Gilbert, calls the attention of American manufacturers to this meeting, and says that more business would follow the employment by United States makers of weights and measures to which foreign buyers and consumers were accustomed.

SUBSCRIPTION RATES: United States, Canada and Mexico, One Year, $5.00; 6 months, $2.50; 2 months, $1.00. To all other countries in the Postal Union: Regular Edition, One Year, $7.60 (31 shillings); Thin Paper Edition, One Year, $6.31 (26 shillings). SINGLE COPIES of any number in current year, 15 cents.

Mailing addresses may be changed at will by sending both old and new address. The number on the address label of each paper indicates when subscription expires, the last figure indicating the year and the one or two preceding figures the week of that year; for instance, the number 328 means that subscription is paid to the 32d week (that is the issue of Aug. 11) of the year 1898; the change of these figures is the only receipt sent, unless by special request.

ADVERTISING RATES: 20 cents per line. Want notices, special rates, see page 18. Rates for standing advertisements sent on request. Changes in standing advertisements must be received by Monday afternoon; new advertisements, Tuesday afternoon; transient advertisements by Wednesday noon.

The problem of devising an economical and efficient system of generating and transmitting power for long-distance electric railway operation has become during the last few years one of particular interest to engineers. That there is likely to be a steady growth in railways of this sort there seems every reason to believe, but there is less certainty in the minds of engineers as to the best system for operating them. At present the tendency of practice appears to be to employ some form of polyphase current transmission with direct-current motors for actual car propulsion, the alternating current being transmitted to suitable sub-stations, where it is changed to direct current for supplying the motors by means of rotary converters. It is practically this system which is employed on the Chicago & Milwaukee Electric Ry., which is described elsewhere in this issue, and which is the most recent, and in some respects the most noteworthy, example of long-distance electric railway construction of which we know.

In this railway we have a generating station located approximately at the center of the road, convenient to coal and water, and equipped with modern economical engines directly connected to 5,500-volt three-phase generators. High tension transmission is used to suitably situated sub-stations, where rotary converters change from three-phase to direct current, which by means of feeders and the trolley eventually reaches the car motors. Other combination generators supply either direct current for nearby sections or low-tension alternating current for transformation to high-pressure for transmission. The engines and generators are coupled in such manner as to permit any combination of engines and generators to avoid shut-downs. Storage batteries are used in connection with the direct-current portion of the system to balance the system, equalize the load, etc.

◆

While this train of transformations is successful mechanically and, generally speaking, financially, and has many features which indicate that it may hold its own for some time to come, one is forced to regret that more attention has not been devoted toward developing a practical two or three-phase street railway motor. There seems to be no inherent reason why such motors cannot be made to meet the rigid requirements of power, speed, control and efficiency as well as the present direct-current motor has. The matter of conveying the current to the moving car or train would entail more apparatus, it is true, but, on the other hand, the extreme simplicity and the smaller amount of attention required at the central and sub-stations would seem more than to counterbalance the double trolley necessary. In such a system the current could be generated at any desired voltage up to about 10,000, using stationary armature machines. At the sub-stations static transformers would step this pressure down and feed directly into the trolley circuits, thus eliminating the rotary transformers and the present annoying factors of electrolysis, the effect upon telegraph lines and ground return telephones, etc.

Of course, it can be argued that there is nothing to be gained by the less complicated system, and that the use of the rotary converter and storage batteries, while they increase the amount of apparatus, and cause a loss in transformation, they more than compensate for this by permitting the installation of machinery of smaller output and by insuring better regulation. It is, however, quite possible to use a storage battery plant in connection with a three-phase generating system, if instead of using an ordinary three-phase generator, motor generators are employed, as in the plant already mentioned, in which the dynamos are directly connected to the engines and can run either as direct-current generators, for feeding circuits near the station, or as three-phase generators, for distant circuits. To illustrate the statement just made, suppose such a plant, equipped with an adequate storage battery plant, with the direct-current side connected with the battery plant, and the three-phase side feeding the line during the times when the load was light, as in the early morning, midday or late at night. During these hours of light traffic the engines could be operated at an economical load charging the battery. As the load on the three-phase circuits began to increase, however, the engines could be maintained at this proper load, the battery voltage increased by suitable combining switches, and the direct-current side of the generator used as a motor to help over the "peak." In this way all apparatus could be run at full load, which would thus permit the use of smaller engines and generators, because they would always be working at their most economical point.

◆

Not a little attention has been paid of late in various assemblies of engineers to the standing of engineering as a profession; and it is encouraging to note, despite isolated discouraging instances, that the general public is slowly coming to understand that engineering is a profession, governed by the same rules of honor that govern the legal or medical professions, and its members have a right to similar honorable treatment.

There is, however, much hard work still to be done by the profession in securing the position that it deserves. Perhaps one of the hardest things an engineer who stands up for the honor of the profession has to overcome is the attempt of occasional manufacturing concerns to undermine his employers' confidence in his integrity and impartiality.

An aggravated instance of this sort has just come to our notice, where a manufacturing concern added insult to attempted injury by tendering a bribe to the engineer. Circumstances made this concern especially anxious to sell its goods to this particular customer, as he had already made extensive use of them, but not with perfect satisfaction. This much is said in order to present any extenuating circumstances in the case. The story, as briefly as possible, is as follows: An engineer was called in to make plans for a certain work. He found a patented apparatus in use which had become inadequate for its purpose, through increase in the output of the plant, and the efficiency of which, as compared with other methods, was at least open to question. For a variety of reasons the engineer recommended the adoption of a new system, under which contracts could be let in the open market. The client accepted his recommendation, and work by day's labor was started, although the letting of contracts for the bulk of the work was postponed until warmer weather. About this time, the company whose apparatus was to be displaced went to the client and urged a reconsideration. Later the engineer received a letter from one of the officers of the company in which it was assumed that the engineer's recommendation of the non-patented process was because his services would be more largely required in its installation, and an offer was made of 5 per cent. commission, if he would alter his recommendation and favor the company's apparatus. The offer was, of course, refused.

Next the company began a stubborn fight to discredit the engineer in the eyes of the client, taking the ground that the engineer in advising the adoption of a certain process was a trade competitor, and entitled to no more consideration than themselves. They brought forward the old argument that they could furnish undoubted financial guarantees as to the cost of their plant, which the engineer was, of course, unable to do. They unblushingly admitted their offer of a commission to the engineer, and declared that the offer and acceptace of such commission was a matter of course.

◆

We are exceedingly pleased to state that, notwithstanding all the specious arguments and powerful influences which the company's agents brought to bear, the client was wise enough to perceive their fallacy and to order the work carried out on the engineer's original plans.

We doubt not that not a few of our readers have had similar experiences at one time or another; and have felt the need that in some way the profession should stand together to repel such assaults as this on its integrity and honor.

It is one of the hardest tasks that comes to many an engineer to stand up before a Board of Directors or City Council, to defend his own integrity, and make plain that he stands as their impartial adviser and representative, while the wealthy and influential promoter, the glib-tongued lawyer or the ubiquitous sales agent, who is urging that the engineer's advice be rejected, is merely working for his own profit. Is there any way in which engineers can uphold their professional standard and assist each other to win the day in hard-fought battles of this sort? We know of no way except for each man to stand up manfully and fight his own battles to the best of his ability; and further, to see that so far as possible no professional recognition or distinction shall attach to the man who degrades the honor of the profession by accepting commissions from those whose wares he recommends, or who undertakes to give advice which he is not competent to furnish.

If the engineering profession can do this, honest manufacturers will have no reason, as it must be be confessed they now sometimes have, for offering commissions in order to secure a hearing for their goods or for appealing from an engineer to his principal because their goods have been judged unintelligently or unfairly.

NATIONAL SOCIETIES OF MUNICIPAL OFFICIALS.

The organization of the League of American Municipalities, a year ago, naturally raised the question, is another society for municipal officers needed? The recent meeting of the League at Detroit, reported in our issue of Aug. 11, affords some answer to the question, but does not settle it. Doubtless most of those in attendance at Detroit felt well repaid for going there and for having organized the League, but in the long run would not more have been gained if the members of the new society had joined some of the existing associations, thus strengthening them and widening their field of usefulness? There were already in existence a number of societies, some limited to one branch of municipal activity, and others broader in scope, which would have given warm welcome to all who have united with the League. Whether these other societies would have met all the wants of those who have joined the new one is a fair subject for discussion. The question

UNIVERSITY OF [illegible]

opens a broader field of inquiry and gives occasion to pass in review the causes which led to the formation of the various engineering and other societies open to the municipal officials of the United States and Canada, and to consider the extent to which they are meeting the needs that brought them into existence, or the opportunities that have since arisen. We shall not undertake an elaborate analysis of the subject, our primary object being to examine the claims of some of the newer societies to membership and to indicate how all may be improved in some essential particulars.

When we consider the rapidity of the growth of American cities, the diverse elements of their population, physical conditions and local industries, and perhaps above all the great lack of uniformity of their governmental organization, due to the fact that each state legislature frames city charters not only without regard to other states but in many cases with equal disregard to uniformity within its own limits, it is a wonder that our municipal affairs are not worse than they are. Growth without system and public improvements without knowledge of what has been done elsewhere have been the two great characteristics of American cities. The current of municipal life has been so rapid and our citizens have been so engrossed in their own affairs and in the success of partisan national government that they have been carried along by the stream instead of controlling it. The branches of municipal government that show the greatest number of exceptions to this rule are the very ones that have longest had access to membership in technical societies of national scope, namely, city engineers, water-works superintendents and health officials.

Not so very many years ago the American Society of Civil Engineers was the only national body of men concerning itself with the technical aspects of municipal affairs. That society, ever since it began to be a force in the profession, has given a portion of its attention to water supply, sewerage and paving, but it covers none of these subjects thoroughly and has strangely neglected so important a matter as garbage disposal. Of the many things the city engineer is called upon to deal with, bridge engineering is perhaps the only one whose progress and status is shown by the transactions of the society.

In the earlier days of the American Society of Civil Engineers the consideration it gave to sewerage and paving was more in proportion than now to the development of those branches, for such work was small in amount and done in a haphazard manner, except in some of the larger and more enterprising cities, where it was in the hands of engineers to whom the society was open and capable of meeting most of their wants. With water-works officials the case was different. They were already a large class, with a great variety of perplexing problems to solve and much valuable information to exchange with their fellows, when the society was first coming into prominence. The society met practically none of the wants of the water-works men who were not engineers and only a small part of those who were, largely because those wants were outside the scope of the society. In the early eighties, therefore, the American and the New England Water-Works Associations were formed, and have since grown into two strong bodies, with many members who are engineers, but far more who are not. These associations have the great advantage of being able to give their whole energies to water-works affairs, going into as much detail and personal experience as the members may find profitable. The New England Association holds monthly meetings through the winter and publishes quarterly proceedings of much value, thus taking a high rank among technical societies. The American Association, though holding only one meeting a year, does good work. Taken together, these societies seem to meet all the wants of water-works officials, and if they lack in consideration of questions of pure hydraulics this deficiency is made good by the American Society of Civil Engineers.

Chronologically, there should be mentioned as having been formed about this time the American Public Health Association, a body which has broadened its practical scope and usefulness until it now includes within its membership a few engineers, many health officers, both city and state, and some laymen. The medical profession, naturally enough, has been the dominant element in this association, but such engineering questions as water and sewage purification, street cleaning and garbage disposal figure largely and well in its proceedings. The municipal health officer has for years had his needs well provided for here.

Other phases of municipal affairs provided for by national associations which may be mentioned but need not be discussed, are education, libraries, charities and correction, and quite recently parks and cemeteries. Street railways, gas and electric lighting plants are wholly or largely under private ownership, and have their own national societies, so there are no men devoted to these industries without a society haven.

Gradually, for some years prior to 1894, there was felt to be a need for an organization which would bring together those municipal officials responsible for streets, sewers, and some other public works only lightly touched upon, if at all, by the existing national societies. It seemed especially desirable to reach a class of city officials more uncertain, perhaps, in their tenure of office, than city engineers and water-works superintendents, and therefore all the more in need of the instruction and stimulus of a live national society. As it was realized that many of the individuals joining such a society would soon drop out, it was decided to allow cities to join in their corporate capacity, with the privilege of individual membership for as many officials from each city as might desire it. Along somewhat such lines as these the American Society of Municipal Improvements has developed during the last four years. Some of the officials designed to be reached by this society are more or less closely in touch with several branches of municipal affairs, such as boards of public works, while mayors, councilmen and financial officers are or should be interested in all classes of public improvements and certainly need instruction from some quarter, coming as so many of them do, from business life to municipal affairs and dropping out again before they gain much experience in their new field. With a membership so diverse in its official duties and interests it is not strange that the new society has taken up practically the whole range of public improvements, with some financial and administrative questions in addition.

Within the past few years it has begun to be recognized that the machinery of city government needed attention and that good men were as essential as good methods. Accordingly, good government clubs and municipal reform associations have sprung up all over the country and the National Municipal League has been organized to bind together these clubs and such individuals as desired to further the cause of good city government. This national organization has by no means been confined to municipal officials, but it has afforded an opportunity for the co-operation of all such officials as are interested in its objects.

With all the societies described above it would certainly seem as though no further national organizations of municipal officials were needed. But in the summer of 1897 a call was issued for a convention of mayors and councilmen, which resulted in the formation of the League of American Municipalities. It is hard to say just what causes led to this step. It seems likely that not all the officials responsibble for it were aware of the existence of the various societies already open to them, while others may have felt the need of a comprehensive society, less technical in its character than those named. The attention given by the new society to questions of municipal ownership suggests the idea that there was a desire for a free and extensive interchange of opinion on this subject. Judging from the report of the Detroit meeting of the League (Engineering News, Aug. 11, 1898), mayors predominate among its most active members. The discussion of technical subjects at the Detroit meeting seemed to partake largely of the relation of personal experiences, often limited in time and extent. All this is good so far as it goes, and if combined with more papers and discussions from men who were thorough masters of their subjects it would be all that could be desired. The danger seems to be that, in certain lines, we shall see at these meetings blind leaders of the blind, unless a new element is infused into them.

The League of American Municipalities held its first meeting so closely in advance of the fourth meeting of the American Society for Municipal Improvements as to deprive the latter body of some of its intended speakers. This, coupled with the similarity of the two bodies in scope, has suggested the idea of deliberate rivalry on the part of the new organization. That the two societies appear to be serious rivals there can be no question, but whether this was intended by the new one we cannot say. There are indications that the two societies are drifting into quite different lines, both in membership and methods. When the League was being organized it seemed very doubtful whether it was needed and its future must settle that question. Could the two bodies work together it seems as though material gain would result. The mayors and councilmen would learn from their fellows more actively engaged in the design and construction of engineering works, and the engineers and various commissioners responsible for such works might be benefited from a more intimate association with other classes of city officials, not the least of which benefit would arise from a growing respect for technical men on the part of the other officials. A mere reduction in the number of societies demanding time and money would be an advantage which needs only to be mentioned to be appreciated by many.

Before closing this article it seems desirable to call attention to some of the limitations and possible improvements in the societies passed in review. First of all, it is to be noted that a national society holding only one meeting a year and publishing merely an annual report must of necessity have a somewhat narrow range of usefulness, especially where there are many and rapid changes in membership. More frequent meetings may perhaps be held only with difficulty, or if held can be attended by only a small part of the membership, but they add life to an organization. Committee meetings might be practicable at intervals during the year where larger gatherings are out of the question. The conclusions reached at such meetings, together with other information, might be printed and sent to all members at intervals between the publication of the annual reports.

Many society meetings lose in value because of too crowded programmes. This requires haste in the reading of papers and often limits or entirely cuts off discussion.

The discussions brought out by many papers in the most successful societies, notably in the Institution of Civil Engineers, are of greater value than the papers themselves, and with the papers often form a resume of the whole subject in hand. Most of our societies are lame in this respect. Written discussions should be encouraged, but neither these nor much oral discussion can be expected on papers at all technical in character unless the papers are printed and sent to members in advance of the meetings, a practice that most of the societies reviewed above do not follow.

If discussions are to be of value those participating must be held to the subject by the chairman of the meeting, and in addition the discussions should be edited before publication, making free use of the blue pencil if desirable.

While the officers of any society can do much towards the securing of good papers, these are often largely the result of volunteer efforts on the part of the members, a fact that should be remembered and acted on by all.

In conclusion, we think the limitations and possibilities indicated above show that it is more desirable to strengthen on old society, where possible, than to create a new one. Good work requires good men and plenty of money, and these are best secured by uniting rather than dividing forces.

LETTERS TO THE EDITOR.

Errata in "De Pontibus."

Sir: Permit me through your columns to call the attention of those of your readers who have purchased my "De Pontibus" to a few errors therein. On page 203, 19th line, for "is" write "are." On page 204 the formula should read:

$$P = 550 \frac{HP.}{v}$$

The 550 factor was dropped in typewriting the chapter, which, by the way, was written three times to bring it into its final shape. The other chapters were all rewritten once, and in some cases twice. The first copies of the book that were issued contained also the following typographical errors. On p. 141 the heading should be Chapter XIV., not Chapter XVI., and on p. 157, line 22, last word should read "rever-," the "ver" was left out. These are all the errors thus far discovered, barring blurred letters and omitted hyphens. It was my endeavor to bring out this work without a single error of any kind, but it seems that I was unsuccessful, notwithstanding the combined efforts of my office assistants, several friends and myself. It is by no means an easy matter to produce a book containing some 160,000 words without letting a few errors creep in. It is possible that there are still others than those here indicated. If anyone discovers any, I hope that he will do me the favor to point them out without delay. Very respectfully yours,

J. A. L. Waddell.

Kansas City, Mo., Aug. 13, 1898.

Power of Windmills.

Sir: Mr. Fargusson's suggestion of the formula HP. = .001 D^3 as representing the power of a wind engine in a 16-mile wind seems to fit some of the results found by Mr. Murphy as published in Water Supply Papers, No. 8, but comes far from representing the results found by experiments of Mr. F. H. King, of the University of Wisconsin. Mr. Fargusson considers the Aermotor favorably and gives the formula HP. = .002D + .0001D^3 as his judgment of its power. This would rate a 16-ft. Aermotor at 0.44 HP. Mr. King found it to give 1.08 brake HP., and about 0.25 actual HP. Mr. Murphy's 16-ft. wheel with which I am familiar gave 0.433 HP., which is very close to Mr. Fargusson's formula. The term HP. as applied to a windmill is apt to be very misleading, as its power at any wind velocity is a function of its load as well as of the wind energy at its disposal. This is clearly shown by comparing the two results cited. Since during only about 4% of the year is the wind at 16 miles per hour, and only about 10% even in the immediate neighborhood of that rate, the usefulness of a windmill rating based on a single wind velocity and unknown load is doubtful. For instance, knowing that a mill actually gives 0.5 HP. in a 16-mile wind, could one predict what would be the output in any season? I think not. This is usually desirable to know, and only by knowing the wind distribution can it be discovered. The following figures which I am using are based upon records kept for seven years, and represent mean values for a well loaded mill reaching its maximum efficiency in a 16 to 20-mile wind:

Table Showing Millions of Foot Pounds of Output per Square Foot of Sail Area in Each Month; Distribution Based on Kansas Wind Records:

January	1.38	July	1.17
February	1.6	August	.8
March	2.58	September	1.59
April	2.49	October	1.6
May	2.07	November	1.9
June	1.58	December	1.67

The figures represent millions of foot pounds of work in lifting water, done by each square foot of sail area exposed by the mill. The figures include the effect of winds between 6 and 30 miles per hour. They also include the varying efficiency of a typical mill between these extremes of velocity and distribution. They cannot take into account the very important factor of relative load on the mill, but they do take into consideration the wind distribution and the variations in efficiency of a typical plant at the various speeds. To estimate the probable amount of water pumped by a 10-ft. mill, say in July and August, add the figures from the table for those months 1.17 + 0.8 = 1.97, representing 1,970,000 ft. lbs. of useful work for each square foot of sail area. A 10-ft. wheel has about 55 sq. ft. of sail area, giving a total for the two months of about 100,000,000 foot pounds of useful work. From this the quantity from any depth of well can be readily found. I know of no other figures or formulas which will give this kind of information. From the nature of the problem such estimates cannot be very accurate, yet, using these figures which do not include Mr. King's work in any way, they check with his work so closely as to be remarkable. They also check with some of Mr. Murphy's results as far as the data is discoverable. Mr. King's 16-ft. windmill and pumps actually did 2,679,000 foot pounds of useful work in the year. The sail area was about 135 sq. ft. Using the figures as I have deduced them would have predicted a yearly output of 2,700,000 foot pounds.

Very respectfully,

O. P. Hood.

Houghton, Mich., Aug. 13, 1898.

BREAKWATER CONSTRUCTION ON THE AMERICAN COAST.*

In this paper reference will be confined to that class of breakwater construction which belongs to the ocean coast of our country, thereby omitting any detailed allusion to breakwater construction upon the great lakes, where the conditions surrounding the problem are so widely different from those belonging to the ocean coast, that but little correlation exists between them.

Without a definition there might be some misunderstanding as to the class of constructions to which reference will be made, since we find that the terms breakwaters, jetties and piers are sometimes confusingly used. A breakwater is an artificial structure, providing a harbor or roadstead with protection against waves, and differs from the other constructions named, in that it is essentially a wave-breaker.

Breakwaters, through their object, may be divided into two classes, viz., those which give shelter and protection to commercial harbors or their entrances; and those sheltering an anchorage or roadstead: the latter are denominated harbors of refuge, and are only used by vessels in transit, which have occasion to escape from the violence of passing storms. Each of these classes might be technically further divided according to their particular type of construction; which in turn is decided by the question of initial or ultimate economy, with due regard to effectiveness. For example, where durable rubble stone could be cheaply obtained the breakwater would probably consist of random stone, of suitable sizes, deposited in the form of an embankment, or mound. Where such stone could only be obtained at considerable cost, concrete blocks might be substituted, and either deposited as the random stone would be, or in the form of a massive and regular wall; or the stone might be used for a substructure surmounted by the concrete blocks as a superstructure. The latter form has been extensively used abroad; but has never been adopted, though frequently considered, upon the ocean coast of our country.

An abundance of durable stone, convenient to the coast, is to be found along that part of the Atlantic north of Cape Hatteras, and along the Pacific coast. This fact, supplemented by the modern methods of cheap quarrying and handling of stone, has made its use much more economical than that of concrete blocks, and has thereby decided, in this country at least, the question in favor of random stone for breakwater construction along our ocean coast.

The limits of this paper will not permit more than a passing reference to the forces impressed upon breakwaters through wave action; but brief allusion thereto becomes necessary, since the amount and direction of these forces must be carefully considered before the proper design and position of the breakwater can be adopted, or the general principles of breakwater construction understood. In the problems of the engineer, the maximum force likely to be impressed upon the structure determines the necessary stability to be given the construction. While it is difficult to estimate, except approximately, the force or impact of breaking waves, observation and experience furnish some data for deductions. The English engineer, Thomas Stevenson. followed by others, has furnished the results of experiments, through the aid of marine dynamometers, which assign values to the wave forces to be met and resisted. These observations recorded pressures in the North Atlantic of 6,000 lbs. per sq. ft.; and in the German Ocean of 3,000 lbs. M. Le Ferme, from the destruction of the beacon at the mouth of the Loire, calculated that the wave forces impressed upon the work must have exceeded 4,800 lbs., and probably approximated 6,000 lbs. per sq. ft. The most remarkable observed instance of the power of waves was afforded by the movement of a solid mass of masonry, set in cement in the form of a massive block, weighing 1,350 tons, at the end of the Wick-Bay breakwater. The mass, 45 ft. wide, 26 ft. long and 21 ft. high, was completely turned around upon its base, and at last tilted off its foundation.* Extraordinary as this may appear, it was subsequently surpassed when another concrete block, substituted for the one just described, was in like manner carried away, though it contained 1,500 cu. yds. of concrete masonry, and weighed about 2,600 tons.

In 1884, Mr. William P. Judson, C. E., made some observations upon Lake Ontario at Oswego, N. Y., to determine the height, velocity and impact of the waves upon the breakwater at that locality, with the following results: During a severe northwest gale, the waves at a distance of 1,000 ft. outside the breakwater, attained a height of from 14 to 18 ft. above the normal surface of the lake, with a velocity of from 30 to 40 miles per hour. Dynamometers attached to the face of the breakwater at depths of 8 ft. below the surface, at the surface, and 8 ft. above the surface, recorded pressures, respectively, of less than 10 lbs., 600 lbs., and at the higher elevation about 1,000 lbs. per sq. ft. The instances referred to are the maximum forces which have been observed, but, since they depend upon local conditions, cannot be assumed as those which are to be the standard in all cases. The height and force of impinging waves at any locality depend upon the force and duration of winds, the depth of the water, the fetch or distance over which the waves move, and the angle of incidence at which they strike the breakwater.

Theoretical conditions indicate that the energy of the impact of waves varies as the cube of the waves' height. Stevenson, from observation, developed the empirical formula, $h = 1.5 \sqrt{d}$, for the determination of wave-heights, which is considered as representing with tolerable accuracy the heights of waves during heavy gales, in which h is height in feet, and d the fetch of the waves in miles.* The results of this formula for low values of d are somewhat too small, while for large values of d they are too great. Scott Russell considers that 27 ft. is the greatest height of waves in the British seas; and Sir G. Airy, from theoretical consideration, concludes that from 30 to 40 ft. would be the extreme height of unbroken waves, except under rare conditions. Dr. Scoresby observed waves in the mid-Atlantic which averaged 26 ft. in height, and moving with a velocity of over 30 miles per hour, while the highest wave he estimated to have a height of 43 ft. Waves have been observed off Cape Horn with a height of about 50 ft. Previous to the laying of the first Atlantic cable, an effort was made to carefully collate the most reliable information upon this point; the result was that 50 ft. was considered as the extreme height of waves in the open sea.

On the assumption that, at the instant of breaking, the vertical section of a wave at the surface is a common cycloid, and that the height, d, of the wave is not greater that the depth of water in which it moves, theoretical considerations indicate that the maximum wave energy, in foot-pounds per lineal foot of the wave crest, =

$$\frac{64 \pi d^3}{32} = 2 \pi d^3;$$

the weight of a cubic foot of sea water being taken at 64 lbs.† for wave-depths of 10 ft., this gives an energy of 6,300 foot-pounds, and, for wave-depths of 15 ft., about 21,000 foot-pounds. If the form of the wave at the moment of breaking is that of a prolate cycloid, as some authorities assert, its energy would be about 60% greater than that above stated. While such calculations are more curious than valuable, they nevertheless serve to convey some idea of the forces impressed upon breakwaters by wave-action.

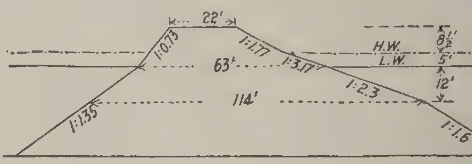

Fig. 1.—Section of Old Delaware Breakwater.

The destructive effect of waves of translation also depends greatly upon the angle of incidence between their line of impact and the axis of the breakwater, and, other conditions being equal, this force of impact will vary with the sine-square of the angle of incidence. At Wick it was found that by changing the direction of the axis of a part of the work, so as to reduce this angle from 90° to about 80°, the breakwater withstood the action of waves, which previously had been such as to repeatedly destroy the work.

From this brief consideration of the wave-forces impressed upon a breakwater, it is evident that its design, from the standpoint of stability, must depend upon conditions arising from the location of the work. In the case of random-stone breakwaters, this question of stability depends upon the cross-section of the work, and the dimension of the stone used upon the active slopes. Such a breakwater essentially consists of two parts, viz., the substructure or that part below the surface of the water, and the superstructure or that above water. The wave-action which it is necessary to arrest by a breakwater does not extend to a great depth below the surface of the water; therefore, the superstructure and the upper part of the substructure are the effective parts of the breakwater, as well as the parts of the construction which are subjected to the most destructive action of the waves. A large part of the substructure, therefore, becomes simply a means of supporting the superstructure, and the limited part of the substructure which is exposed to marked wave-action. In general terms, the necessary dimensions of the superstructure and the upper part of the substructure, determine the dimensions of the remainder of the work. While the superstructure must resist severe wave-action, it must likewise preserve the needed tranquility of the areas behind it, by being carried to a height sufficient to prevent waves being thrown unduly over the top of the structure.

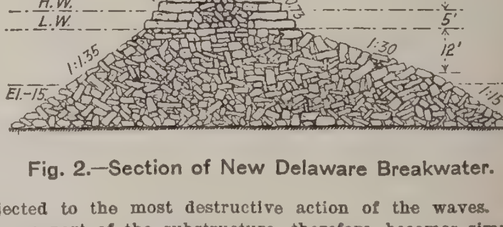

Fig. 2.—Section of New Delaware Breakwater.

The bounding surfaces of a random-stone breakwater consist approximately of plane surfaces, forming the top, bottom and sides: the latter, at more or less of an inclination dependent upon the special part of the work to which they belong, are called the slopes. One side of the work is exposed to the action of the sea, while the opposite side rests in the comparatively quiet water of the protected area. The sea face of the work, while receiving and arresting the energy of the waves thrown upon it, is not, from the limited depth of wave-action, exposed throughout all of its depth to the same amount of destructive force; therefore that side of the breakwater need not be provided, for its entire depth, with the same measure of stability.

†"Report, Chief of Engineers, 1889," p. 1321.

Experience upon American breakwaters has determined that the depth to which energetic wave-action extends is about 12 or 15 ft. below the surface of water; and this depth is generally assumed, upon our works, as the approximate plane of rest for the material which is used.

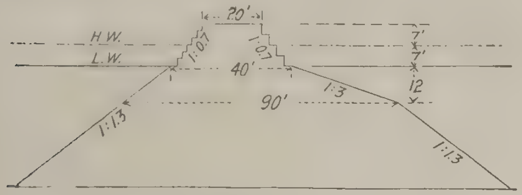

Fig. 3.—Section of Proposed Breakwater, San Pedro, Cal.

Since our breakwaters are all placed in tidal waters the position of this plane must vary with the amplitude of the tide, which in the breakwater locations to be referred to is between 3 and 8 ft. Upon leading European breakwaters, of nearly the same type as those under consideration, the increased exposure of their sites, and the height of ocean waves impressed upon the works, lowers the plane of rest to a depth of about 20 ft. below the surface of the water; while the tidal range of their localities is nearly double that above given for American breakwaters. It is evident that these facts must materially change the details of American and European practice.

In a qualified sense, the so-called plane of rest is more of an abstraction than a well-observed and established fact, and it should not be inferred, from the use which is made of this term, that a clearly defined depth-limit to the disturbing effect of wave-action can be undeniably assumed, within the limits usually ascribed to this plane. It is true that a point must exist in a wave's depth where the impulsive force is a maximum, and it is equally true that upwards and downwards from this point the force must decrease; but the law of this decrease does not permit the conclusion that wave-action entirely ceases at the depths assigned to the plane of rest in breakwater construction. It simply means that at the assumed depths the disturbing effect of the waves has been so reduced that it is no longer able to move the special stones constituting the slopes at such depths. If these stones were larger the plane of rest would be raised, and conversely, if they were smaller it would be lowered.

From the foregoing consideration the slopes of a random stone breakwater may be divided, from the forces impressed upon them, into the following: (1) that part of the sea face which is below the plane of rest; (2) that part which is between the plane of rest and the surface of the water; and (3) the part above the surface of the water. On the harbor side but two divisions of the slope need consideration, viz., that below and that above the water surface. Upon the sea face below the plane of rest the random stone will assume a slope coincident with the angle of repose of the material, unaffected by wave-action; on that part between the plane of rest and the surface of the water, the slope will be formed by wave-action, modified somewhat by the dimensions of the stone constituting the slope; while above the surface of the water, both on the sea and harbor faces of the work, the slopes will be artificial, and dependent upon the size of the stone and the care with which they are laid. On the harbor face, where the structure is not exposed to wave-action, the slope from the surface of the water to the bottom will be that of the angle of repose of the material. These several slopes, as determined by experience and practice, will be considered later.

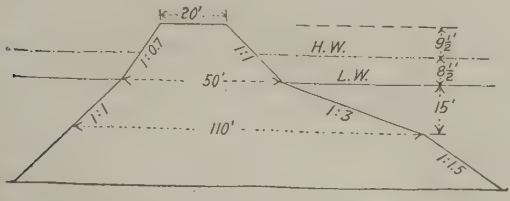

Fig. 4.—Section of Sandy Bay Breakwater.

Where the wave impinges upon a nearly vertical surface, the wave is thrown to a considerable height, and in falling is reflected, in part, seaward; while experience indicates that a talus causes the wave to break and thereby dissipate its energy upon the sloping surface on which it impinges; this is said to be fully realized when such a slope is about 1 on 3. Upon the vertical face type of breakwaters waves have been observed as thrown to a height of 200 ft.; this fact serves to strikingly illustrate the energy contained in waves, and the stresses brought upon the construction in the arrest of wave-force. Upon any slope less than the angle of repose of the material, the size of the stone determines largely the stabliity of the slope to resist forces tending to disturb its equilibrium. In general terms such stability increases with the dimensions of the stone used; and, within proper limits, the active slopes of the breakwater must be increased—with a proportional reduction of the aggregate volumes of material used in the work and a consequent reduction in cost—by the use of larger individual masses of stone in these slopes. The limit of such economy is reached, however, when the increased cost of larger stone equals the saving in the cost of the aggregate volume of stone used in the work. This has led in European practice to the use of immense blocks of concrete upon the most exposed part of the sea slopes of random-stone breakwaters.

The dimensions of the stone used in the active slopes of the substructure usually vary between 2 and 5 tons, with smaller stone constituting the interior volume of the work. Since the superstructure is above the surface of the water it permits of the cheap application of labor to the orderly arrangement of the stone constituting its mass, whereby a saving in volume, and consequent cost, is obtained by using very large stones, laid with some approximation into the form of a rough, though strong and heavy wall. Upon this part of the work stones weighing from 3 to 10 tons each are used on the sea and harbor faces, with a core of somewhat smaller stones.

Under American experience and practice the general slopes of the several parts of the sea and harbor faces are as follows:

Sea face, below the depth of 12 to 15 ft.	1 on 1 to 1 on 1.5
From 12 to 15 ft. depth to low water.	1 on 3
Low water to top of superstructure.	1 on 0.7 to 1 on 1
Harbor face, from bottom to low water.	1 on 1 to 1 on 1.3
Low water to top of superstructure.	1 on 0.7 to 1 on 1

The superstructure usually has a width on top of about 20 ft., and with the slopes above given the dimensions of the resulting sross-section of the entire structure become dependent upon the height of the superstructure and the depth of water in which the breakwater is placed. Upon the two most recent works, viz., the breakwater for the National Harbor of Refuge in Delaware Bay, which is now in progress, and the proposed breakwater for the Harbor of Refuge on the coast of Southern California, at San Pedro, the top of the superstructure is placed at a height of 14 ft. above the plane of low water. With these dimensions for the superstructure and the slopes above given, the breakwaters at the localities named obtain a width of about 40 ft. at the plane of mean low water, and about 90 ft. at the assumed plane of rest, 12 ft. below the plane of low water.

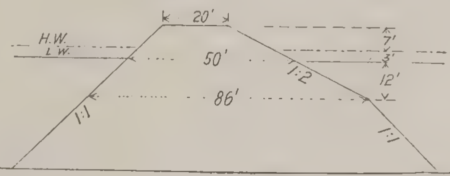

Fig. 5.—Section of Point Judith Breakwater.

The most typical random-stone breakwaters of the ocean coast are at Sandy Bay, Cape Ann, Mass.; Point Judith, R. I., and Delaware Bay, Del. A second breakwater is in progress of construction in Delaware Bay; while the report of a recent Board of Engineers decides upon San Pedro Bay, California, as the proper site for a breakwater to give protection to deep-water commerce, and furnish a harbor of refuge for the South California coast. The Delaware breakwater had its inception in a plan submitted in 1828 by a board of commissioners appointed by Congress. The project proposed the construction of two massive works, on the peirres perdue or rip-rap system, separated by an interval of 1,390 ft.; the larger work, called the breakwater, to afford safe anchorage during gales from the north and east; and the lesser, called the ice-breaker, to protect shipping against northeast gales and the heavy drifting ice of the bay. These works were commenced in 1828, continued under regular appropriations until 1840; resumed after the war in 1866, and completed in 1869. The aggregate amount expended was $2,192,103, which resulted in the construction of 2,558 ft. of breakwater, and 1,359 ft. of ice-breaker. In 1882 a project was adopted for closing the gap between the two detached works; and in 1883 work was commenced thereon. At the present time this work is in progress, and will probably be completed at an early date, whereby the entire construction will attain a length of sligthly more than one mile. The cost of the entire work will be about $3,000,000.

By combining a large number of sections of the Delaware breakwater, as determined by careful survey, the present slopes of the work may be classified as follows:

Plane of rest—sea face—at depth of 12 ft. below low water:

Sea face slope, below plane of rest.	1 on 1.6
Between plane of rest and low water.	1 on 2.9
Between low and high water.	1 on 3.17
Between low water and top of superstructure.	1 on 1.77
Harbor face slope, between bottom and low water.	1 on 1.35
Between low water and top of superstructure.	1 on 0.73

It should be noted that the slopes directly above and below low water line on the sea face of the work vary but slightly from each other; the lower slope being 1 on 2.9 and the upper 1 on 3.17, or respectively about 19° and 17½°. This slight difference of about 1½° is probably within the error of determination, and without serious error the entire slope between the plane of rest and the base of the superstructure can be taken as about 1 on 3. The assumption that the plane of rest occurs at 12 ft. below low water is simply derived from the evidence of these slopes. These slopes are graphically shown on the section below.

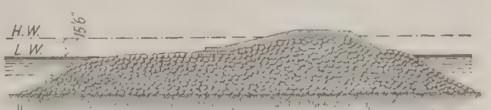

Fig. 6.—Section of Breakwater at Plymouth, England.

The mean cross-section of the first Delaware breakwater has the following dimensions:

Width at top of superstructure	22 ft. 0 ins
Height of superstructure above high water	8 " 6 "
Difference between high and low water	5 " 0 "
Width at high water	43 " 0 "
" " low "	62 " 9 "
" " plane of rest	113 " 9 "
" " bottom	166 " 0 "
Total mean height	43 " 6 "
Mean cross-section, in square ft.	4,100 "

The ice-breaker, which from its position is much less exposed to the action of the waves, has a slope upon the sea face of 1 on 2, and on the harbor face of about 1 on 1.3; the mean cross-section of the ice-breaker is about 3,600 sq. ft. The calculated volume of the breakwater and ice-breaker, including voids, as determined from surveys, was 595,000 cu. yds. The quantity of stone delivered in the works was 892,528 gross tons. These figures would seem to indicate that 1.5 gross tons were required for each cubic yard of volume of the breakwater.

The foundation of the works must have sunk somewhat into the bed of the harbor. through the weight of the mass; recognized scour at the ends of the structure caused considerable material to fall into these holes; while other material has probably been carried by the sea outside of the limits of the work. These volumes have been omitted by the survey, and consequently have given too small a mass for the material deposited in the work. A survey of the material deposited in the gap between the breakwater and ice-breaker gave 1.17 gross tons per cubic yards of enrockment; while the careful measurement of a large volume of stone weighed onto barges gave 1.15 gross tons per cubic yard of volume. Observation derived from rock in settled railroad embankments give about 1.18 gross tons per cubic yard of space occupied. From these considerations Major Raymond derives the conclusion that 1.25 gross tons per cubic yard of random-stone embankment is an ample allowance for each cubic yard of breakwater after the settlement of the mass, and any loss of stone which may occur.* The stone which has been used in the Delaware breakwater weighs from 160 to 170 lbs. per cu. ft.

The Delaware breakwater has been the prototype for all other acomplished or proposed random-stone breakwater construction upon our ocean coast; and while its details have not been exactly repeated, the experience gained upon the work has been utilized both in design and construction at all other localities. The early records of this work seem to indicate that the Board of Commissioners, who designed the breakwater in 1828, were materially influenced by the dimensiens and slopes used upon European breakwaters at that date, and that its foundation width was based upon anticipated slopes such as would be derived from the examples then before them; therefore, it cannot be correctly assumed that the cross-section of the Delaware breakwater of to-day is exactly the result of slopes derived from the action of the wave forces which have been impressed upon them. The history of the work indicates that, at some time after its commencement, those in charge probably abandoned the idea of following the early adopted cross-section, and in place thereof sought to obtain such slopes as would result directly from the action of the waves; therefore, it follows that probably the resulting cross-section of the work of to-day is a compromise between anticipated and realized slopes upon the several parts of the structure.

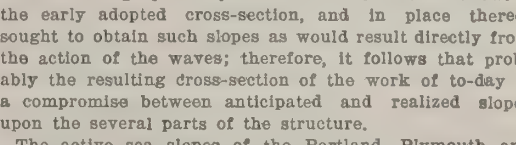

Fig. 7.—Section of Breakwater at Holyhead, Wales.

The active sea slopes of the Portland, Plymouth and

---

*Report of Chief Engineers, 1891, page 1081.

Cherbourg breakwaters vary from 1 on 4 to about 1 on 8; while, as previously noted, the flattest slopes of the Delaware breakwater are about 1 on 3. In this respect it presents a striking contrast to European breakwaters in the steepness of its active sea slopes. While the Delaware breakwater is not exposed to the force of seas such as are thrown upon the European works named, it is highly probable that its slopes, through the method by which they have been obtained, are more nearly in equilibrium with the forces which are impressed upon them than obtains in the European cases referred to.

It is evident that the maximum economy in random-stone breakwater construction is realized when the slopes and consequent cross-section are such as to place the work in simple stable equilibrium with the forces which it is to resist. Any additional material beyond this would be unnecessary, and, therefore, an extravagance. To secure a stable section, and at the same time provide that it shall contain the minimum volume of material, requires that its method of construction should be carried on in the three following stages: (1) The formation of the volume below the plane of rest; (2) the deposition of the volume between the plane of rest and the base of the superstructure; (3) the construction of the superstructure. This order of construction has been developed and carried into practice by Major C. W. Raymond, Corps of Engineers, U. S. Army, who has present charge of the completion of the Delaware breakwater, and also the construction of the new breakwater in Delaware Bay. Major Raymond's extended experience in breakwater construction on the ocean coasts of the United States placed him upon the Board of Engineers for the location and plans for a harbor of refuge upon the coast of Southern California; and upon his plans and specifications the several reports upon this important work have been mainly based.

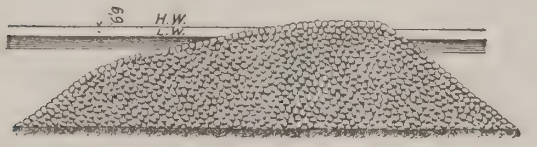

Fig. 8.—Section of Breakwater at Portland, England.

Under the order of construction above indicated the deposition of the random-stone is confined strictly to a width and depth conforming to the width and depth of the cross-section of the breakwater at the assumed plane of rest; by this method the material on the slopes is forced to assume the steeper angles of repose which properly adhere to this part of the work; at the same time the initial settlement of the foundation and this part of the mass is secured. When this lower section of the breakwater is completed it is followed by the second stage, the formation of the mass between the plane of rest and the base of the superstructure, by the deposition of all material within the width of the base of the superstructure; care being taken in this important section to deposit the larger stone upon the sea side of the breakwater. This brings the construction within the disturbing action of the waves; and as this part of the work progresses the stones upon the sea face of the work assume such slopes as to place the work in actual equilibrium with the wave forces impressed upon it; thereby leaving to the sea the task of largely declaring the slope and consequent stability which is required to meet the peculiar conditions of the exposure. If the engineer, for any reason, has erred in judgment by assuming too steep slopes, the action of the sea revises his calculations, and, beyond the possibility of mistake, corrects the error. It is evident that by this method the minimum volume of section, and consequent maximum economy of cost, consistent with required stability is obtained.

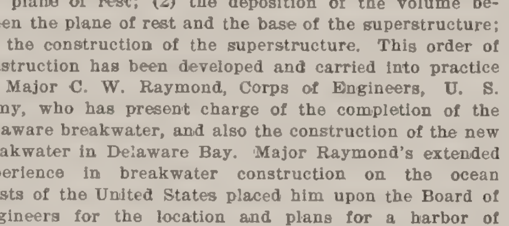

Fig. 9.—Section of Breakwater at Cherbourg, France.

By the time the entire breakwater has been completed to the height of the base of the superstructure an opportunity has been given this part of the work to thoroughly settle, so as to be in condition to receive the construction of the superstructure, which is not undertaken until a condition of stable equilibrium has been attained by the substructure, and its upper surface carefully levelled to receive the superimposed mass.

The superstructure, in the most recent types of American random-stone breakwaters, consists of rough, strong walls upon the sea and harbor faces of the work, built of larger stone systematically placed, so as to secure a strong bond; the space between these walls being filled with stone varying in size so as to form a compact mass without large interstices. This part of the work requires the use of powerful derricks for handling and properly placing the large stone constituting its mass. Under the methods above outlined, the several widths of deposits for the random-stone are marked by carefully placed ranges, and within their limits all material is strictly deposited. In this respect the practice now varies greatly from that of former times, when wide latitude was given to the areas upon which the stone was initially deposited in the efforts, then in vogue, to form predetermined slopes through the deposit of stone directly upon such slopes. Until later times it has been the practice to transport the stone to the site of the work upon sailing vessels, deck-scows, barges or other available means of water transportation; this necessarily resulted in more or less of a haphazard method of discharge and deposit, arising from the fact that the vesels used were not fitted with machinery and appliances for quickly and accurately placing the stone in the work. Such methods unquestionably resulted in considerable waste of material through its not being deposited exactly upon intended areas.

Under the methods now in operation upon the new breakwater for a National Harbor of Refuge in Delaware Bay, the material below the assumed plane of rest, as well as a part above this plane, is transported to the work in dump scows of 1,400 tons capacity, and specially arranged construction, whereby the entire load of such scows is released at once, and, without the intervention of labor or machinery, deposited, en masse, through the bottom of the scows directly upon the width of section on which the material is desired. Besides ensuring accuracy of deposit, the abolishment of the former large element of hand labor in the discharge of stone, permits the unloading of these scows during a rough condition of the sea, when, under past methods, it would have been either impracticable or, if attempted, resulting in an uncertain and unsatisfactory deposit of the material upon areas probably somewhat removed from those on which the stone should have been deposited. The remainder of the plant for the delivery of the stone in the new breakwater consists of large seaworthy barges, of 1,500 tons capacity each, provided with powerful steam derricks, capable of handling 15 tons, for quickly and certainly placing the stone at desired points.

The breakwater for the National Harbor of Refuge in Delaware Bay, which is now in progress, a section of which is shown here, is located outside of and nearly 2½ miles north from the existing breakwater. It is placed in water from 13 to 53 ft. deep, has a length of about 1½ miles, and covers a protected anchorage against the heaviest storms of 552 acres, with a minimum depth of 30 ft., and an additional area of 237 acres, with a minimum depth of 24 ft. These combined areas would give free and good anchorage to more than 1,000 vessels. The work is estimated to contain 1,384,000 net tons of stone, and will cost, with the projected ice piers, probably about $2,500,000. Although only commenced during the present season, the specifications for the work require its completion by December 31, 1901, through the annual deposit of about 280,000 tons of stone. Since the prevalence of severe or stormy weather practically reduces the working season available for depositing material in this breakwater to about seven months for each year, it follows that an average output of 40,000 tons per month must be provided for by the contractor. The work is being executed at this rate, which is far beyond anything ever before attained in earlier breakwater construction. The average price paid for stone in the old Delaware breakwater was about $2.50 per gross ton. Under the existing contract for the construction of the new breakwater, which covers the entire completion of the work, the price is $1.18⅜ per net ton.

The proposed breakwater for the projected deep water harbor at San Pedro, California, a section of which is also shown here, is located in water from 19 to 51 ft. deep. It has a projected length of 8,500 ft., and covers an anchorage area of 615 acres, with depths varying between 24 and 36 ft. The work is estimated to contain 1,782,000 cu. yds. of stone, or 2,290,000 gross tons. The material in the superstructure below the plane of rest is estimated at $1.25 per cubic yard; that above the plane of rest at $1.50 per cubic yard, and the stone in the superstructure at $3.00 per cubic yard. The entire estimated cost of the work, including contingencies, is $2,901,000.

The National Harbor of Refuge at Sandy Bay, Mass., was commenced in 1885, and is still in progress. It has a projected length of 9,000 ft., and covers an anchorage area of 1,377 acres, carrying a mean low water depth of 24 ft. and over. The material below the plane of rest. which in this case has been assumed at 15 ft. below water surface, consists of stones not exceeding 4 tons in weight; while the portion above low water requires stone not less than 4 tons and averaging 6 tons in weight. The contract prices paid for the stone already deposited in the work have been from 60 to 75 cents per net ton. The larger stones comprising the superstructure will greatly exceed the foregoing prices: the proximity to the work of large granite quarries has permitted the exceptionally low prices paid for the stone. The estimated cost of the entire project is $5,000,000.

The breakwater at Point Judith, R. I., was commenced in 1890, and is still in progress. It has a proposed length of about 10,000 ft., including an auxiliary breakwater protecting one of the entrances to the harbor. The protected area, carrying 18 ft. depth and over, is about one square mile. The work is built in water from 18 to 30 ft. deep, and its estimated cost is $1,250,000. In 1893 the government contracted for the entire completion of the work at the rate of $1.28 per net ton for all stone required.

By way of comparison the following sections of European breakwaters illustrate the difference between American and European practice in the construction of random-stone breakwaters, as well as the marked variation in the active slopes of such works. It should not be too strongly assumed that slope variations are due in all cases to corresponding differences in the forces impressed upon the active slopes, since such variations are partly due to preconceived ideas as to the necessities of the case, the dimensions of the stone used, and the methods by which the slopes were formed.

In addition to the constructions upon the American coast before referred, random-stone breakwaters exist at Gloucester and Hyannis harbor, Mass., and at Stonington and New Haven, Conn. These breakwaters are only typical of their localities since they are not designed to cover areas which would give protection to the larger class of ocean vessels, but rather to the coastwise commerce of their vicinities.

All breakwater construction in this country has been carried on under governmental appropriations made by Congress at intervals of one or two years. The separate appropriations were seldom more than five or ten per cent. of the estimated cost of the work, and until recently competitive bids were received and contracts entered into for the expenditure of each specific appropriation. Under this system each contractor was obliged to add to the cost of the work, and thereby to its cost to the government, the initial expenses of obtaining and opening quarries, and providing the special plant required, and with each change of contractors the government paid for the expense of organizing, fitting out and starting another. Under the limited tenure with which the contractor held the work, it was impracticable for him to adopt methods and appliances upon a scale large enough to permit the work being carried on with economy to the contractor and consequent advantage to the government.

In a construction of the magnitude of the breakwaters described involving the quarrying, handling, transportation and deposit of several million tons of stone, it is evident that the work can be most economically accomplished when the amount to be done under a specific contract is so large as to justify such an initial outlay for facilities and plant as will permit the work to be carried on upon a large scale. This has been rendered possible upon the Point Judith breakwater, and also upon the new breakwater in Delaware Bay, by Congress providing for a single contract for the entire work at each locality, under large annual appropriations, whereby the work can be completed in about five years. By this plan the contractor is justified in providing appliances and methods for carrying on the work upon a scale which could not be approximated under the former method of separate contracts for each specific appropriation. The resulting economy to the government is evidenced by the fact that under the former methods of contract, the average price of stone deposited in the old Delaware breakwater was about $2.50 per ton, and that delivered during the last thirteen years about $2.30 per ton; whereas the work now in progress upon the new breakwater, at nearly the same locality, costs the government under the method of continuous contract $1.18½ per ton, or a saving over former prices of nearly 50%.

Harbors of refuge are but seldom used by the larger class of ocean steamers, for, unless disabled by accident, they are generally competent to pursue their way during a storm, or else ride out a gale in the open sea with comparative safety; and, unless engaged in the coastwise trade, they would seldom be in a position to avail themselves of the protection of a harbor of refuge, even if it was desired. With sailing vessels or steamers carrying barges in tow and coastwise commerce such harbors are of the greatest utility, and they are placed at localities which make them most convenient of access to this class of commerce when approaching or leaving our ocean coast. During head winds or upon the announcement of dangerous approaching storms the sailing, barge and coastwise commerce have great need for harbors of refuge, and they are utilized to their full value.

THE CHICAGO AND MILWAUKEE ELECTRIC RY.

One of the longest and most interesting of the numerous long-distance electric railways in this country will be the line between Chicago & Milwaukee, two sections of which are now in operation. The Chicago & Milwaukee Electric Ry. Co. has the franchise for the line from Evanston to Waukegan, 31 miles, and the section of this between Waukegan and Highland Park was opened to traffic in July. Work on the southern part of the line is now being pushed, and it is expected that by October it will be completed to Evanston. At that point it will connect with one of the electric lines of the North Chicago Street Ry., with the Evanston branch of the Chicago, Milwaukee &

St. Paul Ry., and with the Northwestern Elevated Ry. when this latter line is completed. There is already a line in operation from Kenosha northward through Racine to Milwaukee, 33 miles, and the direct result of the opening of this line was to lead the Chicago & Northwestern Ry. to take off a large proportion of its local trains on account of the loss of traffic. Between Kenosha and Waukegan is a gap of 16 miles, but we are informed that negotiations are being made for closing this. The sketch maps given in Fig. 1 show the entire route, and also the route of the present line from Waukegan to Evanston. From the latter it will be seen that the line passes through a continuous series of the suburban towns which are such a feature of the lake shore north of Chicago. At Fort Sheridan is the government reservation, and there are manufacturing districts at North Chicago and Waukegan.

The project was originated by Mr. C. E. Loss, engineer and contractor, of Chicago, who made a beginning two years ago by building a line from Waukegan south to North Chicago, 4.4 miles, the average earnings on which line have paid 5% on $120,000. Later on, he built the line between Fort Sheridan and Highland Park, 4 miles, at a cost of $50,000, and this line has shown even greater net earnings. Mr. Loss then secured the balance of the franchises for the through line, and sold the entire project to a syndicate on the basis of the earnings, with a certain percentage for the securing of the franchises. He was then made a director in the new company, and given the contract for the entire line. The company was originally styled the Bluff City Electric Street Ry. Co., but this title was changed to the North Shore Interurban Ry. Co., and the present owner is the Chicago & Milwaukee Electric Ry. Co., the officers of which are as follows: President, George A. Ball; Vice-President and Treasurer, A. C. Frost; Secretary, George M. Seward; Directors (in addition to the above officers), Frank S. Reeves and C. E. Loss.

The line between Waukegan and Evanston will be 31 miles in length, and will lie between the Chicago & Northwestern Ry. and the lake shore all the way to North Chicago, where it will have two subway crossings, one under the Chicago & Northwestern Ry. and the other under the Elgin, Joliet & Eastern Ry. There will not be a single railway crossing at grade. The line will connect about 15 cities and towns having an aggregate population of about 75,000, and the fares will be about half the amounts charged for the same distances on the Chicago & Northwestern Ry.

The road is now a single-track line, with turnouts, but it is double track in Lake Forest, and next season will probably be double tracked throughout. While the greater part of its length will follow existing roads, there will be about eight miles on a private right of way of 25 to 50 ft. wide, and this strip of land will be protected by a five-wire fence of barbed wire. The company is doing the necessary grading to obtain as level a line as possible, and the maximum grade will be a short length of 3% at the subways. The minimum radius of curvature is 55 ft. The two subways will be similar to those in the track elevation work in Chicago, consisting of steel plate girder through spans carried on masonry abutments. That under the C. & N. W. Ry. will carry two tracks. There will only be 150 ft. of trestle work, which will be of substantial construction. Fig. 2 shows a section of a part of the line, the track being laid on a parkway at one side of a macadamized road. A block signal system is in use on that part of the line now in operation.

The track consists of 65 and 72-lb. rails of the "T" and "Shanghai" sections, and also 85-lb. girder rails, all in 60-ft. lengths, with splice bar joints having eight bolts in two rows. The ties are of oak, spaced 18 ins. c. to c., laid in broken stone and slag ballast. The "Protected" rail bond is used, which is a specialty of the Forest City Electric Co., of Cleveland, O. The 72-lb. rail and the rail bond are shown in Fig. 3.

In the business center of each town iron center poles are used, these being 28 ft. long, in sections 5, 6 and 7 ins. diameter. For the other parts of the line cedar side poles, with bracket arms, are used, the poles being 30 ft. long and 7 ins. diameter at the top. The high-voltage transmission wires are supported on glass insulators carried on wooden cross arms on the side poles. Each pole is painted, and those carrying the alternating-current lines have danger notices stenciled upon them. The span wires are of 5-16-in. galvanized wire, and the trolley wire is of No. 00 B. & S. gage.

The company is aiming to build a first-class railway, suitable for running trains at a speed of 25 to 30 miles per hour with comfort and safety. The line now under construction is being built for a contract price of $25,000 per mile, this being for a single track, but the price includes the private right of way, five acres of land near Fort Sheridan for the power house and car house, the double-track subway under the C. & N. W. Ry., and about two miles of macadam paving 18 to 20 ft. wide, with drainage, catchbasins, etc. It also includes a cash bonus of $10,000 as compensation on account of franchises.

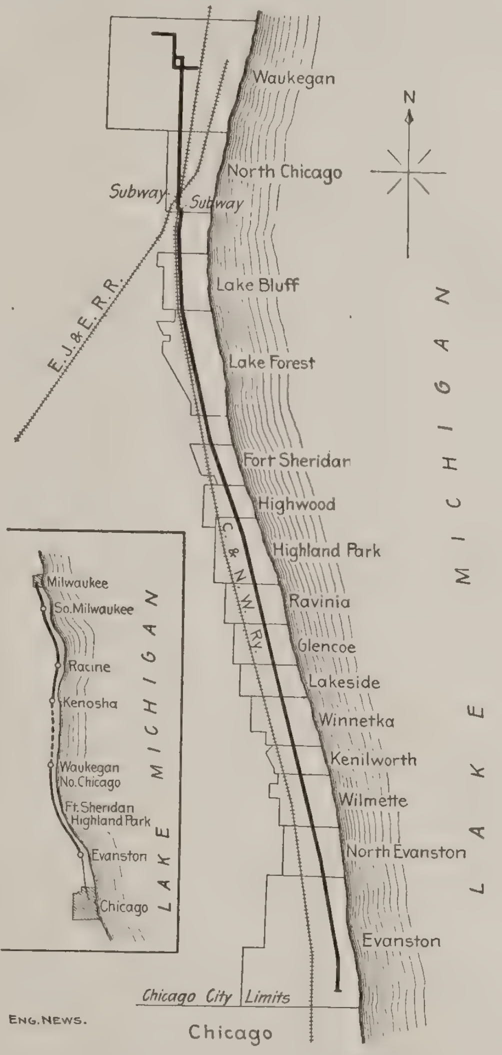

Fig. 1.—Sketch Maps Showing the Present Line and Completed System of the Chicago & Milwaukee Electric Ry.

Four-wheel and eight-wheel cars will be used, all having vestibuled ends and transverse seats, and the motor cars will haul trailers. The motor cars will have General Electric motors of 35 HP. for the smaller and 50 HP. for the larger cars, of the latest type for high acceleration, enabling the car to attain its full speed of 30 miles per hour in 19 seconds. Arrangements have been made to carry freight and light baggage, and perhaps mails also. There are now in use ten 30-ft. cars built by the St. Louis Car Co., of St. Louis, Mo. Two passenger cars of the interurban type, and two combination passenger and baggage cars are being built by the Pullman Palace Car Co., of Chicago, Ill. These four cars will be 38 ft. long, each mounted on a pair of Peckham standard railway trucks and equipped with two 50-HP. motors.

The transmission system of this long-distance, high-speed, electric railway is of particular interest, the aim having been to devise a system which will require but a minimum outlay in first cost, but which can be added to as the load increases in a manner consistent with the original installation. It was also required that it should operate with a fair degree of economy from the start, and at the same time be capable of the highest operative efficiency when eventually completed. The great cost of copper for the feeders which would have been necessary to operate the road by means of a direct-current station situated at the center of the line prohibited the use of the direct-current system, and it was also recognized that the operation of two power stations for a road of this size, or of a booster system operated from one power house, would not give a good efficiency.

The plan adopted, and the one which is thought to combine all the above requirements, consists of a combination direct-current and three-phase alternating-current distribution system, with a single generating station placed at the center of the line. The sections of the road adjacent to the power station are supplied with direct current from the power house itself. Sections of the line at a distance from the power house get their supply of current from sub-stations. These sub-stations each contain a rotary converter, consisting of a three-phase alternating-current motor and a direct-current generator combined in one machine. The sub-station motors are supplied with power over a high-tension transmission line consisting of three small copper wires extending back to the power house. The direct current from each sub-station is distributed to the trolley by means of the usual system of feeders extending in both directions. The location of these sub-stations and their distance apart is governed by the conditions of traffic and somewhat by the nature of the grades along the line.

The power station is located at Highwood and the sub-station for the operation of the northern portion of the road is situated near the southern limits of North Chicago. Connecting the power house with the sub-station is an eight-mile, 5,500-volt, three-phase transmission line of three No. 8 wires. From the sub-station the No. 00 trolley wire is reinforced by a No. 0000 feeder extending four miles south and a No. 000 feeder extending 3½ miles north.

It is claimed that there is no reason why a road 100 miles in length should not be operated by this system from one power house located either at the center of gravity of the system or upon a site possessing peculiar advantages of rail and water facilities. The small investment required for copper will appeal to the investor, while the possibilities of economies of fuel and labor due to the concentration of the power generating apparatus into one station makes the proposition a promising one to the engineer. The development of this road and the economic results of its operation will be awaited with considerable interest.

An objection sometimes urged against the three-phase system is the possibility of danger from carrying such a high voltage through the feeder system, but it is to be remembered that this is a medium or low voltage compared with that of electric lighting and power systems now in use, notably about Niagara and in the West.

The power house and car barn will be of brick, with steel roof trusses, and a plan of the building and plant is given in Fig. 4. The present plan consists of one 400-HP. engine and one 250-K-W. dynamo, but the complete plant will comprise two additional tandem, compound, condensing Corliss engines of 800 HP. each, and four additional direct-connected General Electric composite generators of 250-K-W. capacity. Steam will be supplied by six Cahall-Babcock & Wilcox water-tube boilers of 250-HP. rated capacity, fitted with the Hawley down-draft furnace. These boilers will be arranged in three pairs or batteries, and three boilers are now in place. The boiler setting is such as to make each battery entirely independent of the brickwork which surrounds it. The feed water is taken from the city mains, and supplied to the boilers by the boiler feed apparatus of the Q. & C. Co., which has recently been described in our columns. The fuel is slack coal, which is delivered in front of the boilers directly from the cars. Each pair of boilers will have a fuel economizer, with the by-pass flue passing underneath. The steel smokestack is of sufficient capacity for eight boilers, in case it should be necessary to eventually add another pair of boilers.

The engines are of the horizontal type, and run at 125 revolutions per minute. The 400-HP. engine now in service has cylinders 17 × 36 ins. and 30 × 36 ins., and a flywheel 14 ft. in diameter, weighing 40,000 lbs. The governor is of the Provell inverted type, fitted with an automatic safety stop to prevent the engine running away. This stop blocks the governor balls up except in the event of the governor belt breaking, and the device requires no manipulation in starting or stopping the engine.

The present engine is of the side-crank type, but the two future 800-HP. engines will be of the center-crank type, as shown in Fig. 4. Each engine is designed to sustain an overload of 100%, this provision being made for emergency service, when the engines can be made to develop a power greatly in excess of their rating by admitting high-pressure steam into the receiver through a reducing valve.

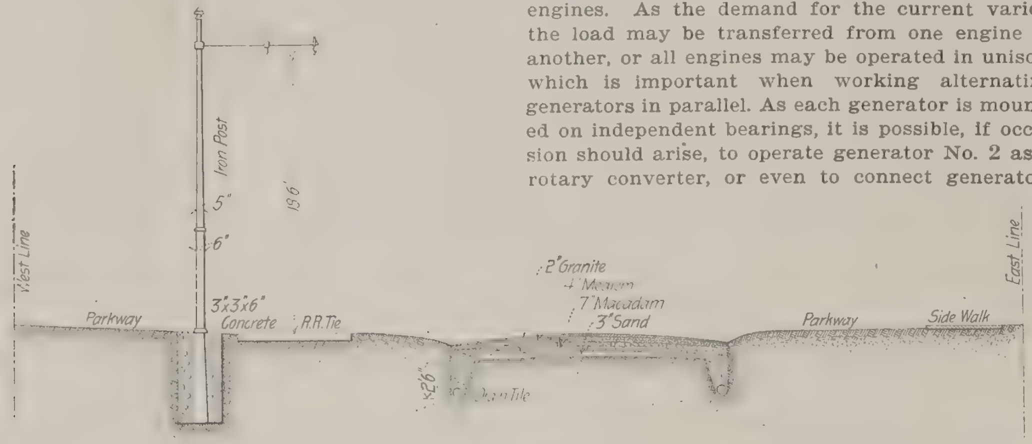

FIG. 2.—CROSS-SECTION OF ROADBED, SHOWING PARALLEL MACADAMIZED ROADWAY AND PARKWAY; CHICAGO & MILWAUKEE ELECTRIC RY.

Special attention is called to the electrical generating plant, two types of generators being employed. Generator No. 1, which is next to the 400-HP. engine, marked No. 1 in Fig. 4, is an alternating three-phase machine, made by the General Electric Co., and has a capacity of 250 K-W. at 125 revolutions per minute. It has 24 poles, and, therefore, delivers a three-phase current of 25 cycles per second. This current is generated at a potential of 5,500 volts, ready to be delivered directly to the transmission lines without the use of transformers. Generators Nos. 2 and No. 4 are combination machines, and have also a capacity of 250 K-W. when running at 125 revolutions per minute. Each of these generators, however, can deliver its output either as direct current or as three-phase current. It has but one armature, but the windings of this armature are connected on one side to a comutator and on the other side to collector rings. The potential of the direct-current end is 600 volts, while the three-phase current is delivered at a voltage of 380. The generator can deliver its rated capacity of output from either the comutator or the collector rings. It can thus be used to supply current directly to the trolley passing in front of the power station, or can be used to operate the motors in the sub-stations, or for both purposes at the same time, dividing the load in proportion to the demand.

These two generators, as above noted, are of considerably lower voltage than the other three, and when their three-phase current is transmitted to the sub-station its potential is raised from 380 volts to 5,500 volts by means of static transformers placed in the basement, as shown in Fig. 4. The transformers are cooled by a blast fan operated by a 1-HP. induction motor.

The engines and generators are connected by means of the Arnold system, which has already been described and illustrated in our columns, and which has been adopted in a number of power stations. Each generator is mounted on a quill or hollow shaft, and suitable couplings connect this solid shaft with either of the engine shafts or the generator quills in such a manner that each generator can be operated by more than one engine. Thus, engine No. 1 can run either or both generators No. 1 and No. 2, while engine No. 2 can be used to drive four generators when they are eventually installed. In case of a break-down to any engine, the other engines in the plant can be made to carry an increase of load by the method already described. The flexibility of this system makes it unnecessary to install a reserve unit, as an accident to an engine would not cripple the entire unit. This system is also particularly adapted to a station of this character, containing two different types of generators. When the load is light, the road may be operated from the combined alternating-current, direct-current generator, which is always available from two engines. As the demand for the current varies, the load may be transferred from one engine to another, or all engines may be operated in unison, which is important when working alternating generators in parallel. As each generator is mounted on independent bearings, it is possible, if occasion should arise, to operate generator No. 2 as a rotary converter, or even to connect generators Nos. 1 and 2 so that they could be used in the same manner.

Each sub-station will contain the static step-down transformers, the rotary converter and a storage battery. It has not been considered necessary to have this equipment in duplicate, as it is intended to mount the machinery needed for a sub-station (static step-down transformers and one rotary converter) upon a truck fitted with motors. In case of break-down at any sub-station, the battery can be relied on to supply current for several hours during which time the portable reserve sub-station equipment can be propelled to the crippled station and connected ready to operate until the repairs have been made.

The storage battery in a sub-station of this character has many advantages. It supplies all the sudden and excessive demands for current, due to the fluctuating load, peculiar to a road of this kind, and operating heavy trains. The rotary converter can be made to carry a fairly average load, while in turn the generating machinery at the power house can be oprated under constant conditions, and this feature of steady load will tend towards fuel economy at the generating station. As the sub-station batteries are able to respond for short periods to an excessive demand, the generating station is relieved from the necessity of supplying the occasional maximum load, and consequently machinery of much less capacity is required at the station than if the batteries were not used. There is also a correspondingly reduced investment required for transmission lines and rotary converters.

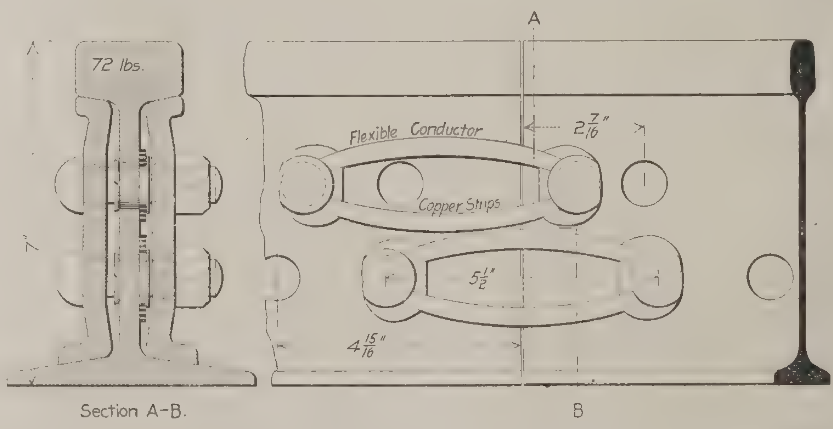

FIG. 3.—RAIL AND JOINT, SHOWING THE PROTECTED RAIL BOND; CHICAGO & MILWAUKEE ELECTRIC RY.

There is still another advantage peculiar to this combined direct-current system of distribution. The self-induction of the alternating-current motors in the sub-stations causes "leading" and "lagging" currents, which may become extremely troublesome. The best condition for operating is when the power factor of the curcuit is unity; or when the apparent energy is equal to the real energy. The strength of the motor field can be adjusted at any given load so as to neutralize the inductance of the line, and leave the current nearly in phase with the E. M. F. If the motor can operate at or near this given load, the power factor will not depart far from unity and the circuit will act like a continuous-current line. If the load varies, however, to any great extent, the resulting "false current" may compel the transmission over the lines of a current greater than that really required to operate the motor. The storage battery furnishes a reservoir to receive or deliver energy as the load varies, enabling the rotary converter to carry a practically steady load, and thus helping materially in maintaining an electrical balance in the alternating-current circuits. It is considered that as the road is extended and the traffic becomes heavier, the conditions of the service will probably make the installation of a battery at the main power house a desirable investment.

The plans for the power plant and transmission system were prepared by Mr. B. J. Arnold, of Chicago, who is Consulting Engineer for the company, and it will be seen from the foregoing description that these plans include some decided novelties in electric railway engineering practice.

The principal contractors for materials are as follows: Dynamos, motors and electrical equipment, the General Electric Co., Schenectady, N. Y.; steam engines, the Filer & Stowell Co., Milwaukee, Wis.; boilers, the Aultman & Taylor Machinery Co., Mansfield, O.; rails, the Johnson Co., Lorain, O.; wire, John A. Roebling's Sons Co., Trenton, N. J.; cars, St. Louis Car Co., St. Louis, Mo., and the Pullman Palace Car Co., of Chicago, Ill.

The general contractors and builders of the line were C. E. Loss & Co., of Chicago. Mr. Loss, who was the original projector of the line, as already noted, has made a specialty of electric railway construction. In addition to the Chicago & Milwaukee line, he has also built the Pullman, the Calumet, the Englewood & Chicago,* and the Kankakee electric railways, in Illinois; the Hammond, Whiting & East Chicago, and the Broad Ripple railways in Indiana; the Sheboygan and Waukesha electric railway in Wisconsin; the Cleveland and Chagrin Falls and the Ironton electric railways in Ohio; the St. Charles and the Orleans railways in New Orleans; and the line from Jalapa to Coatepec in Mexico.

In the earlier part of this article we pointed out that while the present Chicago & Milwaukee line extends only from Chicago to Waukegan, there is also an electric railway in operation south from Milwaukee to Kenosha. This line is owned by the Milwaukee, Racine & Kenosha Electric Ry. Co., of which Mr. Matthew Slush is President. The line is 35 miles in length, of which seven miles are on a private right of way. The cars run into Milwaukee over the tracks of the Milwaukee Electric Ry. Co., and have their terminal at the City Hall, the arrangement between the two companies entitling every passenger going into the city to a transfer to any point on the latter company's lines. The track is laid with 72-lb. rails and is ballasted with broken stone. The maximum grades are 3% and the sharpest curves of 60°. The power station is at Racine, and contains two compound engines of 1,500 HP. and two Westinghouse dynamos of 1,200-K-W. capacity. Long eight-wheel cars are used, having a 50-HP. motor on each truck. Each car will seat 50 passengers, and has toilet-room, smoking-room and a drinking-water tank. The cars are run singly, the time allowed being 2 hours 20 minutes, and there are 18 regular trips each way daily, besides which a number of special cars are run. Packages are carried, and in June a combination car was put on to carry mail and express matter, packages, fruit, milk, etc. The passenger fare is 70 cts., or $1 for the round trip.

SIXTH ANNUAL MEETING OF THE SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION.

The sixth annual meeting of this society was held in the Walker Building of the Massachusetts Institute of Technology, in Boston, on Aug. 18, 19 and 20. This time was selected because the meeting of the American Association for Advancement of Science was to be held at the same place in the week beginning Aug. 22, and the meeting of the American Mathematical Society and the Conference of Astronomers and Physicists were to be held on the same dates (Aug. 18-20), thus making it convenient for the professors of engineering schools, who compose the greater portion of the membership of the Society for the Promotion of Engineering Education, to attend the meetings of the other societies. The society has now reached a membership of about 270, and about 70 members were registered as in attendance, a very large proportion for any scientific society whose membership is scattered over the whole country. The meetings were of exceptional interest and value. The papers presented were, many of them, of a high grade, and the discussions were brisk and full of interest. The members seemed to be animated with one common purpose, to improve the courses of education in our engineering schools, and in their consideration of this important subject they viewed it from all sides, not merely scrutinizing the minor details of the courses of study, but treating it from the broader standpoints of enhancing the dignity of the profession and of advancing the civilization of the world. Two notable addresses in which this broad view was taken were the address of the president, Prof. J. B. Johnson, on "A Higher Industrial and Commercial Education an Essential Feature of Our Future Material Prosperity" (Eng. News, Aug. 18), and Dr. R. H. Thurston's address on "The Correct Theory and Method of Organization and Conduct of Professional Schools."

The first session was held on Thursday morning, Aug. 18. After the reports of officers, election of members and other general business had been attended to, Prof. Johnson delivered his address. This was followed by a paper by Prof. Gaetano Lanza, of the Massachusetts Institute of Technology, of which we give an abstract below:

The Class-Room and the Laboratory in Their Mutual Adjustment to the End of the Most Efficient Instruction.

In giving a student an engineering education we wish to fit him, as thoroughly as possible, to grapple successfully with the duties and responsibilities of his profession, not only those of a technical nature, but also those which he must assume as an engineer and as a man.

Pure science and literature should not be neglected in his training.

To impart to the student a thorough mastery of scientific principles far outweighs in importance anything else that can be done for him, and this is the chief function of an engineering course.

The class-room work forms the basis of the course, and the laboratory work, to serve its purpose, must be based upon the class-room work which has preceded it, must be thoroughly co-ordinated with it, and must be made to depend upon it, to use it, and to serve as an aid to illustrate the principles involved. Without the laboratory work, the modern development of our engineering schools would have been impossible; for the laboratory work has not merely served to illustrate and elucidate the class-room work, but has also reacted upon it and caused the class-room work to be so modified as to accord with the facts; and thus has been produced an enormous development in the class-room work itself.

The functions of the engineering laboratory are partly to emphasize and illustrate the work of the class-room, partly to drill the students in performing carefully and accurately such experimental work as they are liable to be called upon to perform in the practice of their professions, and partly to teach them to carry on experimental investigations.

In order to fulfill these purposes there should be an intimate relation between the class-room and the laboratory work, and the student should be made to work up the results of the tests in the light of what he has learned in the class-room.

Any organization which does not tend to preserve the most intimate relation between the two, is not for the best interests of the students and should not exist.

A brief discussion followed, in which it was generally admitted that all of Prof. Lanza's points were well taken. The next paper, by Prof. H. B. Smith, of the Worcester Polytechnic Institute, was entitled:

Note on the Organization of an Electrical Engineering Laboratory.

The paper discusses briefly the importance of, and method of securing, system and flexibility in the equipment of an electrical engineering laboratory, whether for routine undergraduate work or for advanced research, and described the construction of a laboratory designed by the author to secure these ends.

In the afternoon visits were made by many of the members to several departments of the Massachusetts Institute of Technology. The evening was devoted to hearing a long address by Prof. R. H. Thurston, of Cornell University, The following abstract was furnished by the author and printed in the programme:

The Correct Theory and Method of Organization and Conduct of Professional Schools.

The correct theory and method of organization and conduct of professional schools, generally; the special methods applicable to (a) professional schools of engineering; (b) to trade schools; (c) to manual-training schools; (d) to mixed professional and educational curricula. The subtopics under this subject are:

(1) In the technical high-school, what properly determines the form and extent of its technical and other courses?

(2) In such schools, what should be the extent and character of what may be termed the distinctive and essential entrance requirements? What the non-essential requirements?

(3) In the technical college, what should be the nature and extent of these two different classes of demands? What courses should be offered in response to the demand for technical instruction from people whose sons must go directly into business from the lower schools if they cannot obtain a directly useful technical training?

(4) The professional engineering school, now being evolved—the distinctly professional school, having the same position and purpose as, in other professions, the law and medical schools—must soon, if not at once, require definition and delimitation from the academic colleges. What should be the entrance requirements?

(It is understood, of course, that what is practical is limited by the practicability of the existing schools providing it, and that what is desirable is determined by the demands of the profession relating to distinctively professional courses.)

(5) To what extent should the existing views and traditions of the people generally, and the prejudices of the academic teachers and monastic scholars, be deferred to, in the construction of the curriculum of the professional school of engineering, in which, as must be assumed, the work is to be professional training and not, in the accepted sense of that word, education?

(6) If, as is the fact in the state of New York, a body of academicians—its Board of Regents—assumes to control and to dictate to the faculties of the professional schools, what course should be taken to secure independence from such inexpert direction and to insure the management of professional institutions by professionally expert faculties?

(7) Assuming that it is obvious and is admitted that the form and extent of a professional course must be simply that which is demanded by the character of the work of that profession, and that it may be taken for granted that students entering such institutions will, as a rule, if not invariably, have sufficient intelligence and judgment to secure just as much of liberal education, of real education, in the accepted sense, as possible—what should be the length, the extent, and the limitations of such courses in the distinctively professional school?

(8) In such institutions, what other than professional work, if any, should be offered? What entrance requirements would suffice? Should the policy be that of a wide range of non-essential entrance requirements and high academic culture, with, necessarily, few students; or should the entrance requirements be restricted to characteristic and essential introductory work? With, presumably, unobstructed freedom of entrance of all classes and conditions of men; provided only that the poorest of them has attained competence in preparation in the essential requirements for entrance upon professional studies as taken up at the beginning?

(9) In the technical high-school, and in the technical college, of the more common sort in this country, in which some educational work is usually necessarily offered, where should the lines be drawn in respect to entrance requirements, and, in constructing the courses themselves, in such semi-professional schools?

(10) What are the similar conclusions respecting trade-schools and what respecting the manual-training schools now becoming common in our cities?

(11) How shall we classify all these various, as yet undefined courses and schools, in order to secure some definite principle of organization and operation?

The morning session on Friday began with a discussion of Prof. Thurston's paper. Prof. Woodward, of the Columbia School of Mines, pleaded for adherence to broad lines of general training and avoidance of too great specialization. He advocated that such inefficient management as the New York Board of Regents should be thrown out of existence. Prof. Fletcher, of Dartmouth, argued for the purely professional school of engineering, which leaves all elementary work to other schools.

The first paper presented was Prof. Haynes' description of the mounting and use of a spherical blackboard, read by Prof. Eddy, of Minneapolis. The importance of such a piece of apparatus in teaching spherical geometry, spherical trigonometry and astronomy was clearly shown, and the best methods of its use briefly explained.

A report of the Committee on Uniformity of Symbols was followed with interest by the audience, who seemed to have all suffered inconvenience from the confusion of various illogical symbols used in many sciences. The committee urged the universal adoption of symbols, as few in number as possible, but sees no way at present of securing this result. Two years ago a committee on this subject reported systems of symbols for different branches of engineering, which are published in the last volume of the "Transactions," but that committee's report was deemed unsatisfactory by many members, and a new committee on the subject was then constituted. This committee now reports that it is unable to prescribe a system of symbols which is likely to meet with general favor, and made two recommendations, first, that the consideration of the subject of symbols be dropped, and second, that a new committee be appointed to consider definitions of the terms used in engineering. The first recommendation was adopted unanimously, but the second was laid on the table by a large vote, and thus disapproved, and the committee was then discharged.

The first paper of the session was entitled "Some Phases of Engineering Education in the South," and was read by J. J. Wilmore, Professor of Mechanical Engineering, Alabama Polytechnic Institute.

The difficulties to be met by engineering education in the South are in some respects peculiar to the section, and in others, common to all sections. The problem of preliminary preparation is one, the solution of which all can share. In some of the southern states, however, it is more trying than elsewhere. This problem, complicated by the demand for a multiplicity of subjects other than engineering subjects, makes the arrangement of a satisfactory course of study difficult.

No college ever yet had as much money as it needed, but in the South the lack of funds is more keenly felt than in other sections, for the following reasons:

(1) The necessity of separate institutions for white and for colored students. The funds that might support one are insufficient for two.

(2) The absence of personal bequests and donations to white colleges in the South.

(3) The fact that lower fees are charged the students than in other sections of the country.

From the statistics of nine colleges in each section, selected to be as nearly representative as possible, the income per student for the northern colleges averages $242, and for the southern colleges $172. The average number of students per instructor in the northern colleges is 10.7, and in the southern colleges 12. The greatest income per student is $440, and the least $64. The smallest number of students per instructor is 6.2, and the greatest, 15.6. These statistics are based on the total attendance, and while not an absolute index of the engineering work, should give relatively the conditions in the two sections.

The inertia of the old prejudice of practice against theory is still an important factor in southern industrial management. This makes it difficult for our students to get positions which they are qualified to fill, without first undergoing a year or two of drudgery from which they secure little, if any, benefit.

The conditions, however, improve from year to year, and the prospect for the future is far from discouraging.

A paper was then presented by Prof. J. P. Jackson, of the Pensylvania State College, entitled;

"Electricity in Engineering Courses Other Than Electrical."

The present extended use of electricity in industrial undertakings has made a knowledge of its control indispensable to the well-rounded engineer.

College courses preparing for the older engineering professions were established while electricity was of small service. Through human inertia these courses have tended to continue on their old lines. The present time, therefore, finds training in electricity far from satisfactory in engineering courses other than electrical.

The work usually assigned is the electricity and magnetism of the general college physics course, with possibly one term on its applications. No time is given to a vigorous advanced treatment of the subject from an engineering standpoint. The college physics course might as well be depended upon to give the requisite training in applied mechanics or thermodynamics.

In addition to the work now usually scheduled, a thorough training in the laws of direct and alternating currents, as they apply to the practical utilization of electricity, should be added. This should be taught by an engineer, and should be assigned time comparable to that given the steam engine, hydraulics and hydraulic machinery, etc. This time could be obtained with advantage by cutting out special work. An outline of such a course is included in the paper.

As scientific knowledge increases, engineering courses must give more time to fundamental principles at the expense of mere technical practice. Hence such courses tend to converge.

If electrical engineering studies are to be satisfactory they must be under the supervision of an engineering department, and should not be taught by instructors in the departments of physics.

The next paper was by Mr. F. L. Dunlap, of the Worcester Polytechnic Institute, and was entitled "A Course in Industrial Chemistry for Technical Schools." The course, he said, should be directed toward practical results. His own students are sold raw products at their market value, and, after being purified in the laboratory, the refined material is purchased from them, thus stimulating their activity by a financial gain, through their chemical skill.

Prof. Brown Ayres, of Tulane University, Louisiana, in the discussion which followed, spoke of industrial chemistry in its relation to the development of sugar production. The American sugar chemists, he said, have nearly all come from abroad, because they are not rightly educated in the United States. The great increase in our sugar business, owing to the acquisition of new cane-raising territory, will greatly increase the demand for this class of chemist.

The next paper was by Prof. W. K. Hatt, of Purdue University, on

A Laboratory Apparatus for Impact Experiments.

Longitudinal impact is produced by the fall of an 845-lb. cast-iron weight or hammer on a specimen of steel rod. The rod is held at each end by conical wedges fitting in steel bushing pieces. The hammer is fixed to the lower end of the specimen, the lower bushing bearing against a shoulder made in the core of the hammer.

The combination of upper bushing, rod, and hammer, is lifted to a desired height and then released. The upper bushing is caught in the descent by cross pieces fixed to the uprights of the apparatus, and rupture of the specimen results. The circumstances of the impact are recorded on a revolving drum by a pencil attached to the hammer. The resulting curve furnishes data from which the ultimate resilience, elongation, time of impact, etc., are obtained.

The resilience is worked up in two ways: (1) by the application of the principle of work and energy to the descending weight, and (2) from the load-elongation diagram, whose abscissæ are the elongations of the specimen and whose ordinates are the corresponding forces, computed from the known mass of the weight and its retardation.

The apparatus illustrates to the student some principles in mechanics and some phenomena of rupture, and may be applied to purposes of research.

In the afternoon an excursion was taken by many members to examine the Boston subway under the Common, which was built to relieve the congestion of the streets by trolley cars, and the machinery for its ventilation, which is highly successful.

At the evening session the first paper was read by Prof. S. A. Reeve, of the Worcester Polytechnic Institute. It was entitled,

The Direct Study of Thermodynamics.

Prof. Reeve has been very successful in the use of the temperature-entropy diagram, the use of which he illustrated by several large drawings. The student should first, he said, be shown that heat and other forms of energy change places, and that energy is one and indivisible, appearing in different costumes as mechanical and electrical. He must then learn to see the two elements of force and mass in all energy, gaining a clear idea of what energy is.

There is nothing more mysterious in the passage of heat from a body of high temperature to one of lower temperature than in the flowing of water down hill or the corrosion of a metal by an acid. Heat runs down temperature as unavoidably as the stone falls from the hand when released. Heat engines and their opposite, refrigerating machines, are the apparatus to be used in thermodynamics instruction.

Prof. Peabody, of the Massachusetts Institute of Technology, and author of a text-book upon thermodynamics, proceeded to argue with a view to disprove among other things the assertion that it is of prime importance to develop an understanding of what energy and mass are in the minds of engineering students. Prof. Peabody fervently wished that he himself might first understand what these primary foundations are, but humbly confessed his ignorance. He stated that the chief reason that students found so much difficulty in thermodynamics was that they were not sufficiently well grounded in the calculus, and that thermodynamics lost all terrors to a student who had properly mastered his mathematics. Prof. Reeve was unfortunate in not having any defenders of his method of teaching among the audience. It would be well if teachers of thermodynamics would investigate it more carefully. If there is an easier way of penetrating thermodynamic mysteries than by first mastering differential equations it ought to be more generally known and followed.

The report of the standing committee on Entrance Requirements was then presented by Prof. Tyler. This committee is doing good work in collecting and publishing the statistics of the requirements of different schools, and in endeavoring to bring about some degree of uniformity. The subject was referred to the council, with instructions to take action upon several recommendations made by the committee, one of which is that of enlarging the committee so as to secure representation from different sections of the country.

The paper was read by Mr. W. B. Hoag, professor of civil engineering in the University of Minnesota, upon "A Course in Highway Engineering for Civil Engineers." The author made an earnest plea for a campaign of education upon the necessity of good roads, saying that road missionaries are needed before road engineers, and the farmers taught the immense profit that would accrue to them from good highways to their local markets. Now they are content to gage their loads by their estimate of the state of the roads, then trust to their luck and to Providence for the outcome.

Prof. Hoag briefly sketched the history of road-making from those used in the construction of the pyramids and the Roman successes in paving, down to the developments of modern macadamizing. He claimed that the art of road-making has not kept up with the advance in other arts, and that the United States is lagging in the rear of every other nation of equal general progress, in this very vital test of civilization.

The most interesting feature of the session on Saturday morning was a short extempore address by W. T. Sedgwick, Professor of Biology in the Massachusetts Institute of Technology, on "The Claims of Sanitary Science to a Place in the Curriculum of Engineering Education."

Prof. Sedgwick is a brilliant lecturer, and the abstract of his address printed in the programme, which we give below, gives a poor idea of the vigor with which he handled the subject. The abstract says:

> The strength of the claim upon a curriculum already overcrowded depends simply upon the relative efficiency of the subject in contributing to the end in view, and this efficiency being in many cases difficult or even impossible to determine with any accuracy, opinions will differ, and curricula will differ, accordingly, in an entirely natural and probably very wholesome way.
>
> A very great amount of modern engineering is essentially sanitary. Water supply, with its reservoirs, filters, dams, conduits, pipes, pumps, meters; sewerage, with its plumbing, drains, pumps, disposal works, sludge basins, and purification problems; warming and ventilation, with their questions of humidity and conductivity, affecting the health and ill-health of man, as well as questions of the purity of the air in respect to gases and micro-organisms; the construction of halls and buildings, of factories and tunnels, to be used by human beings, subject to infection, varying in lighting and air space; all of these have either their origin or their proper control in modern sanitary science.
>
> It seems to the writer proper and wise, therefore, to provide a short course of instruction in the fundamentals of this subject; and such a course, consisting of fifteen lectures, with demonstrations, has now for some years been given by him with much success to civil engineers, architects, and others, in the Massachusetts Institute of Technology. A comprehensive survey of the course and its results appears in the complete paper.

In the discussion, a member said that the course of 15 lectures described by Prof. Sedgwick should be taken as a part of a liberal education by all students in colleges, rather than having it confined, as he suggested, to civil engineering students. The subject was not only of vast importance to the whole race of men, but, as presented by him, was essentially a culture study, in giving the student some insight into many different sciences and expanding his intellect in a greater degree than could be done by any course of 15 lectures on almost any other subject that could be named as a branch of liberal education. This view was generally favored by others who took part in the discussion.

Other papers presented at this session and discussed very briefly on account of lack of time are given in abstract below:

Undergraduate Thesis Work.

This paper was read by Edgar Marburg, Professor of Civil Engineering, University of Pennsylvania. and was in abstract as follows:

> Former discussions of this subject indicate marked differences of opinion. These differences are probably more apparent than real. This paper is intended chiefly to elicit discussion.
>
> The thesis is not regarded as a test of the acquirements or capabilities of the students. It is recognized rather for its value in affording more advanced and specialized training. The general character of the subject should be determined by the student's predilection, or by the nature of his prospective employment, or better, by both. Its choice should always be selected in consultation with the instructor.
>
> In civil engineering, a design or an occasional resume requiring extended reading and study is preferable, generally speaking, to such so-called original experimental work as the average undergraduate is capable of. In a design, an excessive amount of routine work can be avoided; in an experimental subject, this is usually impracticable. The value of the former, educationally, is at least as great; as a means of professional training, usually much greater. In an experimental thesis there is more danger that the best interests of the student will not be held strictly in view.
>
> The curriculum requires careful adjustment. Assuming a two-term year, courses most essential to thesis work should be completed during the first term. There should be less prescribed work for the second. The choice of subject and certain preliminaries should be disposed of during the first term; weekly periods should be assigned to thesis work throughout the second. The practice of not appointing fixed hours is deprecated.
>
> The student should be left to his own resources within reasonable limits only. The work throughout should be under the conscientious supervision of the instructor. The undergraduate requires and should receive certain assistance that reference books do not and cannot supply.

The Construction of Models by Students as an Aid in Teaching Descriptive Geometry.

This paper was read by Henry S. Jacoby, Associate Professor of Bridge Engineering and Graphics, Cornell University.

> Probably no course of study in the curriculum of engineering students makes such demands upon the imagination as a thorough course in the elements of descriptive geometry. The lack of preliminary training in this respect renders the subject difficult to a number of students. Some improvements, however, has been made recently in the attempt to educate the student's imagination to a proper comprehension of the forms in solid geometry.
>
> There is a wide gap between the single projection used in geometry and the two or more projections employed in descriptive geometry. Models are used extensively, but the most of them relate to the latter part of the course, or to the application of the elements. The models available only in the class-room are insufficient for the best results. The student needs the model during lesson preparation. He can make the most useful ones with little expenditure of time and labor from cardboard, thread, and wire.
>
> The chief value of a model lies in the effective aid in securing, at the beginning of the course, clear conceptions of the relation of the figure in space to its projections, and in that it can be viewed in those directions which show that the projections form adequate representations of the object for the purposes of the constructive arts. It is not necessary to have models for all the principal problems, but only for selected ones. In the study of the tangency and intersection of surfaces and the form of warped surfaces, the class-room models answer the purpose with but few exceptions.

The Training of Engineers for the Maintenance of Way Department on Railroads.

This paper was read by J. C. Nagle, Professor of Civil Engineering and Physics, Agricultural and Mechanical College of Texas, and was in abstract as follows:

> This paper discussed the question of the proper qualifications of those entrusted with the responsible duties of maintenance of way on railroads, and took the ground that all such work should be entirely divorced from the operating department, being placed under engineering control. As to the training that engineers of maintenance of way should have, as well as that of others in responsible positions, it was maintained that an engineering college or university course is essential; but as these institutions are now equipped, the requisite knowledge of details cannot well be given. A plan whereby this may be accomplished was suggested, and an experiment upon one of the leading railroads of Southern United States was cited to show that young engineers can be found without difficulty, ready to serve as apprentices in any capacity, provided that hope of advancement is held out to them. It will be contended that roadmasters and superintendents should be engineers (and even section foremen should have such training as an engineer finds necessary), but at the same time they should have served in the lower ranks of the track force in order to thoroughly understand every detail of their work. This would require the co-operation of the railroads and technical schools, but in the end would tend towards the betterment of both—the engineering school adapting the courses of instruction to the needs of the railroads, and the latter profiting by the use of technically trained men in every branch of the maintenance of way department.

In the afternoon an excursion was taken down the harbor, by courtesy of the chief engineers of the Boston and Metropolitan Sewerage Systems, to visit the pumping plants and the outfalls of both systems, and also the plant now under construction for the utilization of garbage by the Arnold process.

THE POPULATION OF CONTINENTAL EUROPE is given by "La Revue Francaise de l'Etranger" as 380,000,000, made up as follows:

European Russia and Finland	106,200,000	Turkey in Europe	5,800,000
Germany	52,300,000	Roumania	5,600,000
Austro-Hungary	43,500,000	Portugal	5,000,000
		Sweden	5,000,000
		Holland	4,900,000
The United Kingdom	39,800,000	Bulgaria	3,300,000
		Switzerland	3,000,000
France	38,500,000	Greece	2,400,000
Italy	31,300,000	Denmark	2,300,000
Spain	18,000,000	Servia	2,300,000
Belgium	6,500,000	Norway	2,000,000

The density per sq. kilometer, which is about equal to 0.386 sq. miles, is: Belgium, 220; Italy, 169; Holland, 149; England, 126; Germany, 97; Switzerland, 73; France, 72; Austria, 69; Spain, 36; Russia, 20. While the annual increase of the population of Russia has been 1.45 for every 100 in the last ten years, that of Germany has been 1.15, of Austro-Hungary 0.96, of England 0.35, of Italy 0.45, of France 0.08. If this rate is continued, the populations at the end of 100 years will be: Russia, 228,000,000; Germany, 106,000,000; Austria, 79,000,000; England, 65,000,000; Italy, 44,000,000, and France, 40,000,000.

EDITORIAL 136
The Reduction in Railway Transportation Rates in the United States.
LETTERS TO THE EDITOR 137
Notes of an Engineer in Colorado.

THE NEW WARSHIP PROGRAM of the naval board of experts calls for the speedy construction of fifteen ships, of which six are to be heavily armored fighting ships; six are to be small protected cruisers, and three are to be midway between these extremes. The three battleships are to have 13,500 tons displacement on 25½-ft. draft, and have a minimum speed of 18½ knots with all stores and coal aboard. The three large armored cruisers will have 12,000 tons displacement, a speed of 22 knots and a steaming radius of 10,000 knots. There would also be three semi-armored and protected cruisers, of a highly improved "Olympia" type, and six 16-knot protected cruisers of an improved "Detroit" type, with 13,000 knots steaming radius. All these ships will be sheathed with oak and copper. The battleships will have armor over the entire ship, 12 ins. thick amidships, tapering to 5 ins. at the bow, and made of Krupp-Harvey steel. They will carry four 12-in. guns of extra length, for the use of smokeless powder; the two turrets will be of the elliptical balanced type, with sloping fronts. All the ships in this program will have water-tube boilers and twin quadruple engines. Bids for the three battleships authorized by the last Congress are now in the hands of the Navy Department. But these vessels, as called for, are mere duplicates of existing battleships of 11,500 tons displacement, 15 to 16-knot speed, and 16½-in. armor over vitals only. Under the present program the construction of these ships may be abandoned altogether, unless the bidders take advantage of the Secretary's appeal for greater speed. The $9,000,000 appropriated for these ships may thus apply to the present program, which will call for about $40,000,000 expenditure.

◆

BIDS FOR RAPID-FIRE PROJECTILES, in lots of 100,000 each, were opened at Ordnance Bureau on Aug. 23. About thirteen bidders appeared, and the prices offered were as follows:

6-pdrs. projectiles......99 cts. to $2.87; average about $1.35
3-pdrs. " ......75 cts. to 1.97; " " 80 cts.
1-pdr. " ......39 cts. to 97 cts.; " " 45 cts.

ARMY ENGINEERING WORK AT SANTIAGO is reported upon by Col. Edward Burr, Corps of Engineers, U. S. A., now of the 5th Army Corps, U. S. Volunteer Engineers. The Engineer Battalion under his command built a crib landing-pier at Siboney, 125 ft. long and extending to a depth of 9 ft. of water; this work was completed in 7 days. The battalion also made about six miles of road, under difficult conditions; replaced with a timber trestle a 60-ft. steel span of the Aguadores bridge, destroyed by the Spaniards, and repaired the La Cruz and Boniato bridges.

◆

TRANSMISSION LINES OF ALUMINUM will be used for carrying current from the Snoqualmie power plant to the cities of Seattle and Tacoma, Wash. There will be one main line 47 miles long to Tacoma, and about half way a branch of 12 miles to Seattle. Nos. 2 and 3 B. & S. aluminum wires will be used, containing 99.30% of aluminum, about 0.25% of iron and 0.30% of silicon, which will be alloyed with 1.50% of Lake copper. The total weight is estimated at 150,000 lbs. This is practically the first use of this material for long distance high tension lines.

THE NEW FRENCH CABLE which was formally opened on Aug. 17 is owned by the Compagnie Francaise des Cables Telegraphiques. It is the longest submarine cable yet laid, being 3,200 miles long. The copper conductors weigh 661 lbs. and the gutta-percha insulation 400 lbs. per nautical mile. Owing to the considerable length of this cable its transmission speed will be limited, with present apparatus, to 90 letters per minute, operating simplex, and 170 words with the duplex. The speed of the Anglo-American cables is about 2½ times that of the French cable.

◆

THE LARGEST INDUCTION MOTOR IN THE WORLD was recently completed at the works of Brown, Boveri & Co., Baden, Switzerland, and was described in the "Electrical World" of Aug. 25. The motor is a 1,000-brake-HP., 10-pole, 46-cycle, 2,500-volt machine, running at 544 revolutions per minute under full load. Complete it weighs 27 tons, and consists of the usual stationary part made in the form of a ring and mounted upon slide frames; the rotating part, with the shaft hollowed at one end for the connectors to the starting collector rings to pass out, and two heavy end-bearing plates, which can be moved along the tracks to expose the parts for examination or repair. The motor will be used to operate a large centrifugal pump to be installed in the municipal pumping plant of the city of Geneva.

◆

THE MOST SERIOUS RAILWAY ACCIDENT of the week occurred Aug. 28 on the Louisville & Nashville R. R., near Birmingham, Ala. The first section of the train carrying the 69th New York Volunteer Regiment jumped the track on a sharp curve and five cars were wrecked. One soldier was killed outright and two others died later, while five were seriously injured.

◆

A COLLISION AT SEA OCCURRED off the Banks of Newfoundland on Aug. 20 between the Thingvalla Line steamer "Norge" and the French fishing schooner "La Coquette," which resulted in the drowning of 16 of the schooner's crew. The collision occurred in a dense fog.

◆

FLOATING AN IRON TANK, 82 ft. diameter, to a new foundation was lately successfully performed at Dunkerque, France. This tank was nearly 33 ft. high and had a total weight of 140 metric tons. Newly imposed fire regulations required the removal of this tank a distance of about 131 ft. to a new beton foundation previously prepared. To avoid the cost of dismantling and again setting up the tank the owner constructed a dike about the two foundations; the tank was hermetically sealed and air was pumped in by a compressor at the refinery. Water was then pumped into the diked area from the neighboring canal, and the air pressure was regulated as the water rose about the tank. When the tank floated it was hauled by cables to its new site and as the compressed air was released the tank settled into its place, without injury or deformation.

TELEPHONE STATISTICS OF EUROPE show an increasing demand for telephone apparatus. The following table, prepared by the U. S. Consul at Chemnitz, Germany, shows the present number of lines and instruments:

Country.	Number of lines.	Instruments.	Inhabitants to each telephone.
Sweden	293	42,354	115
Switzerland	295	23,446	129
Luxemburg	57	1,356	160
Germany	534	131,577	397
Holland	31	7,900	615
Belgium	15	9,400	682
France	407	31,681	1,216
Austria	124	18,950	1,318
Spain	48	10,810	1,597
Hungary	36	8,458	2,168
Italy	54	11,815	2,629
Russia	53	16,050	6,988
Bulgaria	5	243	13,616
Roumania	6	337	16,042

◆

THE RAILWAY RETURNS for the United Kingdom, for the year ending Dec. 31, 1897, give the following official statistics of railways in operation at that date:

THE BLOCK SYSTEM is in operation on all but 3¾ miles of the New South Wales Government Railways, different methods of blocking being used, as follows:

	Miles.
Absolute block, double track	163¼
Electric train tablet, single track	563
Electric train staff, single track	415¼
Ordinary staff and ticket, single track	1,547¼
Freight lines, double track (no block)	3¾
Total	2,692½

◆

LOCOMOTIVES FOR RUSSIAN RAILWAYS are in brisk demand, and it is stated that an order for 550 locomotives of American types has been placed with the Putlov Works, at St. Petersburg. Fifty of these will be express and the remainder freight engines. The long distances to be run and the relatively slow speed of Russian service requires an exceptionally large number of locomotives. About the latter part of August 77 complete American locomotives were received for the Russo-Chinese roads; 50 of these came from the Baldwin Works and the rest from other American builders. A large number of freight engines are still required for the Siberian roads, together with railway supplies of all kinds, and large orders are expected to be placed in the United States about November next.

◆

THE TRANS-SIBERIAN EXPRESS TRAIN, which recently set out from St. Petersburg, is luxuriantly fitted up. The train includes five coaches; two for second and one for first-class travelers, and one dining and one baggage car. All the windows have plate-glass dust-screens; there is a bathroom, a buffet and a barber-shop; a library and a piano, and a stationary bicycle for exercise on the way. The train is lighted by electricity, and the kitchen is capable of providing a hot dinner for 60 people. There is no charge for the barber or for paper and envelopes; but the bath costs $1.00, and three hours' notice must be given. Starting at Moscow the traveler can now get to within about 200 miles of Irkutsk on the sixth day. This train, the second specially fitted and equipped for this service, started out with 40 passengers.

◆

THE RAILWAYS IN INDIA, on March 31, 1898, aggregated 25,454 miles open and sanctioned, of which 21,156 miles were open for traffic, leaving 4,298 miles under construction or authorized. This was a net increase of 766 miles over the length of line in operation in March, 1897. The grand total includes 13,707 miles of Indian standard gage (5 ft. 6 ins.), 10,374 miles of meter gage, and 447 miles of special gages, mostly 2 and 2½ ft. Only about 1,300 miles were double-track. The rolling stock equipment includes 4,205 locomotives, 12,500 cars in passenger service and 78,789 cars in freight service, the total number of vehicles being 94,720. Of this equipment 1,035 engines and 5,480 cars are fitted with the automatic vacuum brake, while 630 cars have the train pipes but no brake apparatus. About 2,600 passenger cars are fitted with the Pintsch compressed gas lighting apparatus, and this system of lighting is being rapidly extended. The average percentage of operating expenses to gross earnings was 47.8% (29.47 to 69.59%) on the standard gage; and 50.76% on the meter gage (33.66 to 92.71%). The average number of passengers and the average journey per passenger, were 189 passengers and 42 miles on the standard gage, and 215 passengers and 36¾ miles on the meter gage lines. The average haul per ton of freight was 160 and 124 miles respectively. The employees were 296,495 in number, of whom 4,793 were Europeans, 6,902 were East Indians, and 284,800 were natives. The flood damages were exceptionally severe, and an earthquake also caused a considerable amount of damage. The accident list shows 79 passengers and 230 employees killed; and 338 and 368 injured.

◆

THE NEW YORK STATE FOREST PRESERVE will be soon increased by the purchase of 50,000 acres of wild mountain forest land, in Ulster, Delaware and Sullivan counties. This will be added to the Catskill Mountain Forest Preserve, which already contains 56,212 acres in Ulster county. The new purchase includes some of the highest mountains of the Catskill Range, and covers the headwaters of the Delaware River.

Report of Railways in the United Kingdom for Year Ending Dec. 31, 1897.

	England and Wales.	Scotland.	Ireland.	United Kingdom, grand total.

Totals	£990,867,881	£155,483,074	£43,664,220	£1,190,015,175

THE POWER PLANT OF THE HUDSON RIVER POWER CO., AT MECHANICSVILLE, N. Y.

The large water power and electric plant recently completed at Mechanicsville, N. Y., owes its existence to Mr. R. N. King, President of the Stillwell-Bierce & Smith-Vaile Co., of Dayton, O. Early in 1897 Mr. King became interested in the Mechanicsville water power, and after securing assurances of patronage from several large users of power, he organized the Hudson River Power Transmission Co.

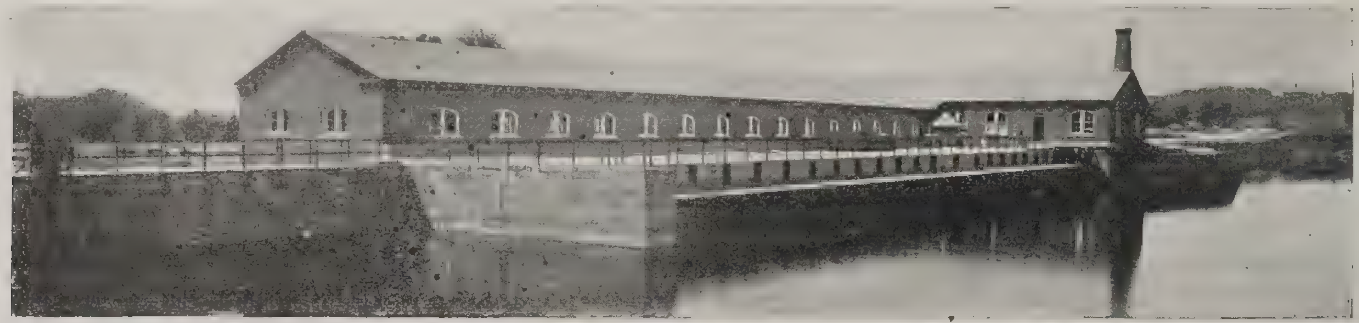

Fig. 4.—POWER HOUSE AND WESTERN DAM OF HUDSON RIVER POWER CO., MECHANICSVILLE, N. Y.; VIEW LOOKING DOWN STREAM.

The site selected is only 2 miles from Mechanicsville, 11 miles from Troy and 18 miles from Albany, in each of which towns there is a large market for power. Only 17 miles away is Schenectady, where the great works of the General Electric Co., occupying some 130 acres, were daily using tons of coal to operate steam engines, which in turn drove the dynamos necessary to supply current for operating the shop motors, testing apparatus, etc.

Naturally, as this company was to be one of the chief users of the power, their engineers were consulted regarding the electrical features of the installation. The hydraulic engineering features of the development were carried out from plans prepared by Mr. A. C. Rice, Chief Engineer of the Stillwell-Bierce & Smith-Vaile Co.

Location.—At the point chosen for the hydraulic development, the Hudson River is about 1,200 ft. wide, and is divided into two channels by Bluff Island, which stands about one-third the way across from the Western bank. The physical conditions make the location an ideal one for a dam and power house. During the greater part of the year the flow is sufficient to produce from 7,000 to 10,000 HP. In order to make the excavations for the dams and power house, coffer-dams were built across both channels. These were partly swept away by a heavy freshet, which caused considerable delay. It was also found that the rock excavated was unsuitable for concrete, of which the permanent dams were to be constructed, and it was necessary to build a special track and haul broken stone from a quarry near Schenectady.

The western channel of the river is closed by the power house, which extends from the shore out into the river about 250 ft., and by a concrete dam 26 ft. high above the bed of the river, 10 ft. wide on top, and 18 ft. wide at the base, extending from the end of the power house to Bluff Island. The upstream face of the dam is vertical and the downstream face has a batter. The top of this dam is at an elevation that the water will never reach, and it is not, therefore, designed to serve as an overfall, but the dam is provided with four arched waste gates 4 ft. wide and 6 ft. 9 ins. high, operated in the same manner as those in the main dam.

The main dam, Fig. 1, extends across the eastern channel of the river, and is also of concrete throughout. This dam is 16 ft. high above the river bed, 8 ft. thick immediately below the crest, and 16 ft. thick through the base. The dam is set between massive abutments anchored to the rock sides of the river bank and island. The upstream face is vertical, the downstream face is curved and provided with a horizontal apron 14 ft. wide, designed to give a horizontal direction to the fall, and prevent wash or scour at the toe of the dam.

This dam springs from two abutments, the eastern is 20 ft. long, 26 ft. high above river bottom, 16 ft. thick at the top, and 34 ft. wide at the base, while the western abutment is 100 ft. long, the other dimensions being similar to those of the eastern abutment. The length of the spillway between abutments, Fig. 2, is 800 ft. In the western abutment are 12 arched openings for waste gates. Each of these gates is 4 ft. wide and 6 ft. high, and is opened and closed by a heavy iron hoist operated by rack and pinion. The eastern dam is practically a solid rock wall capable of safely resisting any flood. It was severely tested in the spring of 1898, when an unusually large freshet came against it, yet, notwithstanding the fact that the dam was green, it was in no way injured.

To prevent any floating rubbish, ice, or logs reaching the racks or choking the waste gates, a floating wooden boom stretches from the western end of the spillway diagonally for a distance of 400 ft. to the edge of the normal river bank, and then for a distance of 1,000 ft. to the main embankment of the Mechanicsville highway. This boom is anchored to a line of stone-filled cribs.

From the west end of the power house to the Mechanicsville highway a broad embankment has been built to serve as a roadway, and cut off the flow along the river bank in high water. It was built of earth and slate rock with a concrete core, and is shown in section by Fig. 3.

Power House.—The power house, Fig. 4, lies between the west bank and the short concrete dam, nearly filling the space between the island and the west bank of the river, and is practically a continuation of the dam. It is of concrete, with the exception of the upper walls, and its construction is of the most substantial character. The foundations are carried down to the bedrock, and the house is carried on heavy steel box girders resting upon steel I-beam columns. The latter are imbedded in concrete walls carrying arches which form the floor of the generator room and the floor on which the wheel flumes rest. The walls form a separate and distinct tail-race 22 ft. wide for each set of turbines, from which the water may be shut out at will.

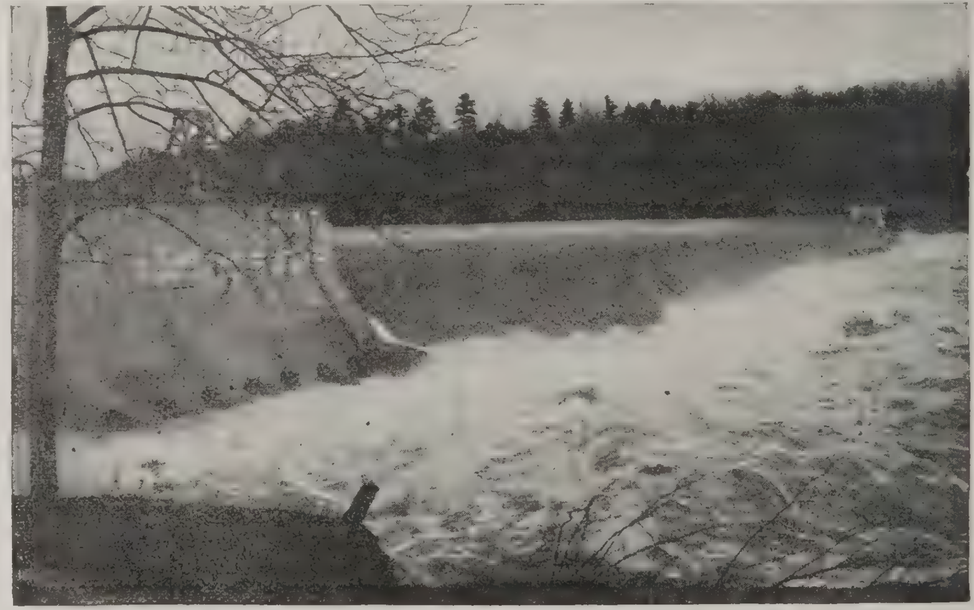

Fig. 2.—DOWN STREAM SIDE OF MAIN DAM SHOWING WASTE WATER PASSING OVER.

The house is divided into two parts by a thick head wall, Fig. 5. The upstream part contains wheel chambers for 7 1,000-HP. wheels, of which 5 only are at present occupied. The downstream portion contains wheel governors, and the electrical apparatus. The length of the power house proper is 257 ft. 6 ins.; the width of the dynamo room between head wall and south wall 34 ft., and the width of the wheel chamber portion 32 ft. 6 ins. The total width of the power house is 60 ft 6 ins. At the western end an L extension runs upstream 87 ft. 5 ins. long and 44 ft. 10 ins. wide. A retaining wall runs down stream from the power house along the western bank a distance of 50 ft.

Arched chambers are provided for 7 main wheels and two exciter wheels. Each main chamber is 32 ft. 6 ins. long, 22 ft. wide and 17 ft. 5 ins. high, and is provided with two 6-ft. manholes. Each exciter wheel chamber is 32 ft. 6 ins. long, 17 ft. 5 ins. high and 10 ft. wide. The head wall of the chambers is 6 ft. thick, the wall on the upstream and both sides 3 ft. thick. In the head wall of each main chamber is set a heavy cast-iron cover through which the turbine shaft passes in a watertight packing box, carrying the ring oil bearing for the shaft. The saving in space effected by the new arrangement of housing and coupling together of the turbines, patented by the Stillwell-Bierce & Smith-Vaile Co., has diminished considerably the size of the power house. A 20-ton crane from the works of Pawling & Harnishfeger, Milwaukee, runs the entire length of the dynamo room.

In front of the wheel chambers and running the entire length of the power house, is a trash rack of steel bars supported on a framework of steel channel and I-beams. This rack effectually prevents the access to the wheels of any rubbish or floating material that may escape the boom.

Water Main Wheels.—There are ten pairs of 42-in. horizontal Victor turbines, built by the Stillwell-Bierce & Smith-Vaile Co., of Dayton, O. Each main turbine consists of two pairs of wheels, which, at the normal speed of 114 revolutions, and the obtainable head of 18 ft., is rated at 250 HP. The total power of each set of turbines is, therefore, 1,000 HP. At present 5 units are in position, the two additional turbines will be installed later. The turbines for the exciters consist of three 18-in. Victor cylinder gate wheels, having, at 259 revolutions per minute a total of 300 HP.

Two draft tubes lead from each main turbine, the forward tube descending straight into the tail-race beneath the power house, the rear or up-stream tube curving and flaring downward and outward. Each tube is 9 ft. 6 ins. in diameter at the bottom. Two draft tubes are also allotted to each set of exciter wheels.

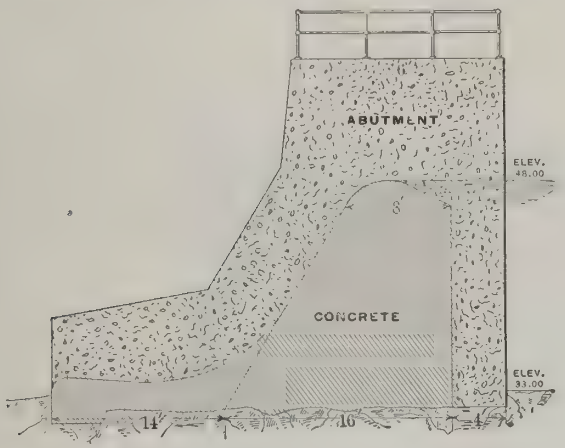

Fig. 1.—Section of Main Concrete Dam Showing Overfall and Section of Abutment.

The speed of each set of main wheels is regulated by a Geisler electro-mechanical governor, mounted on a platform directly over the turbine shaft, and between the head wall and the generator. The use of electricity renders the mechanism of this governor extremely sensitive and effective, and the gates can be entirely opened or shut in 6 seconds should the full current be thrown on or off. The driving pulley is replaced by a rawhide pinion, giving a rigid connection between the governor and the wheel. The governor wheel speed may be increased to shut off or throw on in less than 6 seconds, if necessary. This type of governor is now in use in many of the most important electric power transmissions in this country, including those of Columbia, S. C.; Pulzer, N. C.; Lachine, Que.; West Kootenay, B. C., and Montmorency, Que. The exciter wheel gates are controlled by improved "Snow" governors. They are especially adapted to the regulation of water wheels driving exciters, and are provided with adjustable stops, which limit the hoisting action on the gate as soon as the gate is fully open.

Generators.—These are placed in a large well-lighted room, Fig. 6, 34 × 255 ft., and 30 ft. 5 ins. high in the clear, from floor to roof truss. The ultimate generator capacity of the station is 7,000 HP., in 7 generators, each of 750 K-W. capacity, although only 5 have been installed and are now running. These are uni-tooth, three-phase, 40-pole 750-K-W., 114-revolution alternating current machines, having revolving fields and stationary armatures. They are wound to deliver to the transmission lines, 36 amperes at a periodicity of 38 cycles and a pressure of 12,000 volts. They are arranged for operation in parallel at constant voltage. By using the revolving field type of generator it was possible to secure this high pressure directly from the machine without the use of step-up transformers. As the current is to drive synchronous and induction motors, to operate lights and to be converted into direct current through rotary converters, a frequency of about 40 cycles was selected as most suitable.

The alternators are similar in their main characteristics to those successfully used in the Lachine Rapids plant at Montreal; that is, the armature frame or ring is of the box type, 15 ft. 4 ins. in diameter and 36 ins. wide. It is bolted to a base 18 ft. 2 ins. long by 10 ft. wide, along which it may be moved parallel with the shaft, in order that the revolving field spider and poles may be uncovered should occasion arise. The field ring is bolted to the spokes of the spider and carries 40 poles each, securely fastened by two bolts to the ring. The whole revolves on a shaft 15 ins. in diameter, provided with a rigid bolt-coupling on the turbine side, which connects with the turbine shaft. The dynamo shaft is also extended at the other end for coupling to a vertical steam engine in case of necessity.

The following reasons for selecting this type of alternator have been given by Mr. C. P. Steinmetz of the General Electric Co.:

> In addition to the advantage which the stationary armature type has over the stationary field type in allowing a high transmission voltage to be taken directly from the armatures, it allows of a fairly low saturation of the magnetic circuit giving an almost straight saturation curve. This is preferable in power transmission, since a considerable increase in the voltage may be obtained if needed to cover excessive drop in the lines due to heavy loads, and the voltage may be maintained even if the speed remains low.

The exciters for magnetizing the fields of the generators are placed one on each side of the stairway leading to the switchboard gallery. They are 6-pole, 100-K-W., 125-volt standard General Electric machines with ribbed field frame and iron-clad armatures.

Switchboard.—The switchboard is erected on a gallery on the north wall of the dynamo room, and is built up of nine polished blue Vermont marble panels, each 7 ft. 6 ins. × 3 ft. and 2 ins. thick. Five are used for the generators and two for the feeders; one is the total output panel and the last is for the control of the exciters. The generator panels occupy the left side of the board, and space is left for two additional panels. The feeder panels are on the right side; the total output panel is between these and the generator panels.

Each generator panel is equipped with one inclined coil alternating ammeter reading to 75 amperes for the armature, and one direct current ammeter reading to 150 amperes for the field. Above each of these is a pilot lamp and a synchronizing lamp. Beneath the two ammeters is an inclined coil voltmeter reading to 15,000 volts, and beneath this instrument are three single-blade, double-throw, quick-break, high-tension switches, which are each mounted upon pyramids of corrugated hard rubber. Similar pyramids intervene at the back of the board between the bus-bars and the boards. The corrugations give a total distance of about 8 ins. of surface between the metal clips and hinge and the surface of the marble on each side. As these switches are to break current of 12,000 volts they are tested to break without difficulty currents of 21,000 volts. For safety the switches are made without handles, an eye being made in the end of each blade, into which a hook at the end of a stick may be inserted and the switch opened by the attendant from a safe distance. Further, to prevent any dangerous arcing from blade to blade, marble barriers 1¼ ins. thick, 3 ins. long and 12 ins. wide, from the face of the board are erected between the blades.

On the left hand side of each generator panel sub-base are two 100-ampere, double-pole, double-throw, carbon-break switches—one the field switch, the other the lighting switch. On the back of the panels are the high tension fuse blocks.

These fuse blocks, designed for 20,000 volts, are of the snap break expulsion type. They are mounted on pyramids of corrugated hard rubber, which contain copper spring contact clips between which the two copper blades on the block enter, connecting the fuse block to the line. The aluminum fuse is held tightly between two arms which are movable around a pivot and may be pulled apart by two strong spiral springs encircling this pivot. As soon as an increase of current in the line melts the fuse, its two halves are instantly pulled apart, thus preventing the formation of an arc between the two halves. The melting of the fuse can only occur in a small chamber protected by wooden blocks. The whole fuse block is inserted in the line by simply pushing the two blade-like copper contacts between the clip contacts, which are connected by solid copper rods to the bus-bars. The field rheostats are hung beneath the gallery, and are operated by hand wheels conveniently placed on the gallery.

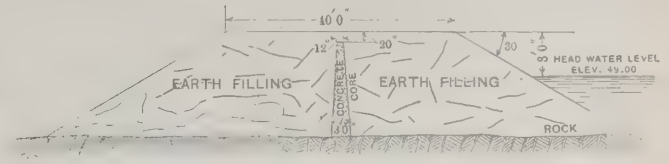

Fig. 3.—Section of Earth Embankment Forming Roadway.

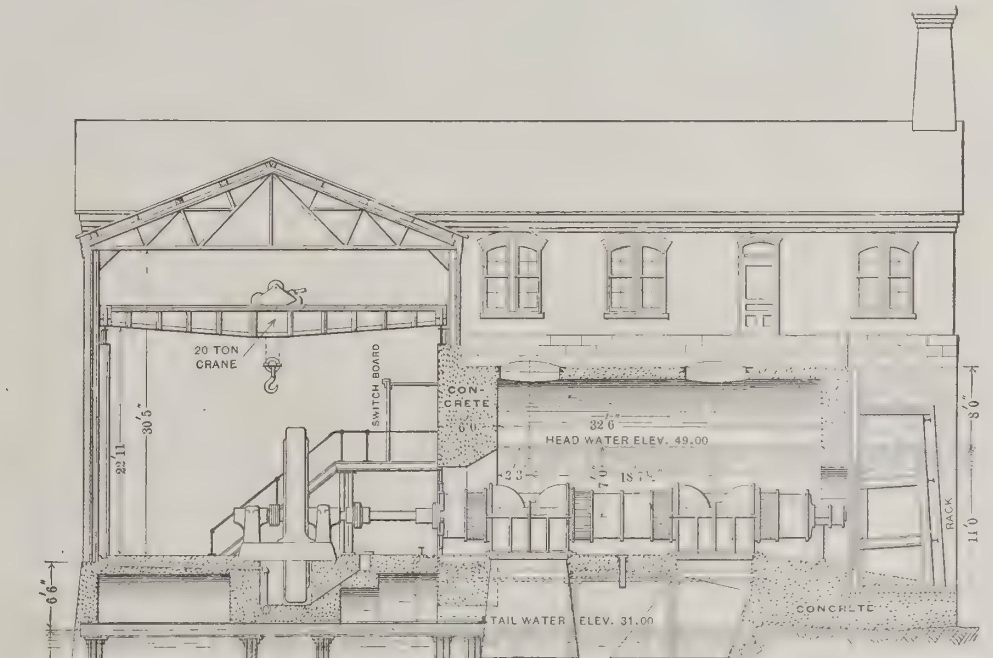

Fig. 5.—SECTION OF POWER HOUSE SHOWING TURBINES, DRAFT TUBES, GENERATORS, ETC.

The exciter panel controlling the two direct current exciters carries two pilot lamps, two circular dial ammeters, each reading to 1,000 amperes, one volt-meter reading to 150 volts, one four-point pressure switch, one synchronizing switch, two 880-ampere, triple-blade, double-throw, equalizer switches and two packed card rheostats placed at the rear.

The two feeder panels are alike in every respect, and each outgoing line is provided with an independent ammeter reading to 150 amperes and a quick-break, double-throw, high-tension switch similar to those on the generator panels, and similarly mounted on the board. Mounted also on corrugated hard rubber pyramids are the six circuit breakers or automatic plunger switches, which are a special form of quick-break, non-arcing switches. A rocker arm controls the three switches for each set of bus-bars, so that they may be all released at once. On the upper part of each feeder panel at the back is a current transformer for each outgoing line, two recording single-phase watt meters, each reading to 25 amperes and 12,000 volts and two potential transformers. On the front of the output panel are 2 Thomson recording watt meters for balanced three-phase circuits, each reading to 300 amperes and 12,000 volts and 12 triple-pole, single-throw 100 ampere switches with fuses for the lighting circuits. On the back are 4 potential and 2 current transformers.

The lightning arresters are of the G. E. short gap type, similar to those installed on nearly all of the important long distance transmission lines in this country which have proved most satisfactory. It will be remembered that this arrester allows the passage of any high potential discharge, but effectually prevents the line current from following and maintaining an arc. The action of the arrester is dependent upon the cooling effect of two metal cylinders, 2 ins. in diameter and 2 ins long, placed 1-32d-in. apart, aided by the reversal of the alternating current and the introduction of a low non-inductive resistance, composed of graphite rods. The line is protected by double-pole 2,000-volt arresters connected 6 in series to give the necessary number of spark gaps. There are 3 sets of these; one at Mechanicsville, grouped around the first transmission pole in a small house 15 ft. square, one set where the overhead pole line connects with the underground cable and the third at the General Electric works.

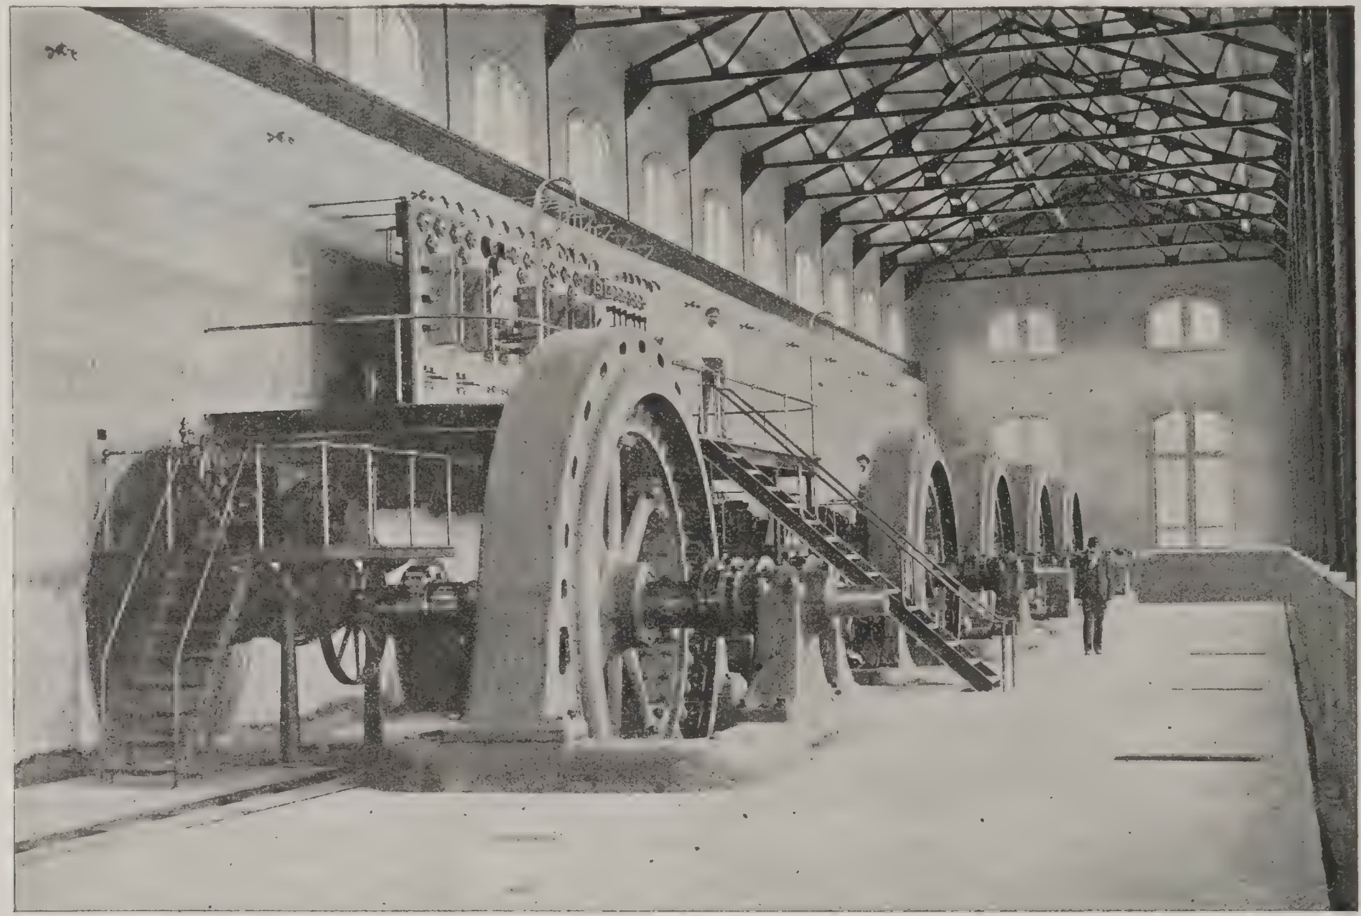

Fig. 6.—INTERIOR OF DYNAMO ROOM SHOWING FIVE THREE-PHASE GENERATORS, SWITCHBOARD, ETC.
General Electric Co., Schenectady, N. Y., Builders.

The lead covered cables from the generators are taken out at the base of the machine, and are laid in ducts in the floor. The cables rise on a frame from the floor duct to the switchboard on the gallery, from the back of which the line wires rise to supports bolted to the I-beam on the north wall, which supports one of the crane runways, and thence around the building part way and out.

The transmission line from Mechanicsville to Schenectady is the only one in place at present. It consists of three No. 000 B. & S. bare wire, this large gage being employed in order to give the line as high self-induction as possible. The insertion of self-induction in transmission lines is a departure from earlier practice. In cases where synchronizing apparatus is used, self-induction is now considered necessary, and is artificially brought into the line in the shape of reactive coils in cases where the natural self-induction is too small. The circuits are carried on poles, 30 to 60 ft. long, and all 8 ins. in diameter at the top. Each pole carries one cross arm, on one side of which are two porcelain insulators of the triple petticoated type, a third being on the other side. For lightning protection a barbed wire, frequently grounded, runs along the tops of the poles.

The line takes a westerly direction to East Glenville, and then due south to Schenectady. At the end of the Glenville bridge over the Mohawk, the town limits, it is carried down to the ground and connected to three cables of No. 1 B. & S. stranded copper wire, insulated by one-quarter-inch rubber and 3-32-in. lead sheets, which are laid in terra cotta conduits. These cables run 1,700 ft. along Washington Ave., rise to poles again, pass through Rotterdam St. to the Erie Canal, and along the canal to a point directly opposite the General Electric Company's power station. They then cross the canal and enter the works.

The introduction of this transmitted electrical power into this factory will work a considerable change. At present all the machinery is driven by electric motors, while the testing department demands an independent supply of current for the work it carries on. There are at present, therefore, two distinct generating plants. The 550-volt motors in the testing department are supplied from an engine driven multipolar generator of 500 K-W. capacity, while a smaller engine drives a number of exciters, which allow of independent control of the excitation of all machines is this department. The factory is operated by a number of 250-volt motors running on the same circuit as the factory lights. These motors will not be changed, and the steam plant which supplies them will be retained as a reserve in case the power from Mechanicsville should fail. The electric power plant superseding the present steam plant at the works will, therefore, consist of two synchronous motors. one of 500 K-W., the other of 100-K-W., and three 400-K-W. rotary converters —the synchronous motors for the testing department, the converters to supply current to the factory motors.

The large engine driving the 500-K-W. multipolar generator is superseded by the 500-K-W. synchronous motors. This is a 12-pole, 400-revolution machine of the revolving field type, wound directly for 10,000 volts. The small engine driving the exciters is replaced by the 100-K-W. synchronous motor—an 8-pole, 600-R. P. M. revolving field machine similarly wound. This disposition renders the testing department independent of everything but the speed of the Mechanicsville generators which will be kept as nearly constant as possible.

The three rotaries supplying 250-volt current to the factory motors are 10-pole, 400-K-W., 480-R. P. M. machines, having two commutators and two sets of collector rings, connected to independent windings on the armature. They receive the three-phase current from independent secondary coils of the same set of air blast transformers. When connected in multiple they furnish current at normal pressure of 250 volts, but as they may be called upon to furnish current to the testing department, in case the demand exceeds the supply from the synchronous motor driven machine, they may be connected in series to give 500-volt current, operating in parallel with the railway generator, driven by the synchronous motor in the testing department. Synchronous motors were selected in preference to induction motors on account of, first, their more constant speed and greater efficiency; second, because they do not produce lagging currents, but the phase displacement and power factors may be controlled as desired by means of controlling the field excitation. It is also a fact that synchronous motors of the revolving field type and of good design are self-starting even under heavy load, and will easily carry two or three times full load without falling out of step for a time, which is limited only by the heating of the motor.

The entire construction of the dams, power house and lines has been carried out by the National Contracting Company, of which G. M. Furman is general manager. Mr. R. A. Mathews, superintendent, and J. A. Leonard, constructing engineer The electrical equipment is furnished by the General Electric Company and the hydraulic equipment by the Stillwell-Bierce & Smith-Vaile Co., of Dayton, O., to which company was confided the entire development contract. It took the Hudson

River in its natural condition and turned over to the operating company the plant in running order.

The officers of the Hudson River Power Transmission Company are: General Edmund Hayes, of Buffalo, N. Y., president; R. N. King, president of Stillwell-Bierce & Smith-Vaile Co., of Dayton, O., vice-president; G. M. Furman, Newark, N. J., treasurer; Mr. E. J. Richards, Boston, Mass., superintendent; J. S. O'Shea, manager.

Our acknowledgments are due to the General Electric Co. for the cuts and information made use of in the preparation of this article.

SEWAGE PURIFICATION BY INTERMITTENT FILTRATION AT CENTRAL FALLS, R. I.

The city of Central Falls, R. I., has an estimated population of 16,000, compactly located on an area of only 1.3 square miles. A public water supply was introduced in a portion of this territory in 1879, the city having been formed only a few years ago. Sewers were first put in operation in 1889. The sewerage system is divided into two districts. The larger of these districts was the first to be provided with sewers, the contents of which are discharged into the Blackstone River without treatment. At the close of 1897 this district had about 6¼ miles of sewers, and 374 house connections.

In 1893, a report on a sewerage system for the second, or western district, was made by Mr. S. M. Gray, M. Am. Soc. C. E., of Providence. Mr. Gray recommended the construction of both sanitary and storm sewers, but on the separate plan, the sewage proper to be treated by chemical precipitation. In 1894, Mr. L. C. Heywood, the engineer for the town of Lincoln, from which the city of Central Falls was afterwards set off, recommended combined sewers, with disposal by intermittent filtration, advising the present location for filter beds. The sewers were begun under Mr. Heywood, who died in January, 1895, and was succeeded by Mr. Wm. Faitoute Keene, Assoc. M. Am. Soc. C. E., the present city engineer, before more was done about the filter beds than to buy the land. Mr. Keene designed the settling basins and filter beds now in use and they were also built under his direction as city engineer. The effluent from the beds, together with the storm overflow, discharges into the Moshassuck River, which empties into the head of Narragansett Bay.

About Sept. 1, 1896, the sewers and filter beds were put in use. At the close of 1897 there were about 1½ miles of sewers in the district, including the outlet, with 87 house connections, serving 101 houses. On June 11, 1898, the number of connections had increased to 98 and these gave service to 112 houses. Each house in this district had an average of about ten inhabitants by the census of 1895.

The lower portion of the outlet is a 60 × 90-in. brick sewer, of horseshoe shape, 863 ft. in length, with a grade of 0.1 ft. in 100 ft. There has been trouble with sand in the invert of this sewer, which has reached a depth of 1 ft. between periods of removal. At the lower end of the outlet sewer there is an automatic device by means of which the entire flow may be shut off from the beds during heavy rains. This device consists of a brick well, 5 ft. square inside, with a 12-inlet from the brick sewer, and two 12-in. outlets, one of which is the overflow. The regulating is done by a float connected with a shut-off gate on the trestle pipe line, mentioned below, so arranged that when the float reaches a certain height the gate closes, and the sewage runs through to the overflow pipe.

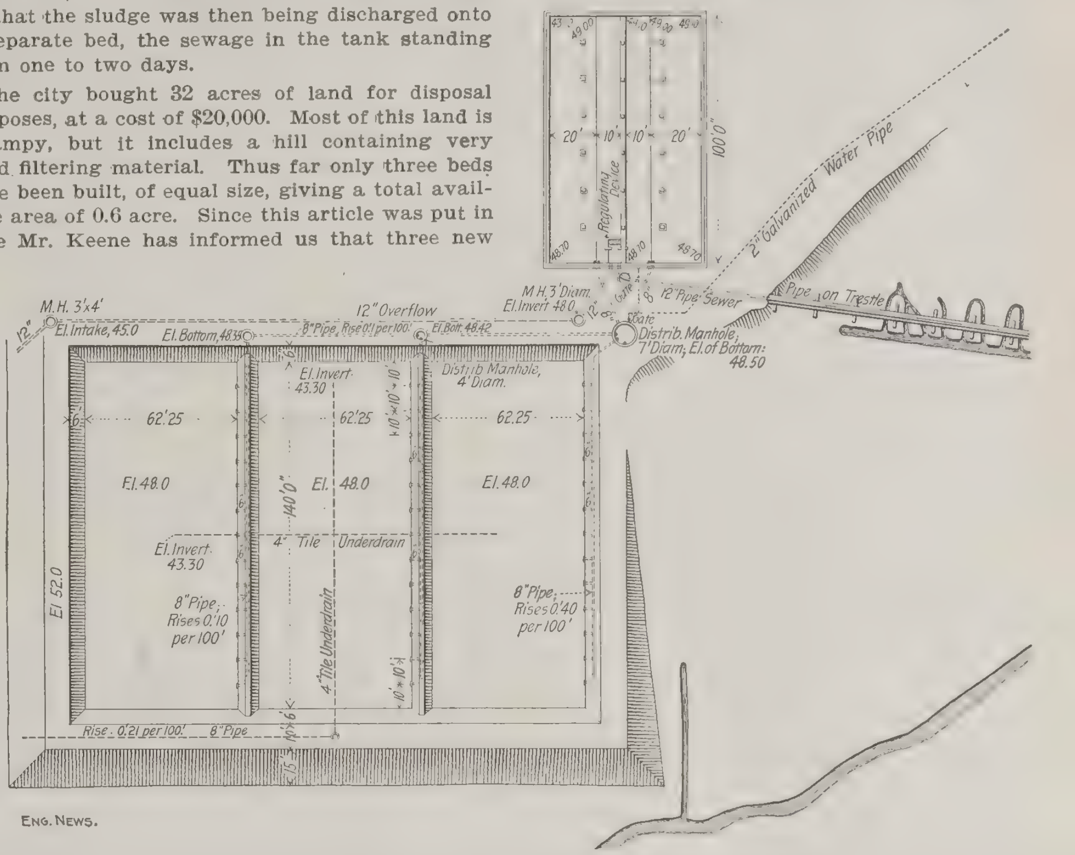
The sewage is conveyed from the end of the brick outlet across the swamp to the settling tanks and beds through a 12-in. Akron pipe on a timber trestle. The pipe is in 2-ft. lengths, with yarn and cement joints. Settlement of the trestle was expected and provided for, but the settlement has been greater than was expected. The trestle was built only for temporary use.

Two settling tanks are provided, near the beds, as shown by the plan. This plan gives the principal dimensions of the tanks, beds and accessories, with the exception of the available depth of the tanks, which is 40 ins.

Only one of the two settling tanks is used at present. Each tank has an available capacity, for purposes of sedimentation, of 70,000 gallons. Both tanks are floored over and have a roof forming a one-story building. Part of the enclosed space is used for a gage room and office, and the remainder for the storage of sprinkling wagons and other city property. Beneath the gage room is a small receiving and regulating tank for each of the settling tanks.

When the plant was visited in November, 1897, by a member of the editorial staff of this journal, the practice was to discharge the one tank in use when the sewage in it had accumulated to a depth of 25 ins., or about once in two or three days. The sludge was then being turned onto the filter beds, but in June, 1898, Mr. Keene informed us that the sludge was then being discharged onto a separate bed, the sewage in the tank standing from one to two days.

The city bought 32 acres of land for disposal purposes, at a cost of $20,000. Most of this land is swampy, but it includes a hill containing very good filtering material. Thus far only three beds have been built, of equal size, giving a total available area of 0.6 acre. Since this article was put in type Mr. Keene has informed us that three new beds are under construction, each with an area of 0.2 acre. No chemical analyses of the sand have ever been made.



Eng. News.

PLAN OF SETTLING TANKS AND FILTER BEDS FOR THE SEWAGE DISPOSAL WORKS OF CENTRAL FALLS, R. I.

Wm. Faitoute Keene, City Engineer.

The total amount of sewage treated during 1897 was 4,042,721 gallons, or an average of about 11,700 gallons a day. This, on an area of 0.6 acre, is equal to about 19,500 gallons per acre per day. Mr. Keene places the flow of sewage in June, 1898, at about 20,000 gallons a day, and states that the sewage is very strong, as no ground water enters the sewers. He says that in consideration of the fact that authorities allow one acre for each 1,000 inhabitants, and their 0.6 acre is treating the sewage from 1,120 people, he does not think the rate is a low one. According to his figures the flow is now nearly double the average for the year 1897, being at the rate of about 33,000 gallons per acre per day.

One man is stationed at the beds for the purpose of caring for them and recording the amount of sewage treated, together with the temperature of both air and sewage. In November, 1897, the beds were found to be nicely graded and everything appeared to be in good condition. The sand is light in color, giving the beds a unique appearance. The embankments are of sand and have not yet been covered with grass. The sand was handled for about 12 cts. per cu. yd. The total cost of the plant, including the trestle across the swamp, but not including land, has been about $10,000 thus far. The unit cost will be diminished as the disposal works are extended. We are indebted to Mr. Keene for courtesies extended during the visit of our representative to the plant, and for drawings, reports and notes furnished to us.

THE FIRST RAILWAY IN KOREA.

The American victories in the Philippine Islands will undoubtedly have an important result in calling attention to American commercial movements in the Far East and in promoting our foreign commercial interests. In a recent issue we described some of the work done by Americans in the Hawaiian Islands, and we are now able to present some interesting particulars of the railway which is being built in the little empire of Korea by the Seoul & Chemulpo Ry. Co., under a concession granted in 1893 to Mr. James R. Morse, president of the American Trading Co., of New York city. Until within the past few years, Korea has been probably the most isolated and self-dependent state in the world, having few relations with other countries and being practically devoid of all the improvements of modern civilization, but the advent of the railway will undoubtedly lead to the opening up of the country for foreign trade.

The railway will extend from the port of Chemulpo to the capital city of Seoul, a distance of about 25 miles, but it will not be completed until early in 1899. Delays in the construction have been caused by the owners recently deciding upon extensive changes in reducing the maximum grade from 2% to 1%, and decreasing the mimimum curvature from 8° to 6°. Other delays have occurred in reclaiming from the sea all the land necessary for extensive terminals at Chemulpo, necessitating the construction of a strong sea-wall and much filling in on the foreshore. The line will pass through a country composed of valleys and small hills, the highest and lowest elevations or summits being 146 ft. and 35 ft. For two-thirds of its length the line will pass through rice fields. The traffic will consist largely of rice, beans, coal and general freight. The gage is 4 ft. 8½ ins., which is the same as that of the Chinese railways, except that the new Manchurian Railway will be of the Russian standard gage of 5 ft., being an extension of the Trans-Siberian Ry. It is expected that eventually a line will be built northward from Seoul to connect with the Manchurian line, or with the North China Ry. from Pekin.

There are no very important engineering works, with the exception of a steel truss bridge 2,063 ft. long, having ten equal spans, which crosses the Han River four miles south of Seoul. This bridge was built by the Universal Construction Co., of Chicago, (Illinois Steel Co.). Timber trestles are used for other crossings, and it is probable that these will be replaced by steel structures in the near future. There are no tunnels, and the materials encountered in excavation are mainly granite, decomposed granite, clay and loam. The American-Oriental Construction Co. has the contract for construction, and most of the work is done by small sub-contracts; Korean, Japanese and Chinese laborers being employed.

The track is laid with 56-lb. rails, rolled by the Illinois Steel Co., the joints being spliced by soft steel angle-bars with four bolts. The ties are of Korean and Japanese timber, similar to pine of moderate quality, and there are 15 ties to a rail. The ballast is of broken stone.

The equipment includes four locomotives, 20 passenger cars and 100 freight cars. The locomotives are tank engines of the mogul type, built by the Brooks Locomotive Works, of Dunkirk, N. Y., and one of these was illustrated in our issue or Feb. 24. The cars are of the American type, and most of them were made by the Jackson & Sharp Co., of Wilmington, Del.

For the information respecting this railway we are indebted to Mr. D. H. Collbran, of the American-Oriental Construction Co. (formerly of the Colorado Midland Ry.), who is in charge of the company's interest in Korea. Mr. Collbran has the concession for an electric railway at Seoul, and five miles of 25-lb. rails for this line have been shipped from this country. He is also negotiating for a concession for the electric lighting of that city.

THE DAVIS AVENUE CANTILEVER HIGHWAY BRIDGE, ALLEGHENY CITY, PA.

We illustrate herewith the strain sheet and some of the more important details of a cantilever highway bridge now being built to span a deep ravine which intercepts the approach to Riverview Park, in the city of Allegheny, Pa. The park has an area of about 250 acres, and is being rapidly improved by drives and footpaths. It is situated in the northern part of the city, and at present is reached by only two main streets from the center of the city. The bridge illustrated is designed to give access to the western portion of the park from all that portion of the city lying to the north and west. A road along the bottom of the ravine, which the bridge crosses, also gives access to the western end of the park. The contract for building the bridge has been let to Mr. Gustave Kaufman, M. Am. Soc. C. E., of Pittsburg, Pa., for $25,754.

The illustrations explain quite fully the principal structural features of the bridge, and only a few of the minor details need to be mentioned here. Fig. 1 shows the strains and composition of the different truss members; Fig. 2, a half transverse section disclosing the latticed floor beams and stringer and floor construction, and Fig. 3, details of the abutment anchorages. As will be seen, the roadway is carried by seven lines of intermediate stringers and two guard rail stringers, and each sidewalk by one intermediate stringer and an outside stringer. The intermediate roadway stringers are rolled I-beams, but the sidewalk and guard rail stringers are made up of plates and angles. These stringers rest on top of the floor beams and are riveted to them. On top of the stringers come buckle-plates ¼-in. thick arched 2½ ins., which are riveted to the top flanges of the I-beams with rivets to be spaced not more than 5 ins. apart. These buckle plates sustain the floor covering of concrete and asphalt paving. The specifications call for a thickness of 2½ ins. of concrete over the highest part of the buckle plates, the concrete to consist of Portland cement, clean, sharp sand, and 1½ in. broken stone. The paving of asphalt will be 1½ ins. thick.

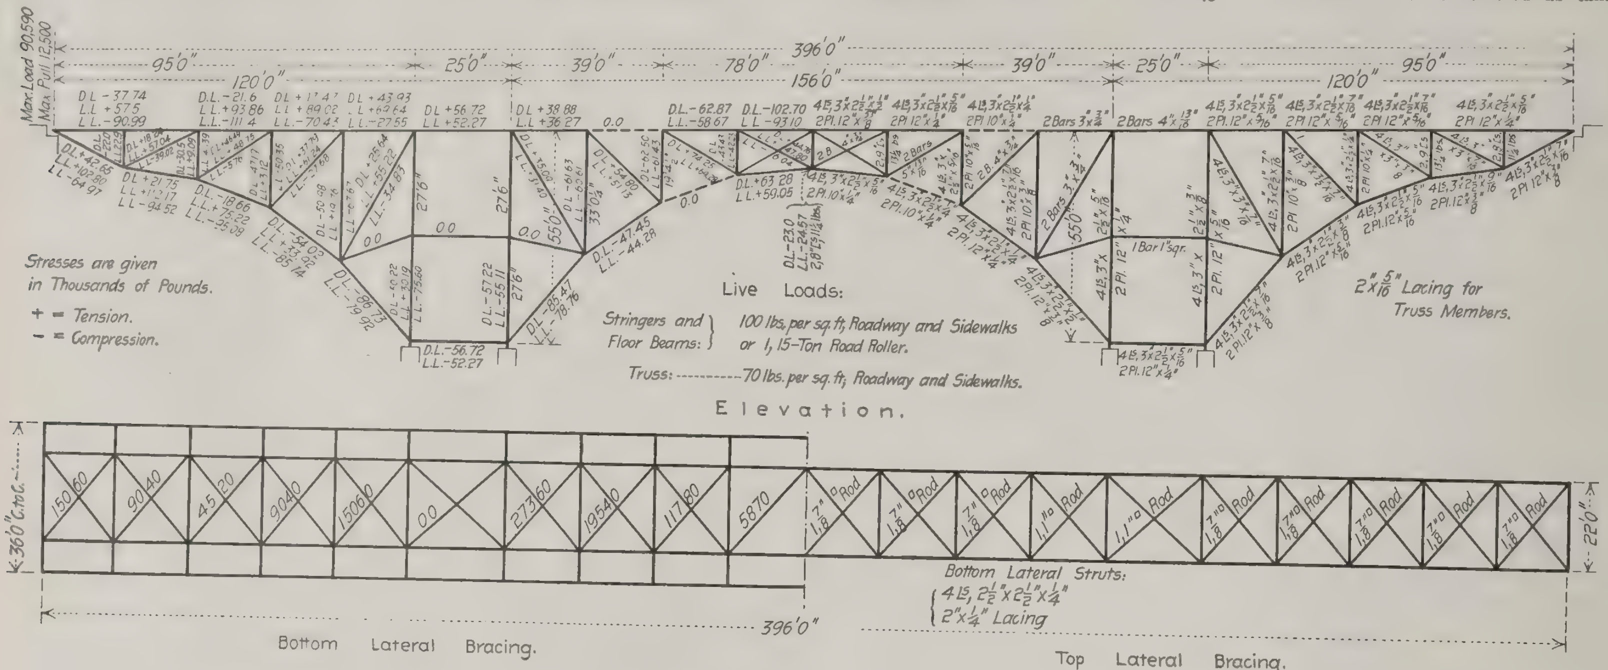


FIG. 1.—STRAIN SHEET AND MAKE UP DIAGRAM, DAVIS AVE. CANTILEVER HIGHWAY BRIDGE, ALLEGHENY CITY, PA.
D. L. Fulton, Superintendent Highways and Sewers, Allegheny City, Pa.
Gustave Kaufman M. Am. Soc. C. E., Pittsburg, Pa., Contractor.

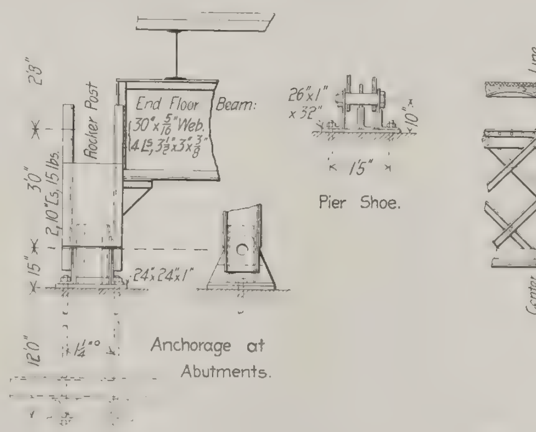

Fig. 3.—Abutment Anchorages, Davis Ave. Bridge.

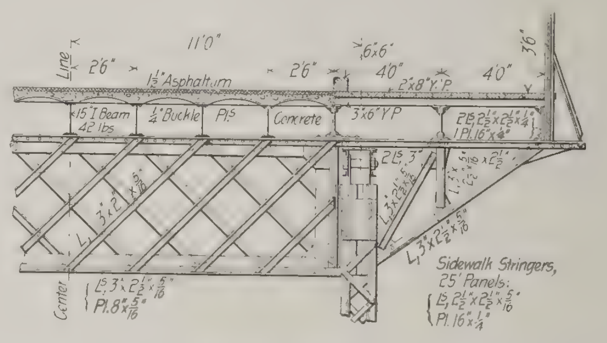

Fig. 2.—Transverse Section of Davis Ave. Bridge, Showing Sidewalk and Floor Construction.

All parts of the bridge will be of steel except the lateral rods and welded parts, which will be of wrought iron. The various members were designed so that the following unit strains would not be exceded:

Bearing on shop rivets	15,000 lbs.
" " field "	12,000 "
Shearing on shop rivets and pins	7,500 "
" " field "	6,000 "
" " pin plates	6,000 "
Binding on pins	20,000 "
Bearing " "	18,000 "

For wind stresses an addition of 25% was made to the above unit strains. In regard to riveted work the specifications contained the following requirements:

> Rivets will not be less than ¾-in. in diameter. Direct tension on rivet heads shall be avoided. The pitch of rivets shall in no case exceed 6 ins., nor be less than three diameters of the rivet. At the ends of compression members the pitch shall be four rivet diameters for a length equal to twice the total width of member. The effective diameter of a driven rivet shall be assumed the same as its diameter before driving. Where practicable, the distance from edge of any piece to center of rivet shall be two diameters of rivet. The shearing or bearing value of countersunk rivets in plate ⅜ to ⅝-in. thick will be taken as one-half the full value. Countersunk rivets in plates less than ⅜-in. thick will not be considered as taking any of the stress, and in plates ⅝-in. thick or over the regular value shall be used. In deducting rivet holes to obtain the net section in tension the rivet hole will be taken with a diameter of ⅛-in. larger than the undriven rivet for rivets with full heads and ¼-in. larger for countersunk rivets. All rivet holes shall be punched 1-16-in. larger in diameter than the diameter of rivet to be used.

The requirements for workmanship called for first-class methods and finish, but present nothing unusual. In regard to the material, the specifications state that,

> All steel must be uniform in quality and must be made by the open-hearth process. It shall contain not more than 0.08% phosphorous in the finished product, and shall have an ultimate tensile strength of not less than 56,000 lbs. nor more than 64,000 lbs. per sq. in.; an elastic limit of not less than 30,000 lbs. per sq. in.; an elongation in 8 ins. of not less than 25%, and shall show a reduction in area at the point of fracture of not less than 45%. Steel for rivets shall have an ultimate strength of from 48,000 lbs. to 58,000 lbs. per sq. in.; an elastic limit of not less than one-half the ultimate strength; an elongation of 26% in 8 ins., and a reduction of area of not less than 50% at the point of fracture.

The usual bending, hammer and drifting tests were required of all steel. For the information from which this description has been prepared we are indebted to Mr. D. L. Fulton, Superintendent, Bureau of Highways and Sewers, Allegheny City, Pa.

A SMOKE INSPECTION SYSTEM has been installed at Pittsburg, with Mr. Jas. J. Brennan as chief inspector. From local press reports it appears that the work at the start will be largely of an advisory character.

THE CONDUIT ELECTRIC RAILWAYS of Washington, D. C., had to shut down on Aug. 12, owing to a severe rain storm, which flooded the conduits and short circuited the conductor rails, causing in some cases a delay of several hours.

◆

THE BOSTON ELECTRIC SUBWAY ran its first regular passenger car over the entire line on Aug. 19. The American Society for the Advancement of Science was holding its annual meeting in Boston, and members of the Section for the Promotion of Engineering Education were the first passengers.

◆

THE NEW YORK STATE COLLEGE OF FORESTRY, at Cornell University, was established by Act of Legislature in April, 1898, and this act authorized the trustees of Cornell to create a department in the University with the above name; establish a demonstrative forest of 30,000 acres in the Adirondacks, which was to be the property of Cornell University for 30 years, and appropriated the sum of $10,000 for the organization and maintenance of this "College Forest." The object of the College of Forestry is to furnish instruction in the principles and practice of forestry and to especially educate managers of forest properties. This college has now been organized, with a full faculty and with Mr. Jacob Gould Schurman as its President. The college year begins on Sept. 22 and closes on June 22, with three terms in each year. A pamphlet has been issued setting forth the requirements for admission, nature of studies and examinations, tuition fees, etc.; and this pamphlet can be obtained by addressing the Director of State College of Forestry, Ithica, N. Y. Tuition is free to students who are residents of New York. The degree issued on graduation is that of Bachelor of the Science of Forestry.

◆

THE EAST BOSTON TUNNEL PROJECT is being discussed before the Rapid Transit Commission in Boston. No less than seven routes are proposed; though the one most favored is that having an opening on the Boston side at State St. or Adams Square and striking Lewis St., and Maverick Square, at the East Boston end. The commission believes that it is authorized to permit the construction of such a tunnel and the consent of the Secretary of War has been asked and a favorable answer is expected. The project is strongly opposed, however, by certain Boston interests. The chief argument used against it is the great first cost and the heavy expense of maintenance. These opponents say that the ferries will still have to be maintained, though their revenue will be reduced by the tunnel traffic; it would not connect with the subway system, and it would be impossible to concentrate existing traffic at the Boston end of the tunnel. The advocates of the tunnel are still to be heard from.

◆

A NICARAGUAN FINE WOODS CONCESSION has just been made to Mr. H. C. Emery, of Chelsea, Mass., for 15 years. This is practically a renewal of an old concession to Mr. Emery under which he shipped about 12,500 logs annually. Mr. Emery is to build 50 miles of a 3½-ft. gage railway between Rio Grande and Pearl Lagoon, and this property is to revert to the government at the end of the concession. He pays $20,000 gold down and $10,000 per year in gold for 15 years. But his concession is said to be exceedingly valuable, as it gives him the monopoly in the shipping of mahogany, rosewood, cedar and other valuable woods; he has also the right to import, free of duty, all supplies for the men engaged in cutting wood and for building and maintaining this railway.

◆

A PLAN TO DEVELOP THE WATER POWER of the Shawinigan Falls on the St. Maurice River, which is about 100 miles from Montreal, Canada, has taken definite form. The head obtainable is 165 ft. with a supply of water estimated to be sufficient to develop 200,000 HP. The Shawinigan Water Power Co. contemplates installing apparatus to utilize about 100,000 HP. Bids are now being asked for the hydraulic construction, as noted in our advertising columns.

◆

THE IRON AND STEEL COMBINATIONS, which has been in process of organization in Chicago for some time, is now authoritatively said to include the following five companies: Minnesota Iron Co., with its Duluth & Iron Range Railway, and Minnesota Steamship Co.; Illinois Steel Co., with its Chicago, Lake Shore & Eastern Railway; Southwestern Connellsville Coke Co.; Elgin, Joliet & Eastern Railway; Lorain Steel Co., of Lorain, O., and the Johnstown Steel Co., of Johnstown, Pa., lately merged with the Lorain Co. The promoters of the combination still hope to later include the Cambria Iron Co., Bethlehem Iron Co., Tennessee Iron & Coal Co., Pennsylvania Steel Co., Colorado Fuel & Iron Co. and the Carnegie Steel Co. The capital of the new combination will probably be $200,000,000; and the five companies named as in the deal have a capitalization of more than $75,000,000; those named as still outside are capitalized at over $90,000,000. The Carnegie Co., however, officially denies having any connection whatever with this trust. The new company would be called the Federal Steel Co., and the syndicate to furnish working capital will be managed by J. P. Morgan & Co., says Judge E. H. Garry for the committee of ten on organization.

◆

CUBA AND PORTO RICAN TRADE is already interesting American manufacturers and shippers. The ending of unstable conditions, bad credits, revolutions and generally unsatisfactory trade relations, existing under Spanish rule, is expected to largely develop the natural wealth and commerce of these islands. In 1893 the total Cuban trade with the United States was about $100,000,000, and $6,500,000 with Porto Rico. In the same year Spain's trade with Cuba was $34,000,000 and $8,700,000 with Porto Rico. Our exports to Cuba, in 1893, was $23,000,000, and business men believe it will be $50,000,000 within five years. More adequate transportation facilities are being already promoted; and Baltimore, among other points, is planning a new line of steamers for the West Indian trade.

◆

THE SOO CANAL TRAFFIC for July last breaks all previous records. The freight tonnage amounted to 3,246,787 tons, as compared with 2,856,767 tons for July, 1897; an increase of 390,020 tons. This record includes both the U. S. and the Canadian canal; the registered tonnage being 2,331,062 for the 2,025 U. S. craft passing, and 314,043 tons for the 559 Canadian craft. The chief items of east-bound traffic were 1,558,564 bushels of grain, 2,055,574 net tons of iron ore, and 2,358,267 bushels of wheat. The total east-bound freight was 2,491,019 net tons, and the west-bound, chiefly coal, amounted to 755,768 net tons The traffic for June of this year was 2,949,465 net tons.

◆

COINAGE DURING THE FISCAL YEAR of 1897 from the United States mint included a total of 102,521,641 coins, representing the following denominations: Gold, 170,473 double eagles, 724,562 eagles, 917,067 half eagles, 19,380 quarter eagles; silver, 4,158,780 dollars, 2,600,780 half dollars, 8,484,780 quarter dollars, and 12,560,780 dimes; base, 19,015,343 nickels and 53,871,696 pennies. The total value was $25,604,792.11, made up of $15,278,865 in gold, $8,836,443 in silver, and $1,489,484.11 in copper and nickel.

◆

TULARE LAKE, in Tulare Co., once the largest body of fresh water in California, is now dried up. About 1872 the lake was about 80 miles long and 35 miles wide at the greatest width, but its depth was never great. Irrigation was introduced into this region in 1872-75, and as the water was drawn off from its tributaries the lake began to shrink in size. In 1895 the lake was only 4 to 5 miles wide; and though it remained stationary in its dimensions for some time, lack of rainfall and increased demands for irrigation upon its former tributaries have finally prevailed, and Lake Tulare has dried up. Farmers are now reclaiming the land and putting it into shape for cultivation, and channels are being made and gates put in to control the waters that a rainy season may send into the old lake basin.

◆

THE BRUGES SHIP CANAL, now under construction in Belgium, was practically started in 1890, with the purpose of again connecting the town with the coast by a canal, with a port at Heyst. Work was actually commenced in 1896 by the Compagnie des Installations Maritimes de Bruges. The canal will be six miles long, 72½ ft. wide at bottom, 229 ft. at the water line and 26¼ ft. deep. The harbor will be formed by a long mole, running out from shore in a curve of 4,000 to 6,000 ft. radius; its end being parallel to the coast line and 2,788 ft. distant at low-water, and including an area of 270 acres. This jetty is solid to low-water mark; and then open for 984 ft. to facilitate the circulation of the tide and prevent deposits of silt and sand. From this opening to the end the jetty is being made of concrete blocks resting on iron caissons, each 82 ft. long by 24 ft. wide and varying in height with depth of water. These caissons are built on shore and floated to their sites, and then sunk by concrete in a dredged bed. The upper part of the concrete caisson blocks, each weighing from 2,500 to 3,000 tons, will be 3 ft. above low water, and on these will be placed 50-ton concrete blocks to a height of 28 ft. above high water. The lock at the end of the ship canal is controlled by a caisson-gate that can be slid into a recess at right angles to the canal in ten minutes, with electricity as a motive power. The work is to be completed in 1902, and the contract price is $7,793,805.

◆

TWELVE RIVER STEAMERS, built by Moran Bros. Co., of Seattle, Wash., were lately successfully sent from that city to the Yukon River, in Alaska, a distance of about 4,000 miles by sea. These boats were each 175 ft. long, 35 ft. wide, with a molded bow and a depth of 6½ ft. They are propelled by a stern paddle-wheel, in two sections, operated by two direct-acting steam engines, with 20-in. cylinders and 7-ft. stroke. They are fitted with a complete electric lighting plant and search-lights. The hulls are built of Puget Sound fir and the general construction is that of the usual vessel of this type. These steamers were to be delivered ready for service at the mouth of the Yukon River, and the Moran Bros. Co. undertook the task of sending the flat-bottomed vessels 4,000 miles by sea; and they have performed this unprecedented feat. The boats were built exceptionably strong with this voyage in view, and the start was made from Roche Harbor about May 25, under Mr. Robert Moran, twice Mayor of Seattle, accompanied by three stout ocean towboats and five coal barges. St. Michaels, near the Yukon, was reached on July 26; but the fleet had passed through two heavy storms; one vessel of the fleet was totally wrecked, but without loss of life, and some of the captains and crews having been frightened off by the earlier experience, the trip was made shorthanded. The route lay along the coast line all the way; but owing to the able management of Capt. Moran, ten of the steamers were delivered in sound condition and the other had sustained slight injury only.

◆

THE DISCHARGE OF THE GREAT LAKES is being determined by the U. S. Deep Waterway Commission, and Mr. Geo. Y. Wisner, M. Am. Soc. C. E., of the Commission, has furnished to the "Monthly Weather Review" the following summary of the results thus far obtained:

> Lake Erie.—The discharge into Niagara River for mean lake level will probably prove to be about 235,000 or 240,000 cu. ft. per second (instead of 250,000).
>
> Lake Superior.—The outflow, namely, the discharge through St. Mary's River, was determined in 1895, by Mr. Haskell, as 72,600 cu. ft. per second for mean lake level, instead of the 86,000 formerly adopted.
>
> Lake Michigan plus Huron.—The discharge of the St. Clair River will probably be diminished proportionately, viz., about 10 or 12%, reducing it from 225,000 to 200,000.
>
> Lake St. Clair.—The discharge of Lake St. Clair, through Detroit River, will fall below 200,000 cu. ft. per second for mean condition.
>
> As regards the run-off for Lake Superior, a fair estimate for the watershed is 40%, as the country surrounding the lake is very rolling and rocky. For lakes Michigan, Huron and Erie, 33% is about right.
>
> Adopting these values we have the following results:
>
> Lake Superior.—Total supply, 4.2 ft.; total discharge, 2.6 ft.; leaving 1.6 ft. for evaporation and errors in the estimates.
>
> Lake Huron plus Lake Michigan.—Total supply, 6.6 ft.; total discharge, 5.0 ft.; leaving 1.6 ft. for evaporation and errors in the estimates.
>
> Lake St. Clair plus Lake Erie.—Total supply, 27.8 ft.; total discharge, 25.5 ft. (adopting 235,000 ft. per second), leaving 2.3 ft. for evaporation and errors in the estimates. Discharge for Lake Huron is probably less than 200,000, which would increase this excess by 20% above the estimate for Lake Huron and decrease that for Lake Erie.
>
> Nothing more definite can be hoped for until the final report of the engineers who are now at work on the physics of the lakes and waterways.

◆

GRANULATED BLAST-FURNACE SLAG BRICK is desribed by F. W. Luerman in "Stahl und Eisen." Brick made from fluid slag is unsuitable as a building material, as it is impermeable to air and makes walls damp and the house unhealthy, says the author. On the other hand, brick made from granulated slag is five times as permeable as ordinary burned brick and much stronger. The fluid slag is granulated by passing it through water, and the silica is separated in a soluble condition so that it hardens quickly in the air and combines easily with caustic lime. These bricks are compressed and not burned; hardening takes place in from 6 to 8 days when about 10% of burned and slack lime is added; but longer for the simple granulated slag. The color of the brick is that of grayish-white sandstone, and as little mortar as possible is used in laying them. The weight varies with the dryness; usually 6,000 bricks make a 20-ton carload. Well hardened slag bricks are claimed to withstand a crushing load of 160 to 180 lbs. per sq. in.; they resist high temperature exceedingly well, and they can be used to advantage in chimneys and stacks. As to absorption, an ordinary burned brick is said to fill its pores with water in 12 hours, while it takes 190 hours to soak thoroughly a slag brick. The best brick is said to be made from puddling and Thomas pig-iron slag; Bessemer and foundry slag rank second. The cost of the slag-brick plant is placed at $5,000; and at several German works the cost of the brick is as low as $2.38 per 1,000. For 1,000 bricks from 6,000 to 7,000 lbs. of slag and 450 to 700 lbs. of burned lime are required.

◆

TO COUNTERACT THE EFFECT OF WATER upon lead pipe, Mr. Liebrich, in the "Zeitschrift fur angewandte Chemie," of July 26, recommends the use of carbonate of soda. He says the essential causes of this attack upon the lead are the joint action of oxygen, or of air and carbonic acid. The presence of bicarbonate of lime in the water limits the dissolving action by apparently interfering with the formation of carbonates of lead and zinc. Mr. Liebrich says that while the carbonate of lime diminishes the dissolvant action upon the metal, it does not arrest it completely. He, therefore, recommends the use of carbonate of soda, in a quantity that is sufficient to fix the carbonic acid, without rendering the water alkaline. He admits that when the water is in active circulation, as in the daytime, the quantity of lead in solution is extremely small; but he contends that in the morning, after the water has stood in the pipes all night, the dissolvant effect is very noticeable.

SUBSCRIPTION RATES: United States, Canada and Mexico, One Year, $5.00; 6 *months*, $2 50; 2 *months*, $1.00. *To all other countries in the Postal Union: Regular Edition, One Year*, $7 60 (31 *shillings*); *Thin Paper Edition, One Year*, $6.31 (26 *shillings*). *SINGLE COPIES of any number in current year*, 15 *cents*.

Mailing addresses may be changed at will by sending both old and new address. The number on the address label of each paper indicates when subscription expires, the last figure indicating the year and the one or two preceding figures the week of that year; for instance, the number 328 *means that subscription is paid to the* 32*d week (that is the issue of Aug.* 11) *of the year* 1898; *the change of these figures is the only receipt sent, unless by special request.*

ADVERTISING RATES: 20 *cents per line. Want notices, special rates, see page* 18. *Rates for standing advertisements sent on request. Changes in standing advertisements must be received by Monday afternoon; new advertisements, Tuesday afternoon; transient advertisements by Wednesday noon.*

The provision of special means for obtaining easy access to the superstructure of large bridges in order to perform the necessary work of inspection, painting and minor repairs is a matter which deserves greater recognition than it has generally received from engineers. European bridge builders have paid some attention to such features in a few instances, and in constructing the great arch bridge at Muengsten, Germany, which is described elsewhere in this issue, an unusually elaborate system of traveling stagings for reaching all parts of the metal work were designed and built by the engineers, but in America we cannot recall a similar structure where such devices have formed a part of the original work. This fact is all the more noticeable, because of the number of really large bridges which we have in this country where suitably designed inspection stagings or platforms could have been constructed at a very small cost, compared with the saving which they would have effected in future inspection and repairs. No engineer need to be told that it does not matter how well a bridge may have been designed and constructed in the beginning, it has to be inspected and minor repairs made frequently thereafter, and it must be periodically painted as long as it is in service. In nine cases out of ten, moreover, it depends upon the ease with which access can be obtained to the metal work which needs these attentions whether care is given to it at once, and when it will result in the greatest benefit, or whether it is deferred until the conditions are such that the work cannot be postponed any longer. It is in some respects one of the most creditable features of the Muensten bridge that every member of the whole superstructure, including the great arch span, can be easily reached by the engineers or inspectors who may for any reason desire to examine it.

◆

An interesting interview with Admiral Sampson upon the war appears in the Boston "Journal" for Aug. 21. As Admiral Sampson was formerly Chief of the Bureau of Ordnance in the U. S. Navy Department, and is a widely acknowledged authority upon all that pertains to gunnery and explosives, his opinions as here expressed are worthy of the fullest consideration. In the first place he says that this war has taught many things to naval experts throughout the world; and one of the chief of these is the absolute necessity of making warships fireproof. He would not stop at the fireproofing of wood, but recommends that ships should be built practically without wood at all. As to torpedo boats, he warns the people who believe that boats of this type have been shown to be practically useless in naval warfare, that torpedo boats have never had a really fair test in this war. Those in use have been faulty in construction and equipment; and, as a rule, necessary qualities have been sacrificed to speed until they are mere egg-shells. Admiral Sampson contends that torpedo boats have their legitimate uses, but they should be made stronger, and there is no good reason why they should exceed a speed of 25 knots. In regard to the contention that 8-in. and rapid fire guns did most of the execution at Santiago and Manila, it is pointed out that the Spanish fleet at Manila was lightly armored; and at Santiago, the lightly armored parts were exposed to destruction, and it was these portions that were so badly wrecked. When it comes to piercing armor the large-caliber guns must be used, for the armor-piercing qualities of naval guns are almost exactly proportioned to their caliber; for example, an 8-in. gun will penetrate 8-in. armor, but a 12-in. projectile is required to penetrate 12-in. armor. Admiral Sampson says that smokeless powder should be at once supplied to our warships for several reasons. The most important of these is the resulting increase in velocity, from about 2,100 ft. per second for ordinary powder, to about 2,500 ft. for the smokeless powder. The smoke from the combustion of ordinary powder is also a great disadvantage, as it interferes with the sighting of neighboring guns, and consequently decreases the accuracy and rapidity of fire. One remarkable point made by Admiral Sampson is that out of 12,000 men engaged on the fleets there have been only 20 casualities throughout the war; a record unprecedented in any previous naval war. He ascribed practically all of the success of our ships to the fact that the United States navy is always upon a war footing; and ships are handled with as much exactness and discipline, and target practice is carried out with as much care and precision as if an enemy were constantly in sight. The same remark applies to the distribution of supplies and to the care of the well and the sick on board of our vessels. This generally excellent physical condition of our man-of-wars men is most remarkable, when it is remembered that some of the crews were not off their ships for more than six months.

◆

Our attention has been called to an error regarding the names of the members of the Deep Waterways Commission, mentioned under "Notes in Detroit," in our issue of Aug. 18, 1898. Mr. Geo. W. Rafter, M. Am. Soc. C. E., is not a member of the Commission, but is its engineer in matters relating to the water supply of the canal, control of floods of tributary streams and allied matters. The third member of the Commission is Col. C. W. Raymond, M. Am. Soc. C. E., of the U. S. Engineer Corps.

◆

THE REDUCTION IN RAILWAY TRANSPORTATION RATES IN THE UNITED STATES.

The decrease in railway passenger and freight rates in the United States since 1867 is made the subject of a special report recently published by the Division of Statistics of the Department of Agriculture. With a wealth of figures which we have never seen equalled regarding the subject the report traces the reduction in rates of transportation for the railway system of the country as a whole, and also for a large number of individual railways in widely separated geographical locations. In no case subsequent to 1868 do the former figures represent less than one-third of the total railway mileage of the country, so that they afford a fairly true index of general conditions. Their value for deduction is further increased by the fact that they have all been reduced to a gold basis, and are, therefore, susceptible of absolute comparison, which is not the case with many similar statistics where this reduction to a common basis has not been made.

To enable our readers to make these comparisons for themselves the accompanying table has been compiled from the detailed figures given in the report. This table, as will be seen, shows both the average freight rate per ton mile and the average passenger rate per passenger mile for each year from 1867 to 1896, inclusive. The decrease in freight rates per ton mile since 1867 has been fully 60 per cent.; that for passenger rates has been smaller, but except for about ten years previous to 1878 these charges have also shown a continual decline.

Table Showing Railway Rates in Cents per Ton-Mile, and Cents per Passenger-Mile, from 1867 to 1896, Inclusive.

Year.	Average cents per ton mile.	Revenue cents per pass. mile.	Year.	Average cents per ton mile.	Revenue cents per pass. mile.
1867	1.925	1.994	1882	1.102	2.391
1868	1.810	2.164	1883	1.204	2.402
1869	1.709	2.144	1884	1.136	2,323
1870	1.889	2.392	1885	1.011	2.216
1871	1.789	2.632	1886	0.999	2.142
1872	1.846	2.521	1887	0.984	2.245
1873	1.613	2.486	1888	0.941	2.108
1874	1.520	2.544	1889	0.922	2.165
1875	1.421	2.378	1890	0.941	2.167
1876	1.217	2.183	1891	0.895	2.142
1877	1.286	2.458	1892	0.898	2.126
1878	1.296	2.573	1893	0.878	2.108
1879	1.513	2.484	1894	0.860	1.986
1880	1.232	2.442	1895	0.839	2.040
1881	1.188	2.446	1896	0.806	2.019

While the means by which this steady reduction in the charges for freight service has been brought about are in a general way at least familiar to most engineers, they will bear being briefly restated. It is not always fully realized that, noteworthy as the reduction in the charges for carrying freight has been, it has been made possible only by a far more remarkable decrease brought about in the cost of carrying it. This has been due to a variety of economies resulting directly and indirectly from the general mechanical and commercial development of the country.

The mere growth of the country itself, offering a larger and more varied traffic and enabling the railways to utilize their facilities more fully, has obviously been a very important factor in bringing about greater economy in cost of transportation. A part of the gain has also been due to consolidation, by which connecting railways have been enabled to administer their affairs more cheaply. But the most notable part has been due to improved methods of handling the traffic itself, which have been made possible by the general introduction of more powerful locomotives and larger capacity cars, and by improving the roadbed, track and structures to withstand these increased speeds and loads.

With the increased capacity for doing business, railway managers arranged their rates to secure this business, without which it is needless to say the improvements in rolling stock and track would have amounted to very little. Gradually the fact came to be realized by the railways that for obtaining freight to fill their cars any rate was a paying rate when it would cover the difference between hauling them empty and hauling them full, provided, of course, that such rates developed additional business which could be obtained in no other way. The universal recognition and observance of this principle has been the largest single factor in making possible the extreme low freight rates of America as compared with other countries.

Interesting evidence of how this reduction of empty car mileage has acted is found by comparing some of the figures given in the report from which the above table was compiled. These figures show that the increase in the average number of tons of freight hauled one mile per mile run by freight trains has been from 81 tons in 1867 to 111 tons in 1877, 155 tons in 1887, and 199 tons in 1896. In other words, the increase in the efficiency of freight train service has made it possible to perform twice as much transportation per mile of line in 1896 as in 1867, without increasing train mileage.

These factors, which have had so much to do in reducing freight rates, have not been equally influential in reducing passenger rates. The reasons for this are obvious upon a little consideration. It must be remembered, however, that though it may appear from the table that the decrease in the charges for the transportation of

passengers has not been as great as that in the charges for freight service, the thing which the traveler purchases with the money paid as fare has varied in his favor in every important element except that of distance. The dollar with which a man purchases transportation on a modern fast passenger train, provided with air brakes and automatic couplers, running over stone-ballasted track laid with 80 and 100-lb. rails, and on a line equipped with block signals, purchases vastly more than a dollar paid 30 years ago, or, for that matter, even a decade ago. Studied in this light the apparently small decrease in passenger rates shown by the table assumes a different aspect.

So much for the methods by which the enormous reduction in railway rates in a single generation has been brought about. There is another phase of the subject, however, which is not brought out in the report, and which deserves to be considered. Statistics show that while the decrease in the cost of hauling freight and passengers has been coincident with the reduction in the rates charged, yet this decrease has been relatively smaller. On the Lake Shore & Michigan Southern Ry., for example, where these figures have been compiled on a uniform basis for the past 28 years, we find the following relative figures of income, cost and profit per ton mile, and per passenger mile at five-year periods:

	Freight service			Passenger service		
	Income, cts.	Cost, cts.	Profit, cts.	Income, cts.	Cost, cts.	Profit, cts.
1870	1.504	.932	.572	2.612	1.708	.904
1875	1.010	.737	.273	2.378	1.824	.554
1880	.750	.435	.315	2.135	1.086	1.049
1885	.553	.399	.154	2.058	1.250	.808
1890	.626	.458	.168	2.246	1.492	.754
1895	.561	.410	.151	2.139	1.368	.771
1897	.545	.356	.189	2.018	1.407	.611

Similar results are obtained when we analyze the figures published during the last few years in the statistical reports of the Interstate Commerce Commission covering the railways of the United States as a whole, showing that the particular figures given above are fairly typical of general conditions.

It is clear that the approximation of cost and income shown by such statements cannot contiuue indefinitely; the time must come when no margin will exist for a further reduction of freight rates particularly. Already, in fact, there are prominent railway managers who assert that this point has been reached, and that if railway rates are reduced further, the saving must come by reducing wages, or by practicing false economies in maintenance and renewals. Evidently the questions whether this statement is justified, and whether we can expect no further reduction in railway rates are worth some trouble to answer.

First of all, it is worth while to inquire whether the influences which have done so much to reduce the cost of railway transportation in the past have lost all their power for securing further economies. It will be admitted, we believe, that consolidation yet has something in store for us by further reducing expenses due to competition and the duplication of managements. But without going so far as this, it may be seriously questioned whether the efficiency of train service has been brought to nearly as high a standard as it is capable of reaching. Notwithstanding the great growth in the proportion of paying load hauled by freight trains, the average train load to-day is far below what is possible with modern equipment. Few engineers also will be ready to admit, we think, that no further economies are to be expected from the mechanical and engineering department of our railways.

No such revolution probably will ever again be wrought as that which followed the introduction of the steel rail, but a multitude of minor economies, the possibilities of which are being found out and improved each year, are gradually reducing the important items of expenses coming under the heads of maintenance of equipment and of maintenance of way and structures. In both these departments, notwithstanding all the improvements which have been made, the tools for conducting transportation are in many cases those designed for other conditions than they are now called upon to meet, and they are not, therefore, economical. No better evidence of this is needed than the constant progress being made by railways in replacing their old structures with new ones more durable and better fitted to perform economically the duties which devolve upon them.

The opportunity open to the traffic department to increase the efficiency of train service has already been mentioned. As the natural resources of the country are developed and its industrial life enlarges, offering a larger traffic, it will become easier to realize this opportunity, and it cannot be doubted, we think, that the future will show a material reduction in the figures of empty car mileage. But it must appear to anyone who studies the subject, we imagine, that more direct economies than this are still possible in conducting traffic. Take for illustration the single item of expense resulting from the employment of the present army of freight solicitors and the multiplication of outside agencies bidding for competitive traffic. Men well informed in railway traffic affairs freely acknowledge that, taken as a whole, these outside solicitors and agencies cost the railways more than they come to, and the crop of wastes and worse evils which has grown up about the practice is familiar to every student of railway traffic affairs.

The opportunities for further economies in the cost of hauling freight which have been mentioned, and others which will doubtless occur to the reader, indicate then that there is still room to reduce freight rates, low as they already are. Not the least important result of this conclusion is the force with which it exhibits the enormous and almost controlling factor which the steam railway has become in the transportation system of the United States. This is a matter which the advocates of ship canals have been slow to understand. As we have frequently asserted, it has yet to be shown that, when all the factors are fully considered, the margin between the cost of shipping freight by canal and shipping it by rail, even at the present rates, will pay for the cost of constructing such enormous waterways. But instead of a system which has reached its limits of economy in transportation in its present schedule of rates, these canals will have to compete with one which is evidently capable of still further reducing the costs of operation. This is a matter, however, which we have already considered at length, and with this brief reference it will not be alluded to further here.

A suggestive comparison which may be made in conclusion is the relation between the average yearly farm prices and railway rates during the period covered by the large table above. It appears from quite complete figures covering this point, which are given in the report, that for any series of years except the earliest, which may be selected, the decline in railway rates has been greater than the decline in the price of any of the leading staple crops. Wheat has declined in price 23 per cent. less than railway rates, and hay fully 12 per cent. less. The cost of shipping anthracite coal from the mines to tide water is to-day less than half what it was in 1869, but its price has decreased only about 10 per cent. in the same period. Similar results are obtained when the reduction in price of other commodities is compared with the decline in the rates charged by the railways for transporting them.

LETTERS TO THE EDITOR.

Notes of an Engineer in Colorado.

Colorado Springs.—This city has long stood in a class almost by itself, as being the largest in the West dedicated almost exclusively to the health and pleasure seeker. It is also the headquarters for most of the large mining enterprises of the Cripple Creek mining camp near here. The city is the chief point for side-trips to the several summer and pleasure resorts in this locality, of which Manitou is the most important, and also for visits to many of the most noted scenic attractions in the country. The streets and avenues are of generous width, 100 ft. and 140 ft. respectively, and the city extends over much territory. Notwithstanding this, however, the street car system seems to have been planned more with an eye to reaching the outside resorts than to the convenience of the citizens, and though 40 miles of track run through and out of the city the facilities, except for two or three of the principal streets, are quite poor. The line to and through Manitou take almost seven miles of track, the one to Cheyenne Canon, five miles, and the one to Roswell (a suburban railway town north of the city) about the same. No center poles for the trolley wires are allowed, which makes an excessive length of cross-wire between the pole lines near each curb.

Colorado Springs was one of the first cities to use street car sprinklers. The American Street Sprinkling Car Co., of Worcester, Mass., is operating one of its sprinklers here, the local street car company furnishing the power and the motorman. The car has an arm about 20 ft. in length, extending out horizontally, to sprinkle from. The car holds about 2,500 gallons, which makes a very heavy load on the rails. During the summer it is started early in the forenoon and is kept going all the day.

The city has about 30 miles of sewers, ranging in size from 6 ins. to 21 ins. The separate system is used. It was begun in 1888, and 1½ to 2 miles are being added yearly. The city, as stated in Engineering News of Feb. 23, 1893, adopted irrigation as a means of sewage purification, and the method worked well until the summer of 1894 when the unprecedented flood, due to the cloud-bursts in this vicinity, overran the sewer farm on the banks of the "Fountain Qui Bouille" or Fountain Creek, practically ruining it. Since then the sewage has been turned directly into the creek. This has renewed the old conflict with the landowners below the outlet, and the city is now considering the question of using the sewage again for irrigation, but on a larger scale and further removed from the city than before.

Colorado Springs has a water supply system with many interesting features, which was described at length and illustrated in Engineering News of Aug. 27, 1896. The most prominent part that lacked completion at that time was the Strickler Tunnel, intended to divert the water from the west slope to the east slope of Pike's Peak. I learned that this tunnel was not near completed, though 2½ years had elapsed since the letting of the contract. On the east end the rock was extremely hard and wholly without cleavage, requiring the rock to be literally honeycombed with drill holes, which even then blew out a very small quantity of material at a blast. The rock at the west end, while not nearly so adamantine, was seamy, which in addition to interfering with drilling developed large quantities of water. This had to be pumped out, as the grade here is descending. A large crevice filled with water, sand and gravel was encountered last November, and this led to making a detour from the center line to avoid it. Early this July the same crevice was struck some 12 or 15 ft. to one side of the center line, letting loose such a flood of water that for a while it was reported that the undertaking would have to be abandoned. The contractor is now making a wider detour than formerly. While it is tedious work to go through these crevices it is not at all impossible.

The tunnel is to be 6,242 ft. long, and it is hoped to complete it this year. While it is realized that the contract price—$100,000—will not nearly compensate the contractor, he is intent on saving his $50,000 bond. The electrical disturbances of the power machinery, difficulty of getting in supplies, etc., have done much to delay the work.

The Beaver Creek 16-inch main is also being paralleled this year. This supply main carries water from the Middle Beaver Creek to the top of Seven Lakes Divide. During the past two years the distribution system of the city has been steadily extended. About all of the public engineering works of Colorado Springs have been designed and carried out by Mr. H. I. Reid, who was city engineer for 14 years until April 18 of the present year. Mr. Reid is now conducting a private office as civil and consulting engineer, in the Gazette Building.

Colorado Springs is connected with Colorado City and Manitou on the west by two steam and one electric railways, and also by the main wagon road and a scenic driveway called the Boulevard. Colorado City—half-way to Manitou—was the first capital of the territory, but sadly fell behind all its competitors. On the building of the Colorado Midland Ry. to Leadville in 1887, however, the location of the shops here gave this town new life. And within the past two years a large chlorination plant for the reduction of the gold ores from Cripple Creek has been built and put in operation. These are just southwest of the city, and four miles from Colorado Springs. The present haul of the ores from Cripple Creek is 50 miles, but mostly down hill. Much is expected of the electric railroad now building to give a more direct connection between these two towns and the Cripple Creek district. The projected line runs up Bear Creek Canon from here directly toward the mining camp in a southwesterly direction. The haul to the reduction works will then be 25 to 30 miles, and the intention is to have several other plants built by the time the road is completed.

Pueblo.—Pueblo has been called the "Pittsburg of the West." The city now has a population of between 35,000 and 40,000. The smelters, steel works and railways are the three classes of industries that furnish the bulk of the employment to the workingmen, and there are about 75 smaller manufacturing institutions. About 5½ million dollars per year are disbursed in wages, on account of the industrial enterprises, or about $15,000 for every day in the year.

The three smelters, the Pueblo, Philadelphia and Colorado, had an output in 1897 of over $20,500,000 in value of gold, silver, copper and lead. This was an increase of over $5,000,000 on the product of 1896, which was the largest heretofore. Notwithstanding the great decrease in the prices of the three latter metals since 1892, before the great slump in silver, the output of the smelters has nearly doubled since that year. The amount of gold turned out increased from 50,000 ozs. to 313,000 ozs., nearly entirely due to the discoveries at Cripple Creek. The Pueblo Smelting & Refining Co.'s smelter has the largest value of annual product of any in Colorado, and Pueblo for some time has held the position of the first smelting city in the world.

The Bessemer steel works of the Colorado Fuel & Iron Co. is the largest manufacturing plant in the state. When built in 1881 it was up-to-date in every respect, but most of the machinery became antiquated so that lately the plant has not been able to compete with those in the East having the modern improvements. In rolling rails, for instance, the handling has been almost entirely by hand. Early during the present year the plant was completely overhauled, and all of the old machinery except that in the nail mill and bolt factory was replaced by the latest improved. The rail mill, the plate mill and the structural steel mill have now the automatic mechanical devices for carrying the steel through from one set of rolls to the next without handling by hand. The rail mill has a maximum capacity of 1,200 tons daily. The rollers are of the interchangeable pattern and can be so adjusted as to handle structural iron when the demand for rails is not large enough.

It is recognized that the manufacture of structural and merchant iron and steel has become more and more the leading industry for rolling mills. About $450,000 were spent in these improvements. The whole plant will employ 2,500 men when all departments are running. In the mill 50,000-lb. and 20,000-lb. Shaw electric cranes are now used, where formerly only jib cranes were employed. For work in the yards there is a heavy track crane built by the Industrial Works of Bay City, Mich.

During 1897 the production of the works, in round numbers in pounds, was as follows: Merchant iron, 38,000,000; spikes, 4,300,000; bolts and nuts, 3,400,000; cast-iron pipe, 11,000,000; castings, 1,600,000. These were large increases over 1896, particularly in pipe. The pipe foundry does not run constantly like the others. It was idle for two months early in 1897, and for several months during the present year. The steel works supply material directly that is used over much of the West, and their product worked into forms for mining mill plants finds its way all over the globe.

The Colorado Fuel & Iron Co. is the largest of the kind in the West. It owns and operates many mines of coal and iron and numerous coke ovens in southern Colorado and New Mexico. A force of 7,000 men is employed. During 1897 the product of the mines and coke ovens was $4,000,000, and of the steel works $2,000,000 more; a total of $6,000,000. Of this about 84% was distributed as operating expenses. As stated before, the company produces its own iron and steel for the Bessemer works. The general headquarters of the company are at Denver.

Pueblo has some municipal works of considerable interest. The Arkansas River runs through the center of the city from east to west, thus dividing it into North and South Pueblo. This river is subject at times to tremendous floods, some of which have overflowed the business and manufacturing districts along the bottom lands and have done much damage. Large sums of money have been spent by the city in constructing earth and slag levees and masonry walls for confining the waters within proper channels. About $50,000 was spent on this work in 1897, and $50,000 more is being spent the present year. The official width of the river through the city is 152 ft. The large amount of slag available at the smelters here allows of its being used very cheaply for rip-rapping the earth embankments. This substance, as it comes from the slag-pots in a hemispherical form, allows of being broken up into shapes that make an ideal material for steep rip-rapping, the pieces being laid in snugly and with the smooth surface next to the water. Where stone masonry is used the walls are vertical and on the line of the established river channel. At three of the principal streets the river is spanned by "triple triangular" truss bridges, a very unusual type in the West. Two of these are made wide enough to include street car tracks. All are single span. There are three large viaducts crossing the numerous railroad tracks along the low lands, one of 1,050 ft. length and two of nearly 400 ft. length each.

Pueblo's sewer system, as originally planned, was the Waring, but it has been added to by different city engineers and changed a good deal. The city has a very fair electric street car system that reaches the more important parts of the city and suburbs. The return current is conducted through a continuous wire laid between the rails. No paving has been done by the city as yet. The railways have a fine union depot in South Pueblo, completed in 1890, and some of them also have separate depots on the North side.

Florence.—Florence is the center of the most important oil producing region in the West. All the illuminating oil for Colorado, Wyoming, Montana, Utah and New Mexico (except for the east part of Montana and southeast part of New Mexico) is produced here. The Continental Oil Co., of Denver, a branch of the Standard Oil Co., supplies this oil, buying it from the refineries at Florence. There are over a half-dozen companies around Florence that produce oil, but it all goes to two large refining companies here. The production of the wells for 1897 was about 2,000 bbls. per day, while the capacity is 3,500 to 4,000 bbls. In refining, about 33% to 35% of the crude oil is obtained as refined petroleum. There is a great demand for the fuel oil which is a residue from the distillation. In the past most of this has been shipped, but during the last year there has been a great demand for it by the several gold reduction works here, for roasting the Cripple Creek ores in the treatment by cyanide, chlorination and smelting processes; consequently much less fuel oil is now available for shipment. Lubricating oils, axle grease, etc., are other oil products.

The Florence oil fields were first opened up in 1885, and since then drilling has gone steadily on. The wells usually run from 1,500 to 3,000 ft. deep, and the oil has to be pumped from 1,500 to 2,300 ft. An 8-in. casing is first put down (generally to bed-rock), then a 5⅝-in. one, then a 4¼-in. one, and finally a 2-in. one, all inside of one another. The oil rises in and is pumped from the 2-in. pipe, and the gas rises between it and the 4¼-in. pipe. Gas is obtained at many of the wells, and the pump rod for oil is then at one end of the walking beam of the engine, while the gas is led to a pump cylinder worked by a rod at the other end. The engines for pumps are usually of 15 HP., the pumps of 14-in. stroke and forcing oil at each stroke. The gas is forced through mains and used by numerous families for domestic purposes. No wells producing less than 10 bbls. per day are pumped here, and they run from that up to 200 bbls. Each well has a derrick of standard style, 74 ft. high. The residuum or fuel oil is used as fuel at both the wells and refineries.

Extensive coal beds are also found in the vicinity of Florence, and the coal camps to the southwest of town ship all the way from 700 cars in the summer to 1,800 cars per month in the winter time.

Cripple Creek Mining District.—I took a run from Florence up to this famous district, spending two days at it. The center of the district is but a few miles southwest of Pike's Peak and just behind the front range of the Rocky Mountains.

The history of Cripple Creek reads like a romance. In 1859, during the Pike's Peak excitement, prospectors passed through this region, but being totally unfamiliar with the occurrence of gold in compounds they little realized the stores of latent wealth they were leaving behind. In 1891 attention was drawn to the gold that was occasionally found in its free state in the gulches. At that time this region was but a "cow pasture," taken up by rangemen who roamed the hills with their herds of cattle. The first substantial results were obtained in Poverty Gulch, running through the present city of Cripple Creek. Outsiders were slow to believe that any great wealth could come out of this district. The people of Colorado Springs were the first to put faith in the value of the discoveries, and as a consequence more persons of this town have been rendered wealthy by this district than in all the rest of the country besides.

The output increased from 10,000 ozs. in 1891 to 100,000 ozs. in 1893, but the public at large was still skeptical as to the permanency of the district. In the latter year the closing down of the silver mines resulted in a large influx of skilled miners and prospectors into this region. By the end of the year public opinion was changing, and during the next year much capital from Denver and the East was invested. The first railway reached the district in 1894. During this year, however, occurred the great strike, which curtailed production and development, though the former reached 3¼ million dollars.

Geologically considered, the district consists of a granite floor upraised in the central portion above the general average level of the surrounding country, in the form of a very irregular basin. In this basin at the close of tertiary time a violent volcanic outburst took place, which formed the present surface of the ground and resulted in the mineralization of the district. The fissures in the ground were filled with silicious waters carrying gold and other metals. So at the present time the gold is usually found in quartz veins surrounded by a porphyritic breccia. Owing to the action of the elements the ores have been oxidized to depths varying from 50 to 400 ft. below the surface. Below this zone the "live" ores are reached mostly in the forms of sylvanite and calaverite, chiefly the latter. The average composition of the ores shows the following proportions: Tellurium, 57.45%; gold, 40.6%; silver, 1.95%. The compound often has a steel-gray color, in appearance like a fracture. At the Independence Mine, where the vein is of very high value, it may be seen in bands of ¼-in. thickness spaced about 3 ins. apart. The number of mines shipping or in a position to ship at the close of 1897 has gradually increased to 250.

All the mines are worked or reached by means of shafts, and though several long tunnels are projected and under construction for the purpose of tapping the mines at greater depth (thereby serving for hauling out ore and for drainage) none has yet reached the depth to become a factor of much consequence. The production of the camp has increased year by year, until in 1897 it was over $12,000,000 or $1,000,000 per month. This placed Colorado in the front rank as a gold-producing state, her output for that year being between $21,000,000 and $22,000,000. California, which had before held the lead, contributed only $17,000,000 in 1897. Of the $61,500,000 produced in the United States, Cripple Creek is thus credited with one-fifth. At the present time the output is about $1,250,000 per month.

Of the leading mining companies here, the Portland stands at the head. It was incorporated March, 1894, with a nominal capital of $3,000,000 in $1 shares. The production increased from about $600,000 to over $2,100,000 in 1897. The Portland group comprises about 135 acres on Battle Mountain. The main working shaft is now down about 800 ft., has a hoisting engine of 600 HP., with drums of 14 ft. diam., and carrying a 6-in. flat rope cable, and has double-decked cages. The engine can hoist at the rate of 1,000 ft. per minute. The company pays regular dividends of 1% per month on the par value of the stock.

The Independence Mine, situated on the same mountain, is owned by W. S. Stratton, the eccentric millionaire, and its returns are not made public. Its output has averaged over $1,000,000 for the past three years. The Victor Mine is the oldest of the large producers, and its product has averaged nearly $500,000 the past three years. The average value per ton of ore from 47 of the principal properties has varied from $30 up to $350, this latter being the average value of ore from the Orizaba Mine, from which 353 tons have been shipped. The average value of milling ore at present is $25 to $30 per ton, of smelting ore (which is shipped much farther than the last) is $75 to $90. About one-third of all the ore is sent to the smelters.

During the early days of the camp a great mistake was made in assuming the ores to be free milling, and a number of stamp mills were erected which were found to save only a portion of the value in the ores. Some of these, however, are still run to treat ores of too low a grade to justify treating by any other process. But the chlorination and cyanide processes are now used nearly entirely for all ores not rich enough to send to smelters.

The first named process is more regular and adapted to a larger variety of ores than the second, but is more expensive. In cyanidization, as well as in chlorination, roasting is used on the Cripple Creek ores before leaching, except for the oxidized ores near the surface. For the sulphide and telluride ores roasting is necessary. Ores of whatever kind have to be roasted in the chlorination process. The chloride of lime and the sulphuric acid required in the chlorination process are much more expensive than cyanide of potassium, and the process also requires lead-lined vessels. The chemistry of the cyanide process is more complicated, however. For treating the Cripple Creek ores there are at present 9 reduction plants in operation, five using the cyanide and four the chlorination process. Five of these plants are at Florence and vicinity, one at Colorado City, one at Gillette, and the other two in the heart of the camp. The Metallic Extraction Co.'s cyanide plant, near Florence, has a capacity of 400 tons per day.

At Colorado City is the great chlorination plant of the Colorado-Philadelphia Reduction Co. Over a dozen buildings contain the machinery for the reduction of the ores, and the capacity is 250 tons per day. The process here is as follows: After being finely pulverized at the roll house, the ores are conveyed to the roasting department, 90 × 160 ft., where they are passed through two immense Ropp roasting furnaces, each with a capacity of 150 tons per day. From here they pass to the cooling room and thence to the chlorination department or barrel house, 68 × 150 ft. Here are 10 revolving barrels, each 6 ft. in diam. by 14 ft. long, of iron lined with lead, and with a capacity of 10 tons to each charge or 30 tons per day. In these the ores are chlorinated through the affinity that gold has for chlorine gas, the gold being extracted and converted into a chloride of gold solution. In this form it passes through a series of sand filters, from which the liquor passes into the eight immense tanks of the settling and precipitating departments, where any remaining slimes are settled. The clear liquor is then decanted into six precipitating vats below, where the gold is precipitated by the use of sulphureted hydrogen of gas, producing gold sulphide. This is pressed and dried and is then ready for melting in the crucible furnaces. From these the gold bullion—950 fine—is shipped for refining at the government assay offices.

The growth in population of the Cripple Creek district has kept pace with the mining development, and as a result a community numbering over 40,000 souls is now included within its bounds, where a few years ago less than 100 persons (all males) were to be found. The city of Cripple Creek—the metropolis of the district—contains between 15,000 and 20,000 people. In April, 1896, nearly the whole of the city was destroyed by two fires that rendered 15,000 people homeless. It has since been rebuilt, and the shacks so characteristic of a new mining camp replaced by substantial buildings.

The city has an excellent water-works supply. The water is obtained from Pike's Peak and conveyed through an 8-in. pipe line for 5 miles to a reservoir above town, which gives about 80 lbs. pressure. The distribution system consists of 8-in., 6-in. and 4-in. pipe. The works were built by and owned by the Michigan Pipe Co., of Bay City, Mich., who used their bored log pipe (wrapped spirally with flat bands) of the Wyckoff pattern. Iron is used only at T's, etc. The pipe was made at their factory. After being bored, it was dipped in coal tar, then banded, then dipped again and rolled in sawdust, which last protects the tar and allows it to be handled. This pipe is well suited for this country on account of rock being so near the surface, as it can be laid in a much shallower trench than iron pipe as regards freezing. It came in lengths of about 10 ft. Water rates are reasonable, the charges for a six-room house being only $22 per year.

The other principal town of the district is Victor, which, though only four years old, has a population of 8,000 to 10,000. This is more nearly a typical mining town than Cripple Creek, most of the large mines (including the Portland and Independence) being located quite near by.

Power for operating the mines has become quite an item of expense in the Cripple Creek district. All coal has to be hauled in, and there has been presented the interesting problem of whether it would be cheaper to (1) bring fuel in from the coal camps, 25 or 30 miles off, and 4,000 to 5,000 ft. lower, or (2) to generate electricity right where the coal is produced and transmit it for power purposes to the mining camp. One large mining corporation has decided on the former, and is building a plant of its own at Goldfield—about a mile from Victor. It will have three 750-HP. steam engines. The Colorado Electric Power Co. believes there is money in the latter method, and it has lately completed a plant for a 26-mile transmission from Canon City to the center of the camp.

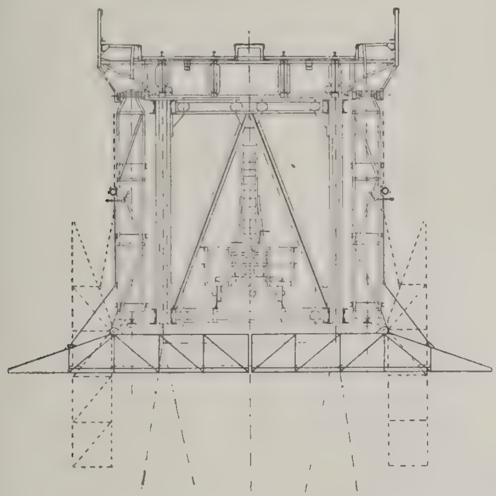

Fig. 5.—Traveling Inspection Platforms for Truss Spans; Muengsten Bridge.

Canon City is eight miles west of Florence, at the mouth of the Canon of the Arkansas River, and adjoining the famous Canon coal fields. Here on the river bank is the power house plant. The main building is 100 × 106 ft., and the converter building 27 × 72 ft. The principal machinery consists of three Hamilton-Corliss engines of cross-compound type; three three-phase 470-K-W. generators and four converters. All electrical machinery is Westinghouse make. Power is furnished by four 300-HP. Heine boilers. Room is left for a duplicate plant to be erected at the west end of the present buildings, when needed. Two shifts of ten men each are required to operate the plant. The direct distance by the transmission line to distributing station No. 1 (on the south slope of Bull Hill and between Victor and Cripple Creek) is 26 miles. The voltage is reduced here and lines are run to the different consumers.

An electric railroad called the Canyon City & Cripple Creek Electric Ry. has long been projected to connect the two places by a line much shorter than possible with a steam road, but it does not seem to have made much progress yet.

Resuming the journey to Leadville, Canon City (already noted) is first passed. The state penitentiary is located here. Several years ago an attempt was made by the state to utilize the labor of the convicts here in the construction of a large irrigation canal, called State Canal No. 1. A line was located, tapping Arkansas River within the mouth of the canon and running east as far as Pueblo. A large amount of work was done and a great expense incurred in outfitting the convicts, transporting them to and from the work and in guarding them. But finally a halt was called, as it was claimed that there would be no unappropriated water left for the canal even if built. A committee of the Tenth General Assembly was appointed to investigate and report as to the advisability of continuing work, which made a very able report advising abandonment of the project. This was done, and the only evidence now left of the work are the numerous tunnels and cuts in the rocky side of the canon near the town. W. P. H.

Salt Lake City, Utah, Aug. 1, 1898.

GRAVEL ROADS aggregating 40 miles in length are being built in Lake county, Ind. The excavation and grading is done by scrapers and then a bed of furnace slag is laid and covered with a top dressing of gravel, making a total thickness of 11 ins. at the middle. Formerly a 12-in. bed of gravel was used, but the slag costs only about half as much and makes a better foundation. The railways are assessed for taxes for this work, and in some townships pay 75% of the cost of the work, which may account in part for the people's desire for good roads. Mr. John Halloran, of Hobart, Ind., is the contractor for the work.

DOUBLE TRACK STEEL ARCH RAILWAY BRIDGE, MUENGSTEN, GERMANY.

(With double-page plate.)

The Muengsten Bridge, some of the principal features of which we illustrate on our double-page plate this week, was built to avoid a long detour in the line of railway connecting the towns of Solingen and Remscheid, lying on opposite sides of the deep gorge of the River Wupper, in Prussia. At the point where the bridge crosses it, this gorge is about 350 ft. deep, with sides inclined from 18° to 47° to the horizontal, and the parabolic arch springs from points on the opposite banks about 590 ft. apart, The stream itself is of small size, and offered little obstruction to erection.

Plans were submitted by four different engineering firms for the bridge, but the one finally adopted was that of the Nuremberg Machine Works, Ltd., Mr. A. Rieppel, Engineering Director. From a description by Mr. Rieppel in "Zeitschrift des Vereines Deutscher Ingenieure," Mr. O. J. Marstrand has abstracted the following information relating to the design and erection of the bridge. The accompanying illustrations have also been reproduced from the columns of the same publication.

The bridge, Fig. 1, is designed for two tracks and consists of a parabolic arch spanning the center opening and flanked on each side by steel viaduct approaches. The span of the arch c. to c. of abutments is 170 m. (357.8 ft.). On the Remscheid side the viaduct consists of three trestle towers, carrying one 30-m. (98.4 ft.) and two 45-m. (147.6 ft.) truss spans, and on the Solingen side of the same number of towers carrying two 30-m. and one 45-m. spans. The dimension of the tops of the towers in the line of the axis of the bridge is 15 m. (49.2 ft.). The total length of the bridge is 465 m. (1,525 ft.). Over the center span the continuation of the viaduct truss is carried by verticals to the arch proper below, spaced 30 m. and 15 m. apart, and by the crown of the arch itself.

The parabolic arch ribs have a web system of vertical and diagonal members forming a rib 4 m. (13.1 ft.) deep c. to c. of chords at the crown and 12.206 m. (40.05 ft.) deep at the abutments. The distance between the verticals or the panel length is 7.5 m. (24.6 ft.) The arch ribs are inclined inward 1 to 7 to the vertical, so that they are 5.0 m. (16.4 ft.) apart c. to c. at the crown; 25.685 m. (84.27 ft.) apart at the feet of the inside ribs, and 23.681 m. (77.69 ft.) apart at the feet of the outside ribs. The lateral wind-bracing is attached to the lower ribs, while the wind-strains in the top ribs are resisted by transverse bracing between the verticals; in the end panels this bracing is carried to the base of both the upper and lower ribs.

The sides of all towers, in the line of the bridge, are inclined to the vertical 1 to 7, and are 5 m. (16.4 ft.) apart transversely at the top. The vertical sides are 15 m. (49.2 ft.) apart. Both sides are braced by horizontals and cross diagonals. At the feet of the towers, and in the planes of the abutments of the arch, no horizontal bracing is employed. Towers Nos. 2 and 7 are designed as anchorages; the top chords of the trusses, which are continuous through several spans, being firmly attached thereto. The posts over the arch rib lie in the same plane as the sides of the arch. They are braced transversely, and are capable of transmitting lateral forces from the bridge above through the system of wind-bracing just described.

The viaduct spans, 15, 30 and 40 m. long, have vertical trusses 6.0 m. (19.7 ft.) deep and 5 m (16.4 ft.) apart. They are divided into panels 7.5 m. (24.6 ft.) long by a single system of triangulation. The principal horizontal bracing is between the top chords, and is independent of the roadway construction. In the 30-m. and 45-m. spans the lower chords are, however, also braced horizontally. At the end panels the wind-strains are carried from the top chord to the towers by transverse bracing.

The posts carrying the trusses over the arch are so connected to the bottom chord of the bridge that it is free to move and that no uncertain strains may be transmitted at these joints.

The trusses are made continuous over the approach bents on both sides, and over the arch. They rest on rollers on the top of the bents and at the abutments, but are rigidly connected at bents 2 and 7 and at the crown of the arch. Over the inside faces of bents 4 and 5 provision is made for the expansion of the top chord by separating the adjoining ends.

The floor system is so constructed of beams and stringers that the strains due to applying the train brakes and other longitudinal strains are transmitted through the stringer lying directly over the top chord to the latter, while the horizontal strains pass through stringers and diagonals into the floor beams at the panel points, and are thence carried into the chord system. All material in the superstructure is basic steel, the aggregate weight being about 5,100 t. (5,622 tons).

The methods adopted in erecting the steel work are of particular interest. In a general way this work may be divided into the erection of (1) the towers and the viaduct trusses, and (2) the arch ribs and the trusses carried by them.

Previous to beginning erection the contractors built a very extensive plant for carrying on the work. On the Solingen side of the gorge, Fig. 2, was established a yard for storing material and for the various necessary shops and store houses, power plant, etc. From this yard a railway ran down into the gorge parallel with the bridge site. A similar railway extended up the opposite side of the gorge, and a temporary bridge spanned the river and bottom of the gorge between the two railways. Spur tracks from the railway lines handled material to the sites of the several abutments and tower foundations. These railways were operated by wire cables run by electric motors placed at the top of the gorge on each side, and getting their power from the central power plant. An electric lighting system, a telephone system, water supply pipes, etc., were constructed as shown by Fig. 2, which also explains the general method of erecting the superstructure.

To erect the viaduct towers a timber staging was carried up inside the steel work on which was mounted the necessary hoisting apparatus for handling the material. The viaduct spans at the extreme ends were erected by means of falseworks built up from the ground, and the intermediate spans by means of temporary staging trusses hung between the towers. These staging trusses or spans were first erected on the ground and then hoisted to the tops of the towers and hung from temporary cantilevers attached to the towers as shown by Fig. 3. Both the cantilevers and the staging span were made of steel, and upon them the permanent span was erected as it would be upon a falseworks resting on the ground. Altogether six spans of the viaduct were erected by this method.

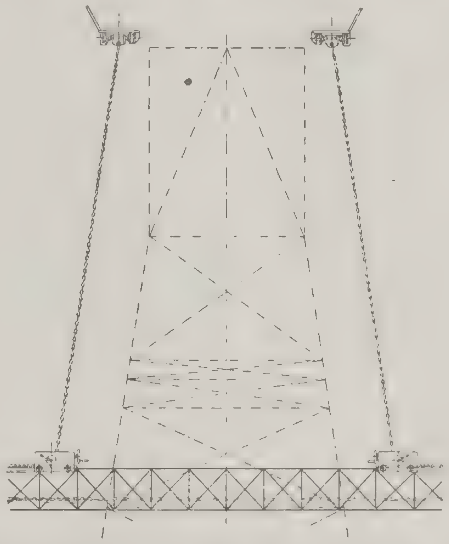

Fig. 6.—Traveling Inspection Staging for Arch Span; Muengsten Bridge.

The arch ribs and the truss spans supported by them were erected simultaneously. Referring to the elevation, Fig. 2, it will be seen that the extreme end towers were anchored by adjustable anchorages to the banks of the gorge. Between these two towers the trussed spans are continuous and serve as anchor rods. Therefore the truss span over the arch was built out as a cantilever as far as the first vertical. The arch ribs were also built out as cantilevers to the same point, when the anchor rod A B was attached as shown by Fig. 2. These anchor rods on each side held the arched structure until the closure at the center relieved them. Material was handled by revolving cranes running on top of the trussed spans. The temporary stagings for riveting are indicated by Fig. 2. The final adjustment was made by means of hydraulic jacks placed at the crown of the arch and at the upper arch chord abutment connection. This adjusting device at the abutment is shown by Fig. 4. Hydraulic jacks were also arranged to tighten or loosen the anchor cables.

One other feature of the construction which deserves to be noticed is the rather elaborate permanent constructions to be used in the future inspection, repairing and painting of the bridge. The general nature of these devices is shown by Figs. 5 and 6, Fig. 5 showing the traveling staging and ladder for examining both the exterior and the interior of the truss spans supported by the arch and the towers, and Fig. 6 the corresponding device for examining the metal work of the arch proper. For the truss spans two forms of travelers are employed, one running inside the trusses and the other outside, each being intended to reach the corresponding part of the metal work. Two of the outside travelers are employed, each having a range of travel of one-half the length of the bridge, but the one inside traveler is operated the whole length of the trussed structure. For the arch proper the traveler is simply a foot bridge suspended by chains from a carriage running on the bridge tracks. By means of windlasses these chains are shortened or lengthened so as to bring the foot bridge at the proper height for easy access to the intrados of the arch at any point in its length.

Construction was begun on the superstructure of the bridge in the spring of 1895 and the structure was completed ready for the passage of trains on July 3, 1897. Under a test load, consisting of three locomotives followed by 40 loaded cars on each track, the arch span showed a maximum depression of 15.4 mm. (0.616-in.). The cost of the bridge was 6,147,830 fr. ($1,230,000).

THE HIGHEST CHIMNEY IN AMERICA.*

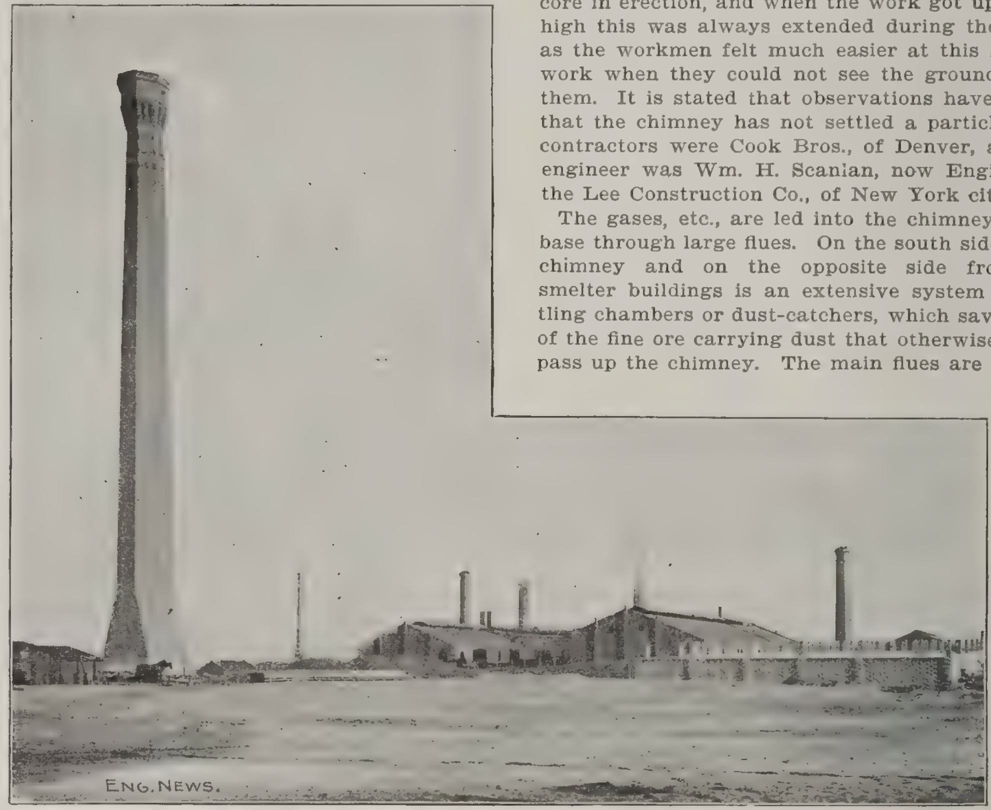
By W. P. Hardesty, C. E.

At Denver, Colo., is a brick chimney which is exceeded by but four in the world in height or size. This is the stack of the Omaha and Grant Smelter, which serves to carry away the poisonous fumes and gases generated in the process of smelting the precious ores at this extensive plant. The works here cover nearly 50 acres of ground, and before the panic of 1893 about 550 men were regularly employed. At present about 350 men are employed. After stacks of the ordinary size had been used for many years, it was decided that it would be better to erect one stack of great height, having sufficient size and draft to answer for all needs.

The present chimney has the following main dimensions: Height above the stone table at ground, 352 ft. 7 ins.; size at base, 33 ft. square; size at throat, 20 ft. in diameter; thickness of outer shell at base, 48½ ins.; at top, 13 ins.; thickness of core at base, 26 ins.; at top, 9 ins.; diameter flue, 16 ft.; foundation, 56 ft. square by 16 ft. deep.

In building, the ground was first excavated to the depth deemed sufficient, when about 2 ft. of water stood in the bottom. The material in the bottom was coarse sand. Then 8 ft. of cement concrete was put in, in which was placed a grillage of steel rails laid nearly together and crossing at right angles. These beams were used only in the masonry under and outside of the rings of masonry supporting the shell and core of the chimney. On top of the concrete was laid 8 ft. of brick work, stepped in about 1 in. at each course. On this was laid a stone footing 2 ft. thick, reaching above the ground level, and on this was built the chimney.

The shell or outer part of the chimney does not assume the regular octagon shape until 64 ft. high, the corner starting to batter off at about 25 ft. up. The exterior lines of the chimney are designed with an entastis or slight swelling, as shown. Two heavy systems of tie rods run through the chimney near its base in each direction. Where the main flue conveying the gases enters the chimney, an arch is sprung over the opening. The clearance between the flat sides of the shell and the outside of the core varies from over 2 ft. at the bottom to only 3 or 4 ins. at the top. At intervals along the sides are placed rollers to brace the core against the shell and to allow of the movement of the former in expansion. The expansion of the core when heated was estimated at about 4 ins. The draft to be expected under probable conditions as to temperature was taken to be equivalent to that caused by a pressure of 1-10 lb. per sq. ft.



THE HIGHEST CHIMNEY IN AMERICA.
Built for the Omaha & Grant Smelter, Denver, Colo. W. M. Scanlon, Architect; Cook Bros., Contractors.

The loads, etc., were taken as follows: Normal pressure on earth base, 3.2 tons per sq. ft.; total weight above foundation (on stone footing), 12,376,500 lbs.; pressure at base of shell, 148 lbs per sq. in.; at base of core, 160 lbs.; pressure on leeward side of base during a tornado, 295 lbs. per sq. in., and at windward side, 5 lbs., area exposed to wind pressure, 9,230 ft. Total wind pressure during a tornado, 369,200 lbs. Portland cement was used in the foundations, but above the larger part of the mortar was lime, and the proportion of lime was increased toward the top.

An average mixture was where a soft paste, made of about 2 bbls. of neat cement, would be added to and worked into a batch of lime mortar of about 6 times its volume, and then be hoisted to be used. All the bricks used were hard-pressed, from Golden, Colo. Push joints or shove joints were made in laying the brick, to secure the most compact work possible. At about 30 ft. below the top of the brick work, where the outer shell is but 13 ins. thick, the expansion for the cap begins. It swells out to a crown 5 ft. thick, and this was only done by using hoops and clamp rods built into the brick work to hold it together. The cast-iron cap weighs 22,000 lbs.

At intervals of 20 ft. in height, bands of 4-in. × ½-in. iron set vertically were built into the brickwork, four inches inside of the outer face.

An iron ladder is provided leading from the bottom of the space between the core and the shell to a trap door on top of the cast-iron cap.

The cast-iron cap has a lightning rod consisting of a ¾-in. galvanized wire rope securely fastened to it, the lower end of the conductor being fastened to an iron plate buried in the earth below the level of the ground water.

The following is a statement of the material actually used in the structure:

Brick	1,943,000
Lime, bushels	8,480
Portland cement.	Bbls.
1. In concrete	775
2. In stone work	26
3. In brick work	707
Total	1,508
Sand	2,331 cu. yds.
Railroad iron in concrete	48,960 lbs.
Beams under openings	2,574 "
Wrought-iron bands and rolls	23,180 "
C. I. plates and cap	56,474 "
Total	131,188 "

The chimney was built in 1892, the work being done in 120 days, and the total cost was $53,000. A scaffold was built up the interior of the flue or core in erection, and when the work got up pretty high this was always extended during the night, as the workmen felt much easier at this scaffold work when they could not see the ground below them. It is stated that observations have shown that the chimney has not settled a particle. The contractors were Cook Bros., of Denver, and the engineer was Wm. H. Scanlan, now Engineer of the Lee Construction Co., of New York city.

The gases, etc., are led into the chimney at the base through large flues. On the south side of the chimney and on the opposite side from the smelter buildings is an extensive system of settling chambers or dust-catchers, which save much of the fine ore carrying dust that otherwise would pass up the chimney. The main flues are 11 × 14 ft. There are altogether about two miles of flues and underground passages leading to the chimney from all parts of the plant, and the connections are such that all the smoke and gases from all the operations can be conducted to the one chimney.

STATISTICS OF RAILWAYS IN THE UNITED STATES FOR THE YEAR ENDING JUNE 30, 1898.

The statistician of the Interstate Commerce Commission, Prof. Henry C. Adams, has furnished to the press an advance abstract of the forthcoming tenth annual report of the commission, and from it we take the following figures of principal interest to our readers:

Mileage.—The total railway mileage in the United States on June 30, 1897, was 184,428.47 miles, there being an increase of 1,651.84 miles, or 0.91% during the year. In round numbers, Alabama shows an increase of 117 miles; Arkansas, 192 miles; California, 219 miles; Louisiana, 161 miles, and Michigan, 123 miles. The increase in mileage in the other states and territories in which an increase occurred was less than 100 miles. In a few states, as usual, a decrease in mileage is shown. The aggregate length of railway mileage, including all tracks, on June 30, 1897, was 243,444.41, the increase being 3,315.29 miles. The length of second track was 11,018.47 miles; of third track, 995.79 miles; of fourth track, 780.48 miles. The mileage of yard track and sidings amounted to 46,221.20 miles. Excepting yard track and sidings, about 32% of which are laid with iron rails, substantially 95% of the railway tracks in the country are laid with steel rails.

Equipment.—The total number of locomotives in service on June 30, 1897, was 35,986, the increase in number as compared with the preceding year being 36. Of this number, 10,017 were passenger locomotives; 20,398 freight locomotives, and 5,102 switching locomotives. The number of locomotives not classified was 469. The total number of cars of all classes reported in service on the date named was 1,297,480. The corresponding number for the previous year was 169 greater. Of these cars, 33,626, or 623 more than for 1896, were assigned to the passenger service; 1,221,730 were assigned to freight service, indicating a decrease of 157 during the year; and 42,124 were assigned to the special service of the railway companies.

---

*The four chimneys which exceed the Omaha and Grant chimney in height, according to Kent's "Pocket-Book for Mechanical Engineers," are at Hutte, Saxony, 460 ft.; two at Glasgow, Scotland, 454 and 435 ft.; and Bolton, England, 367½ ft.

During the year ending June 30, 1897, the railways in the United States used 20 locomotives and 708 cars per 100 miles of line. Taking the United States as a whole, 48,861 passengers were carried and 1,223,614 passenger-miles accomplished per passenger locomotive, and there were 36,362 tons carried and 4,664,135 ton-miles accomplished per freight locomotive. All of these items show a decrease as compared with those of the preceding year. The number of passenger cars per 1,000,000 passengers carried during the year under consideration was 69, and the number of freight cars per 1,000,000 tons of freight carried was 1,647. It should be understood, however, that this average does not include such cars, mainly in the freight service, as are owned by private parties, for the use of which the railways paid during the year approximately $11,000,000. Including in the term equipment both locomotives and cars, it is found that the total equipment of railways on June 30, 1897, was 1,333,466. These figures are 133 less than on June 30, 1896.

Of this total number 525,286 were fitted with train brakes, the increase being 76,432; and 678,725 were fitted with automatic couplers, the increase in this case being 133,142. These increases are somewhat smaller than the corresponding increases for 1896. It should be noted, however, that the number representing the increase in equipment in that year was over 27,000. Further details as to equipment on June 30, 1897, show that the number of passenger locomotives fitted with train brakes was 9,899, or 83 more than the preceding year. The number of freight locomotives so fitted was 18,796, or 875 more than the preceding year. The number of switching locomotives fitted with train brakes was 3,666. The number of passenger locomotives fitted with automatic couplers was 4,687, the increase with respect to 1896 being 184. The number of freight locomotives fitted with automatic couplers was 4,192, the increase being 819. The number of switching locomotives fitted with such couplers was 741, or 147 more than for 1896. The number of passenger cars fitted with train brakes on June 30, 1897, was 33,078, and the number fitted with automatic couplers was 32,661, the increase in the one case being 665 and in the other 815. The number of cars in freight service fitted with train brakes was 453,688, or 74,630 more than on June 30 of the previous year. The number fitted with automatic couplers was 629,399, indicating an increase of 129,166. Of the total cars in service 492,559, on June 30, 1897, were fitted with train brakes, and 668,937 were fitted with automatic couplers, the increase for the year in the former case being 75,237; in the latter, 131,989.

Employees.—The number of men employed by the railways of the United States on June 30, 1897, as reported, was 823,476, or 449 men per 100 miles of line. The corresponding figures for the year ending June 30, 1896, were slightly larger. Regarding the year ending June 30, 1897, it appears that the aggregate amount of wages and salaries paid employees was $465,601,581. This amount represents 61.87% of the total operating expenses of railways, or $2,540 per mile of line. The total compensation for 1896 was $3,222,950 greater.

Capitalization and Valuation.—On June 30, 1897, the amount of railway capital outstanding was $10,635,008,074, which, assigned on a mileage basis, shows a capital of $59,620 per mile of line. The amount of capital stock was $5,364,642,255, of which $4,367,056,657 was common stock, and $997,585,598 preferred stock. The amount of funded debt was $5,270,365,819. The classification of funded debt shows that it consists of mortgage bonds, $4,539,911,595; miscellaneous obligations, $430,718,303; income bonds, $259,847,154, and equipment trust obligations, $39,888,767. The amount of capital stock paying no dividend was $3,761,092,277, or 70.10% of the total amount outstanding. The amount of funded debt, excluding equipment trust obligations, which paid no interest was $867,950,840. Of the stock paying dividends, 5.37% of the total stock outstanding paid from 1 to 4%, 6.53% outstanding paid from 4 to 5%, 5.99% outstanding from 5 to 6%, 3.58% outstanding from 6 to 7%, and 4.62% outstanding from 7 to 8%. The total amount of dividends was $87,110,599, which would be produced by an average rate of 5.43% on the amount of stock on which some dividend was declared. The amount of mortgage bonds paying no interest was $615,259,989, or 13.55%; of miscellaneous obligations, $37,345,879, or 8.67%, and income bonds, $215,344,972, or 82.87%. The amount of current liabilities outstanding on June 30, 1897, was $578,501,635, or $3,156 per mile of line.

Public Service.—The number of passengers carried during the year was 489,445,198, there being a decrease of 22,327,539 as compared with 1896. The number of passengers carried one mile during the year was 12,256,939,647, a decrease of 792,067,586 being shown in this item as compared with 1896. The number of passengers carried one mile per mile of line was 66,874, a decrease of 4,831. The number of tons of freight carried during the year was 741,705,946, 24,185,439 less than for 1896. The number of tons of freight carried one mile was 95,139,022,225, a decrease of 189,338,053. The number of tons of freight carried one mile per mile of line was 519,070, 4,753 less than for the preceding year.

Earnings and Expenses.—The gross earnings of the railways of the United States for the year ending June 30, 1897, as reported for an operated mileage of 183,284.25, were $1,122,089,773, a decrease of $28,079,603 for 1896. The expenses of operation for the year were $752,524,764. This amount is $20,464,280 smaller than for the year 1896, the operated mileage for that year being 181,982.64 miles. The operating expenses of 1897 were distributed as follows: Maintenance of way and structures, $159,434,403, decrease as compared with the preceding year, $910,547; maintenance of equipment, $122,762,358, decrease, $10,619,640; conducting transportation, $432,525,862, decrease, $9,691,720; general expenses, $36,481,269, increase, $397,984. Gross earnings per mile of line operated averaged $6,122; operating expenses, $4,106. These amounts are, respectively, $198 and $142 less than the averages for 1896.

Accidents.—The total number of casualties to persons on account of railway accidents for the year ending June 30, 1897, was 43,168. Of these casualties 6,437 resulted in death, and 36,731 in injuries of varying character. Of railway employees, 1,693 were killed and 27,667 were injured during the year. The casualties to employees resulting from coupling and uncoupling cars were, killed, 214; injured, 6,283. The corresponding figures for the year ending June 30, 1896, were 229 killed and 8,457 injured. The total number of passengers killed during the year under review was 222, injured 2,795. From summaries showing the ratio of casualties, it appears that 1 out of every 486 employees was killed and 1 out of every 30 employees was injured during the year. One passenger was killed for every 2,204,708 carried, and 1 injured for every 175,115 carried. Basing ratios upon the number of miles traveled, it appears that 55,211,440 passenger-miles were accomplished for each passenger killed, and 4,385,309 passenger-miles for each passenger injured.

HEAVY CONSOLIDATION LOCOMOTIVES FOR THE BURLINGTON & MISSOURI RIVER R. R.

One of the marked features of modern motive power equipment is the great increase in the size, weight and power of freight engines, in order to secure the economic advantages which result from an increase in the train loads hauled. We have already had occasion to illustrate and describe some of these large and powerful engines, and we are now able to give particulars of other engines which are illustrative of the present tendency towards heavy train loads.

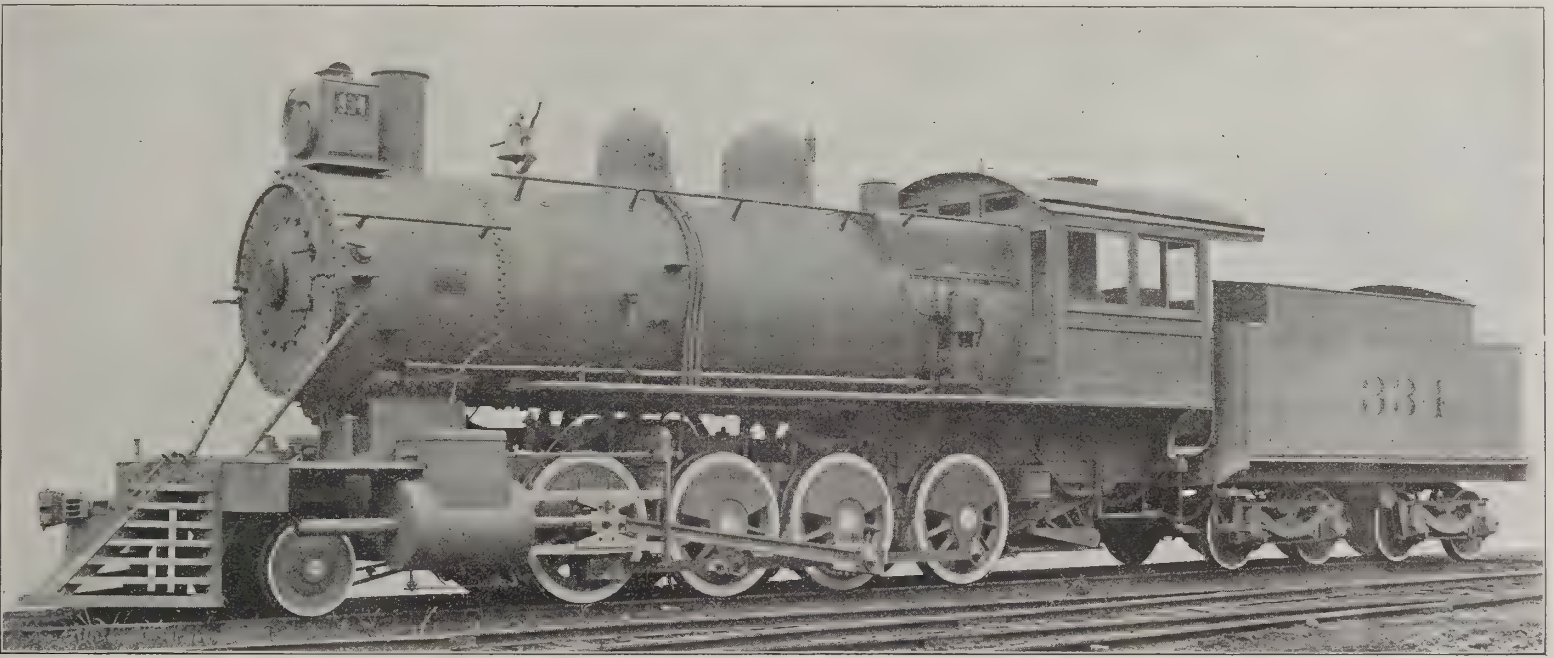


Fig. 1.—CONSOLIDATION FREIGHT LOCOMOTIVE; BURLINGTON & MISSOURI RIVER R. R.
Pittsburg Locomotive Works, Builders.

The locomotives referred to are four consolidation engines, with 166,000 lbs. on the driving wheels, intended for regular freight train service on the Black Hills division of the Burlington & Missouri River R. R. (Burlington system), between Edgemont and Deadwood, So. Dak., a distance of 107 miles. The track has the standard gage of 4 ft. 8½ ins. The maximum grades are 2% against northbound traffic and 3% against southbound traffic. The minimum curvature is 16°, and most of the curves are under 10°. all having spiral transition curves, and being equated for the grades. Mr. T. E. Calvert, General Superintendent of the B. & M. R. R. R., informs us that the slow freight trains usually make the trip in ten hours, the load behind the tender being about 330 tons northbound and 200 tons southbound. The new engines are intended to haul 15 cars where the present engines haul 10 cars. As the weak point of the present engines is in their boilers, the new engines have boilers of specially large capacity. The following table gives the comparative dimensions of the old and new engines:

	Old engines.	New engines.
Driving wheels	3 ft. 8 ins.	4 ft. 4 ins.
Weight on driving wheels	101.820 lbs.	166,000 lbs.
Weight, total	118,310 "	181,200 "
Cylinders	20 × 24 ins.	22 × 28 ins.
Boiler pressure	160 lbs.	180 lbs.

The engine has a compact and powerful appearance, with the extreme simplicity of finish which is characteristic of modern locomotives. It has a Belpaire boiler of somewhat unusual design, the shell at the firebox having convex sides swelling to a width greater than that of the flat top of the boiler sheet, so that there is a peculiar reversed curve connection between the vertical sides of the flat boiler head and the convex sides of the shell. This is somewhat similar to the boilers of the class HH consolidation engines of the Pennsylvania R. R., but in general boilers of this type have a more symmetrical arrangement of the side and top plates of the shell. Another special feature is the use of a boiler jacket of cold-rolled pickled steel, painted black, instead of the planished iron jacket which has for so long been characteristic of American locomotives, but which is now gradually giving place to a more economical form of covering. The lagging is of asbestos.

The fuel used will be bituminous coal. The firebox has a brick arch, supported on studs, and has cast iron grates of the railway company's standard pattern. The dome and sandbox are on the boiler barrel, the former having the whistle attachment in the side, and the latter being fitted with the Leach air-jet sanding device. It has also a pneumatic blow-off cock and bell ringer. A special fitting on the boiler heads carries the safety valves. The smokestack is of the bootleg or tapering pattern, with its narrowest part just above the smoke-box.

The driving wheels have cast-iron centers, and all have flanged tires. This is a somewhat notable departure from regular practice, and will be observed with interest in view of the character of the line on which the engines are to run. It is more or less of an experiment. To partially overcome the crowding against the rail, the flanges of the forward and rear driving wheels are turned down 1-16-in. below the M. C. B. standard, making the flange 1 3-16 ins. instead of 1¼ ins. The second and third pairs of driving wheels have flanges of the standard dimensions. All the driving wheels are set ⅛-in. closer together than in regular practice, the distance between backs of wheels being 4 ft. 5¼ ins. instead of 4 ft. 5⅜ ins. The pistons are of cast steel, fitted with the Dunbar packing, and have 4-in. steel piston rods. The slide valves are of the Richardson balanced pattern.

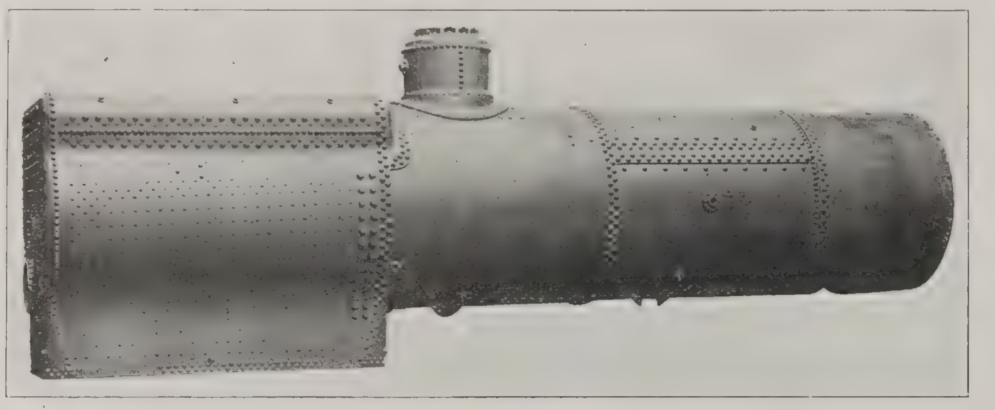

Fig. 2.—BELPAIRE BOILER FOR CONSOLIDATION LOCOMOTIVE; BURLINGTON & MISSOURI RIVER R. R.

The pilot is of wood, with a vertical projecting nose, reinforced by steel plates, and the point is supported by tie-rods from the bumper beam. Automatic M. C. B. coupler heads are fitted to the pilot and tender drawbars, and that of the latter has a swinging head and fixed knuckle. The tender is of the hopper type, built to the railway company's standards, and has semi-elliptic truck springs. The tank is 19 ft. long and 9 ft. 6 ins. wide, the length of tender frame being 32 ft. 3½ ins.

Fig. 1 is a general view of the engine, and Fig. 2 is a view of the boiler, showing the heavy character of its construction and the special features of the design.

The four engines were designed and built by the Pittsburg Locomotive Works, Pittsburg, Pa., under the general direction of Mr. G. W. Rhodes, Superintendent of Motive Power of the Chicago, Burlington & Quincy R. R., which system comprises the B. & M. R. R. R. Mr. D. Hawksworth is superintendent of motive power of the latter road.

The leading dimensions and particulars of these engines are as follows:

Heavy Consolidated Freight Locomotive; Burlington & Missouri River R. R.

Running Gear:	
Driving wheels, 8; diameter	4 ft. 4 ins.
Truck wheels, 2; diameter	2 " 6 "
Tender wheels, 8; diameter	3 " 1 "
Driving wheel centers	Cast-iron.
Truck and tender wheels	Chilled cast-iron.
How are driving-wheel tires secured?	By shrinkage.
Engine truck, swing center; journals, drvg axles	9 × 10 ins.
Wheelbase.—Driving	15 ft. 0 ins.
Total engine	23 " 6 "
Engine and tender	53 " 2 "
Truck axle to leading driving axle, c. to c.	8 " 6 "
Wheels having blind tires	None.
Weight in Working Order:	
On driving wheels	166,000 lbs.
On truck wheels	15,200 "
Engine, total	181,200 "
Tender, empty ..35,000 lbs.; loaded	94,200 "
Water in tank	41,700 "
Coal on tender	17,500 "
Does counterbalance conform to M. M. Assoc. rules?	Yes.
Cylinders	22 × 28 ins.
Form of crosshead and guides	Alligator.
Connecting rod, length between centers	10 ft. ¾-in.
Slide rod	Strap and forked ends.
Valve Gear.—Type	Stephenson link.
Ports, steam. .1¼ × 18⅞ ins.; Ports, exhaust.	3 × 18⅞ ins.
Eccentrics, throw	2½ "
Slide valves, style	Richardson balanced.
" maximum travel	5 ins.
" outside lap.	¾-in.
Boiler.—Type	Belpaire.
Diameter, barrel, inside smallest ring	6 ft. 2 ins.
Barrel plates........⅝-in.; Smokebox tube-plate.	½-in.
Horizontal and circumferential seams	Double riveted.
Joints	Butt, with inside and outside welt.
Rivets.	⅞-in.
Height from rail to center line	8 ft. 9⅝ ins.
Length of smokebox, including extension	5 "11⅞ "
Spark arresting device	Netting, mesh 2 × 2 "
Injectors, two	"Monitor" and "Friedman."
Working steam pressure	180 lbs.
Firebox.—Type	Belpaire.
Length, inside	9 ft. 5¾ ins.
Width, inside, at top, 5 ft.; at bottom	3 " 4 "
Depth, front 5 ft. 11⅞ ins.; at back	5 " 8¾ "
Side plates..........⅜-in.; back plates	⅜ in.
Crown plates........⅜-in.; tube plate	½-in.
Crown stays	Radial, 1⅛ ins.
Is firebrick arch used?	Yes.
Stay bolts (drilled) diameter, ⅞-in.; pitch	4 and 4½ ins.
Water spaces, width at front, back and sides	4 "
Tubes.—Number	292
Diameter, outside	2¼ ins.
Length over tube plates	14 ft. 6½ "
Heating Surface and Grate Area:	
Heating surface, tubes (interior area)	2,486.4 sq. ft.
" firebox, incldg brick arch t'bs	188.6 "
" total	2,675.0 "
Grate area	31.6 "
Miscellaneous:	
Exhaust nozzle, single, diameter	5, 5¼ and 5½ ins.
Exhaust nozzle, distance below center line of boiler	4 "
Smokestack, diameter at top 17 ins.; at base	16¼ "
" height above smokebox	3 ft.
" height of top above rail.	15 "
Capacity of tender tank	5,000 gallons.
Capacity of coal space	17,500 lbs.
Brake fittings	Westinghouse-American.

* * *

ANNUAL MEETING OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The 50th meeting of this Association was held in Boston during the week beginning Aug. 22. During the same week, or in the latter half of the week preceding, there were held meetings of several affiliated societies, as follows: American Forestry Association, Aug. 23 and 24; Geological Society of America, Aug. 23; American Chemical Society, Aug. 22 and 23; Society for the Promotion of Agricultural Science, Aug. 19 and 20; Association of Economic Entomologists, Aug. 19 and 20; American Mathematical Society, Aug. 19 and 20; Society for the Promotion of Engineering Education, Aug. 18, 19 and 20; American Folk-Lore Society, Aug. 25; National Geographic Society, Aug. 25; Botanical Society of America, Aug. 19 and 20; Conference of Astronomers and Physicists, Aug. 18 to 20.

The meeting of the American Association for the Advancement of Science was the largest it has ever held with three exceptions—Boston, 1880; Montreal, 1883, and Philadelphia, 1884. The meetings of 1883 and 1884 were enlarged by the presence of many members of the British Association. The Boston meeting of 1880 registered 998 members as present, and that of 1898 only 903. The evident decline in membership and in interest in the Association during the last 18 years is due to the growth of the affiliated societies of specialists, which have in most cases originated in the sections of the Association. By the scheme of having these societies meet at the same place and time each year they are practically the same as sections of the parent association. In fact some of these societies joined with the sections in holding their meetings. While the registered list of members present at the Boston meeting has been three times exceeded, there is no doubt that if the members of the affiliated societies who attended their several meetings but who are not members of the Association were counted, it would be found that in the week of Aug. 22-27 in Boston, there was the largest gathering of scientific men ever known in this country.

The meetings, both of the American Association and of the affiliated societies, were highly successful, both in the numbers of papers presented and in the attendance at the several sessions. Some idea of the vast amount of work done in the sections of the Association is given by the following list of the sections and the number of papers presented in each. Section A, Mathematics and Astronomy, 39 papers; B, Physics, 52; C, Chemistry; D, Mechanical Science and Engineering, 89; E, Geology and Geography, 27; F, Zoology, 35; G. Botany, 56; H, Anthropology, 55; I, Social and Economic Science, 29.

The following are abstracts of the most important papers presented in Section D.

A Combination Absorption and Transmission Dynamometer for Laboratory Purposes.

By John Joseph Flather, Minneapolis, Minn., Professor of Mechanical Engineering, University of Minnesota.

This paper describes some recent improvements in Prof. Flather's hydraulic transmission dynamometer, the most notable feature being the employment of a water-cooled pulley and a perforated rim which permits the use of a brake band that can be used for absorbing the power furnished to the machine. The fixed pulley which is ordinarily used to connect the dynamometer to the machine to be driven has internal flanges for carrying the cooling water and the rim is furnished with a number of brass bushings drilled through endwise, and provided with a regulating screw by which the amount of water admitted to the brake is readily controlled. The brake band is a three-ply cotton belt 7 ins. wide, connected through two sets of tension springs to the brake regulating screw.

The brake band may be quickly removed, thus converting the machine into a regular transmission dynamometer. In either case an automatic record is obtained on a roll of paper which is caused to pass with uniform motion under an indicator pencil that records variations of pressure.

In addition to the force curve traced by the indicator pencil the zero or datum line is traced by another pencil which is adjustable in position and may be located at pleasure on a line parallel with the axis of the shaft. Thus one is enabled to measure the total power required to run a given machine or any subdivided part of it. The two cylinders through which the driving power is transmitted are each 10 sq. ins. in area and are provided with bronze pistons actuated by plunger pins which may be located in either of two positions—the inner for ordinary work and the outer for extra heavy work, say when it is required to measure 20 HP., or when the speed of rotation is very slow. Springs of varying degrees of intensity may be used to transmit the pressure from shaft to indicator pencil. These springs are changed as in any ordinary indicator.

The work of friction of the plunger in the cylinder is practically eliminated, since the combined area of the plungers is so much greater than in the indicator piston; and since the indicator motion multiplies the distance moved by the indicator piston five times, it will be seen that the motion of the plungers is exceedingly small. The more recent machines are provided with adjustable casters which permit the weight of the dynamometer to be carried by wheels or to rest firmly on the floor, as desired.

High Speed Influence Machines.

By Charles F. Warner, Cambridge, Mass.

The causes of the electro-motive force in influence machines, their reversals and certain other peculiarities are not known; hence improvements have been effected by purely experimental means. A reference to some properties of earlier machines is made and to recent improvements under patents by Waite, Myers and Rose, Holopeter and Elihu Thompson.

The special improvements which it is the main purpose of this paper to recount are effected by special insulation, improved contacts, careful balancing of revolving parts, and peculiar driving mechanism. The inconvenience from reversals is largely overcome by a newly devised commutator. In order to provide for discharges of great frequency, such as are required, for example, to produce the Rontgen rays effectively, the principal aim has been to secure high speed with ease and safety. Two forms have resulted. One, designed for compactness, has ball bearings. The other of larger dimensions has gear metal bearings. The speed attained exceeds 4,000 revolutions per minute, which is the highest rate the author has been able to find recorded for influence machines. The regulating discharges are of great frequency and, for certain purposes, are remarkably efficient.

Instruments and Methods of Hydrographic Measurements Used by the United States Geological Survey.

By F. H. Newell.

By the organic law creating the Geological Survey, the Director is charged with the duty of the classification of the public lands and examination of the geological structure, mineral resources and products of the national domain. Under this general law extensive surveys have been carried on through nearly 19 years. It has been found that throughout a great part of the country the most valuable of the natural resources is the water. Especially is this true of the western half of the United States where all land values rest upon questions of water supply. The subject of the hydrography of the country was thus early forced upon the attention of the topographers and geologists of the survey and a large amount of information collected as incidental to other work. In 1888 the division of hydrography was created, systematizing the observations and data bearing upon the water resources, and examinations were begun of the distribution and fluctuations of waters above and under ground. The methods employed have resulted from many years of experience and are of such a character as to obtain the desired information with an accuracy consistent with a fair degree of scientific value and yet with full consideration of the expenditure available.

In the measurement of various streams, especially of the larger rivers, it has been found desirable to seek a locality where the bed and banks are fairly stable and the velocity of the water moderate. The width and depth have been obtained by direct measurements and the rate of flow determined at various points in the cross-section by means of various forms of current meters. Computations based upon the slope and other factors have been made in a few instances but mainly as a matter of curiosity to note the possible accordance with the results of detailed current meter measurements. Estimates of the flow over weirs or dams have been had occasionally, but the uncertainties involved in the leakage and discharge through gates, water wheels, etc., have been so great that little reliance has been placed upon these computations. The great bulk of the data has been derived from computations based upon the direct measurement of velocities throughout the cross-section of a stream when standing at various heights.

At the selected points, daily observations of the height of water are made, and by means of these and the occasional discharge measurements, computations are made of the daily discharge. Graphic diagrams are then constructed and averages drawn for the month, the results being expressed in cubic feet per second or in depth in inches of the run-off from the entire drainage basin. The diagrams afford a means of comparing the regimen of one river with another and of noting fluctuations day by day or year by year.

Evaporation and Seepage from Reservoirs and Rivers.

By Prof. L. G. Carpenter, Fort Collins, Colo.

From two seasons' measurements on a series of reservoirs in Colorado, the author determines that in those cases the loss from seepage is much less than from evaporation, amounting to about 2 ft. in depth per annum. Eleven years' determination of evaporation shows the loss from that source to be 41 ins. from his standard tank. From the reservoirs under observation, several years' record indicates a loss of about 60 ins. from evaporation.

(This is printed as Bulletin No. 45, Colo. Agr'l Experiment Station.)

The author reports also the results of a series of measurements made on a number of rivers in Colorado. Two measurements were made on the Rio Grande del Norte over a stretch of 80 miles; fourteen measurements on the Cache a la Poudre for 40 miles; one on the Arkansas for 200 miles; one on 40 miles of the Big Thompson; seven on the South Platte for 150 miles; a distance of over 2,000 miles gone over in detail, and on which all water taken out by ditches or entering through tributaries was measured.

While gain from seepage is the rule, there are sections on nearly all of these streams where losses are found year after year, and sometimes to a considerable extent.

The Rio Grande loses from 70 to 100 cu. ft. per second in a distance of 10 miles. On the other streams the loss is less. In the case of the Platte there is some reason to think that a portion of the water reappears. In the case of the Rio Grande, neither the water thus disappearing from the river, or the water sinking in the numerous small streams reappear within Colorado.

Energy Received from the Sun.

By Prof. L. G. Carpenter, Fort Collins, Colo.

It is well known that the sunshine on our Western plains is much greater in amount than that received by the East. For nearly ten years the author has maintained observations on the intensity of the energy received from the sun (using the Arago-Davy conjugate thermometers) and also observations on the amount of sunshine. The observations show an intensity of from 7 to 17 calories per sq. m. from 8 a. m. on sunny days, or from ½ to ¼-HP. per sq. yd. It seems as reliable as the wind, which is extensively used as a source of power for small plants.

On the Testing of Steam Pipe Covers.

By Prof. Charles L. Norton, Boston.

The manifest economy attendant upon the use of some sort of a non-conducting cover to prevent loss of heat from a hot steam pipe has led to many tests of the relative efficiency of materials in use for this purpose. There is a considerable discrepancy between the reported tests upon the efficiency of the materials in most common use, and there are some new materials used for this purpose. The facts seemed to warrant further investigation of the subject.

A series of tests has been made by means of an apparatus devised by the writer. A piece of steam pipe was heated electrically by means of a coil of wire in oil within the pipe. The amount of energy necessary to keep the pipe at a definite temperature is measured. Since the energy supplied is just sufficient to keep the pipe at a constant temperature it is therefore just equal to the energy lost by the pipe. Hence from the electrical energy supplied we may compute the heat lost from the outside of the pipe. The economy of the use of some of the better covers is computed, and an examination of the fire resisting properties of the several covers is made. (Another report of these tests was given by Prof. Norton in a paper before the American Society of Mechanical Engineers at the Niagara Falls meeting in May last.—Ed.)

Methods of Determining the Frequency of Alternating Currents.

By Carl Kinsley, Instructor of Physics and Electrical Engineering, Washington University, St. Louis, Mo.

The accurate determination of the frequency is essential for the correct computation of the relations between electromotive force, current, self-induction and capacity. Since the periodicity must usually be squared, it is essential that the determination be made quickly and with but little error.

Dr. John Hopkinson was the first to use a stretched steel wire actuated by an electro-magnet and when the condition of maximum resonance was found, the periodicity was calculated from the constants of the wire and its tension.

Dr. Campbell (Phil. Mag., Aug., 1896) proposed the use of an iron rod which was thrown into resonance in the same way. From the constants of the rod and its length the periodicity was computed. The rod he found could be more easily used than the wire.

Another method capable of great accuracy and easy manipulation includes the use of a telephone in the alternating current circuit and a resonance tube by means of which the periodicity may be calculated from equations, or it can be gathered from tables already computed. (Kinsley, Phil. Mag., April, 1898.)

A very satisfactory method will be one which includes the use of a metal strip as the primary resonator whose periodicity may be changed by means of an added weight. An electro-magnet may be used as in the first two cases to set this into vibration. The periodicity can be calculated from the constants of the vibrator (Lord Raleigh, "Theory of Sound"), or a complete calibration can be made by two determinations. It will usually be more satisfactory to standardize by actually determining the periodicity of two adjustments of the resonator. The equation to be used for that purpose is

$$t^2 = Dl^3 M + Kl^4, \text{ when}$$

t = time of one complete oscillation.
l = distance of the sliding weight from the support.
M = mass of the slider.
$l,$ = length of the vibrating rod.
D and K are the constants of this particular apparatus which may be either calculated or obtained by experiment.

The condition of resonance is obtained with great readiness and the determination may be made with as great accuracy as may be desired.

MEETING OF THE AMERICAN SECTION OF THE INTERNATIONAL ASSOCIATION FOR TESTING MATERIALS.

The first annual meeting of the American Section of the International Association for Testing Materials was held at the Engineers' Club, of Philadelphia, on Aug. 27, with Prof. Mansfield Merriman in the chair. The first business of the meeting was the consideration of the proposed by-laws of the American Section. Mr. Gus. C. Henning explained that these by-laws were to be supplemental to the general laws of the International Association and were intended solely for government of what formed one section of the Association. The by-laws as adopted, after a careful consideration of each paragraph, were as follows:

(1) The name of this organization shall be the "American Section of the International Association for Testing Materials."

(2) The objects of the American Section shall be to unite more closely those members of the International Association living on the western continent, and to co-operate in the promotion of the purposes of this Association.

(3) Each member shall pay on the first of ——— of each year, to the Treasurer of the American Section, the sum of $2.50, annual dues for the current year. Of this amount, $1.50 shall be transmitted to the International Association, by the Secretary of the American Section, and the remainder shall be used to defray the expenses of the American Section. Any member of the American Section whose dues shall remain unpaid for the period of one year shall be reported to the Council of the International Association.

(4) The Officers of the American Section shall be, a Chairman, Vice-Chairman, Secretary and Treasurer, constituting the Executive Committee, and two members of the International Advisory Board. The American member of Council of the International Association shall be ex-officio a member of the Executive Committee. The officers of the American Section shall be elected at annual meetings and shall serve for two years.

(5) The American Section shall meet annually. The time and place of each meeting shall be fixed by the Executive Committee. Special meetings shall be called whenever the Executive Committee shall deem it necessary.

Next in order was the consideration of the problems outlined by the International Association. These problems, which are to be investigated by the International committees, and the American members who will act upon these committees, are as follows:

1. "Taking as a basis the existing conditions of inspection, to establish uniform International rules for the testing and inspection of all kinds of iron and steel." Two members to be appointed.

2. "Determinations of methods of test of the homogeneity of iron and steel with the object of eventually employing these methods for inspection." Booth, Garrett & Blair, Gus. C. Henning, Prof. Thomas Gray, Paul Kreuzpointner, A. A. Stevenson, William R. Webster.

"Preparation of uniform methods for the test of paints used for protection against corrosion of railroad structures." H. B. Seaman, J. A. L. Waddell, and two members still to be appointed.

3. "Unification of methods of test of tile pipe." One member to be appointed.

"Supplemental to the solution of the question of standard consistency of standard mortars. Determination of conditions which will produce approximately similar densities in tension and in compression briquettes." Richard L. Humphrey.

4. "Investigation of the behavior of soft steel under abnormally low temperatures." Prof. George W. Bissell.

5. "Methods of tests of welds and weldability." One member to be appointed.

7. "Collections of masses of material for the preparation of standard piece tests, with special reference to axles, tires, springs (car), cast and wrought-iron pipes, as well as the separate parts of structures." One member to be appointed.

10. "Investigations of the most practical methods of polishing and etching for microscopic study of wrought iron." Albert Sauveur.

11 and 12. "Study of the relation of chemical composition to weathering qualities of building stones. Study of the effect of the gases of combustion, especially sulphurous acid. One member to be appointed.

"Study of the relation of chemical composition to weathering qualities of roofing slates." Prof. Mansfield Merriman.

14. "Determination of rapid methods for determining conditions of constancy of volume of hydraulic bond materials." Richard L. Humphrey, William M. Maclay.

15. "In what manner can hydraulic bond materials be tested for tensile strength in the shortest period of time?" William W. Maclay, Dr. Charles F. McKenna.

16. "Testing and evaluating the resolutions of the conferences relating to the determination of adhesion of hydraulic bond materials." Booth, Garrett & Blair and one member still to be appointed.

17. "Examination of propositions for the uniform determination of the value of puzzolanas as mortars." Two members to be appointed.

19. "Investigation of the effect of fecal matter on the strength of hydraulic bond materials." Two members to be appointed.

18. "Investigations of the causes of abnormal behavior of cements as to time of setting." Two members to be appointed.

22. "How can the inspection of lumber assure protection against the growth of fungi (merulius lacrymans)?" Prof. John B. Johnson.

23. "Determinations of fundamental methods for testing lubricants (oils)." One member to be appointed.

"American Committee to report to the American Section on the present state of knowledge of impact tests." Prof. W. K. Hatt, Chairman; Prof. Edgar Marburg, James Howard.

These problems were taken up one at a time by the members and discussed in a general way. Mr. Henning first outlined the process to be followed by the committees having the problems in charge. Each committee would first investigate the problem assigned to it, and then it would be presented to the Section, and finally by that body referred to the council. If agreeable the report would then be considered in a general congress. To make the work of the most value it should be apportioned according to the desires and capabilities of the members, care being taken not to duplicate work already done. Problem 7, he stated, would require a careful study of what has been done in this country.

Mr. M. White, who has charge of the Physical Laboratory of the Bethlehem Iron Works, and was suggested as a member of this committee to consider Problem 7, stated that as the work of his company was practically all done under special government specifications, limited by government inspection, it seemed to him advisable to appoint some one from a company doing a more commercial business. In discussing this, Mr. Henning pointed out that following the first meeting of the International Association, held in Switzerland, at which Capt. Carter, U. S. A., was present, the United States government had revised its specifications and had translated, printed and distributed copies of the "Resolution of Conferences" of that and previous meeting to all its officers engaged in constructional work or testing. He had no doubt but that if properly presented and sufficiently urged by the Bethlehem Co. the government would make other changes.

In regard to Problem 17 it was decided that as the International Association had not included artificial cements it would be just as well to consider this as not including sag cements. Referring to Problem 18, Mr. Henning pointed out that this was a problem of special interest to foreigners alone, and could be abandoned by the American Section, since so few sewers were constructed in this country out of concrete.

The other problems were read by title only, and it was suggested that there might be other practical problems which could and should be considered by the Section. If these were of general interest they could be brought to the attention of the International Association; if of local interest, they could be investigated separately by the American Section. At any time, however, inquiries could be transmitted abroad to obtain the benefit of foreign investigation, and the members should have no hesitancy in doing this or in suggesting problems for consideration.

Dr. R. G. G. Moldenke thought that the list should include a problem dealing with the qualities and properties of cast iron. Our knowledge of cast iron, he stated, stood now about where our knowledge of steel was 15 years ago, and it was time something was determined definitely. Later Mr. Moldenke's suggestion was put in form and adopted.

By way of explanation Mr. Henning stated that there would be three editions of "Materials of Construction," the official organ, published in English, French and German. In each one of these editions the contributed articles would be in the language in which it was originally written to insure accuracy and to preserve the original expression of the author. Other matter would be in English, French or German, according to the edition. Any American member desiring to contribute could do so, and his papers, if carefuly prepared, would be welcomed by the editors of the journal.

Mr. Henning also suggested that as no problem including an examination and study of impact testing machines and impact testing had been included, it should be done, and he stated that this test was used to a large extent and very successfully abroad; but that in this country it was in a very crude state, and very infrequently employed. Mr. Wm. R. Webster disputed this rather sweeping assertion, stating that during his experience he had personally inspected several thousand tons of steel rails, using an impact apparatus which gave fairly accurate results. Mr. M. White, of the Bethlehem Iron Co., stated that his experience with impact testing machines had been anything but satisfactory, and after considerable experimenting with two such machines made by the Bethlehem Co., one in the works and the other in the laboratory, he was more than ever at sea. Such tests gave absolutely misleading results. He had found bars with little or no elongation which gave good impact results and other bars with considerable elongation which made a very poor showing under the impact test. Nowadays it was not a question of absolute breaking so much as the fatiguing of metals; a question of how long would such materials stand and not altogether how much they would stand. For these reasons the drop or impact test, which practically tested the ductility of a metal, was not in the best repute. Mr. J. A. Riehle remarked that Mr. Howard, of the Watertown Arsenal, had designed an impact machine which was being manufactured by Wm. Sellers & Co. Attention was also called to several other machines, notably one at the Watertown Arsenal, built by the government, and one built by Mr. S. Bent Russell, and described by him in the Proceedings of the American Society of Civil Engineers.

In reply to the question whether the foreign sections of the International Association were considering impact testing machines, Mr. Henning said that they were, particularly in France, where Mr. Barba was conducting a long series of experiments. Russia also used this test largely. Prof. Merriman considered the subject one of live interest about which little was known and about which more should be known. Continuing the discussion, Mr. Kreuzpointner remarked that the few breakages of car axles and wheels afforded an indication that the principle employed in the "drop test" was scientifically correct, and that such a test answered very well for commercial purposes, although it could not as yet be claimed as a reliable quantity test. Upon the motion of Mr. Henning, it was finally decided to appoint a committee of three to study this question and see what has been accomplished by foreign investigators.

As this ended that portion of the programme assigned to the afternoon session, the delegates and guests adjourned in a body to the Hotel Lafayette for dinner, so that they could convene promptly for the evening session, called for 8 o'clock.

Evening Session.

Immediately after calling the meeting to order for the evening session, Prof. Merriman announced Profs. W. H. Hatt, of Purdue University, and Edgar Marburg, of the University of Pennsylvania, as two of the committee of three on Impact Testing, the third member to be announced later. The discussion of the topic "The Relation of the International Association to Producer and Consumer" was taken up, and in the absence of Mr. Dudley, Mr. W. R. Webster presented a brief paper, in which he said:

> The International Association for Testing Materials occupies a neutral position to the producers and consumers, where the specifications, methods of testing, and methods of manufacture can be freely discussed by all parties, with the view of eventually adopting uniform specifications for each class of material.
>
> The American Section of this Association, by showing the American manufacturers and consumers that it has practical work in view, will at once secure the co-operation and assistance of both parties. We are all much interested in seeing the American export trade increased, provided our materials, bridges, locomotives, etc., are shown to be as good, or better, than those produced in any other country.
>
> At the present time the American manufacturers of steel and bridges are very much handicapped by some of the foreign specifications. In the first place, rails will not be accepted that contain more than .06% of phosphorus, and, in the second place, in many cases, basic open hearth steel will not be accepted for bridges. The railway companies are generally represented by consulting engineers, who insist that these conditions are complied with, although, in some cases, after investigation, they have accepted American practice. Are these gentlemen right to reject rails that contain over .06% phosphorus, and in refusing to use basic open hearth steel in their bridges, or, is the practice in this country right, which allows, in most cases, the use of rails containing phosphorus up to .10%, and either acid or basic open hearth steel in our bridges, provided the physical tests are satisfactory? It is right here that the American Section of this Association can be of great service, both to the manufacturer and consumer, by taking up these specifications. If the steel makers will give us freely all the information that we may ask on these matters, and our railway companies and their engineers will do the same, then we can put this information in proper shape, and bring the whole matter before the International Association.
>
> If it can be shown that the American basic open hearth steel, made from our relatively low phosphorus iron, is as reliable as the acid open hearth steel made in this or any other country, there is no reason why the International Association should not approve of its use in bridges. And, if it can also be shown that our rails made of steel containing phosphorus up to .10%, which meet all the conditions of service in this country, and in other countries where they have been used, are as reliable as any rails made in other countries, there is no reason why the International Association should not also approve of the use of rails containing phosphorus up to .10%, provided, of course, that they meet all of the physical tests called for.

Discussing the subject, Mr. White stated that the Bethlehem Iron Co. made little basic steel. There was a prejudice against this kind of steel just as there had been against Bessemer steel, and it would take time to make people believe otherwise. In this country we use better pig iron to start with, and produce better steel, which could hardly be called acid steel when refined on a basic hearth. In response to a question, Dr. Moldenke said that a good test to determine basic or acid steel was the price. However, the province of the society was to select methods of testing either material rather than to determine which was one or the other.

Mr. H. V. Wille, Engineer of Tests of the Baldwin Locomotive Works, then read a paper and presented a number of photographs to show that the extent of segregation and the number of blowholes in steel ingots was not influenced by the process of manufacture, but were governed entirely by the shape and size of the ingot and the manner in which the steel was poured.

The discussion, which had begun to wander, was brought to the original topic, and Mr. R. W. Lesley summed up the matter in a business-like manner, saying, in substance, that times are international, especially for the United States, and our expansion in connection with recent events required that we become more international. In some industries and countries old methods are maintained, not because they are best, but simply because they are old methods. This was particularly true of some of the European countries, and it was a function of the American Section of this Association to try and have specifications and rules so altered that our goods, which were better and more cheaply manufactured, could be sold unrestricted by technicalities, both at home and abroad. In addition, international testing, to be a success, must be fairly permanent, nor should the reputation of the manufacturer be ignored in making awards.

On the same subject Mr. Henning said:

> We cannot meet foreign markets unless we know foreign specifications, and it is the object of the American Section to develop and assist in the formation of a similarity of methods which would give this understanding. This should have an air of permanency to be of real value. Another of its missions was to educate foreign countries up to an understanding of what we were doing and could do. Abroad the United States was little known, and less understood, at least from the standpoint of its possibilities. And, unfortunately, this ignorance existed among engineers as well as other classes. There they are so absorbed in their own little systems and methods that they have no time for anything else, and could not realize our seemingly exaggerated statements. One of the prime objects is, therefore, to bring the producer and consumer together and convince the foreign sections of the truthfulness of our statements, the value of our methods and the quality of our products. Our manufacturers can underbid foreign manufacturers, and our goods can fill the bill, but it is necessary for our manufacturers to tell what can be done, and from the foreign members we can learn what is wanted. The same is true on this side, hence the need of a close relation between the manufacturer and the consumer, or his agent the consulting engineer. There is no danger of foreign invasion of our markets, owing to our natural advantages, our better quality of labor, and the fact that there was always a chance for advancement.

It was the opinion of a majority of those present that American manufacturers were trying to meet requirements as far as they could under existing circumstances, and that there was no doubt but that they would gladly assist the formulation of standard specifications when properly approached.

Mr. Humphrey suggested that the discussion should not be limited to steel manufactures alone, but should include all the structural branches, as was intended in the name of the Section.

As an indication of the need of standards of some sort, Mr. Kreuzpointner mentioned an incident which had come under his observation. A boiler shop which was forced to build boilers under nine different sets of specifications, while it is generally admitted that the conditions in all boilers are practicaly the same, so much so that one set of specifications would have done in this or any other shop, and the time, energy and money spent in fulfilling the other erratic specifications could be spent in perfecting the methods and materials used in the standard specifications. The trouble seemed to him to rest largely with the engineers, who, in many cases, knew considerably less about the qualities they were so carefully specifying than the manufacturers they were putting to such inconvenience.

Mr. R. W. Lesley spoke on the same topic from the cement manufacturers' standpoint. He had made a collection of specifications submitted to him to bid on, and there were 92 specifications for Portland cement and 52 for natural cements. Abroad six of the great cement manufacturing countries, turning out some 30,000,000 bbls. of cement per year, were content with six sets of specifications.

Prof. Marburg took a somewhat opposite view, and said that while standard methods of testing and standard specifications would be a good thing for the manufacturer, there was a question as to their benefit to the consumer. It was true that the multiplicity of specifications and tests now extant did put the manufacturer to expense and trouble, but it was also true that difficult specifications, if prepared by an engineer knowing his business, and not made too difficult, caused the manufacturers to improve their products. The difference in specifications was to be expected on account of the almost uncertain knowledge we have of most of our materials. From his point of view the formulation of a collection of standard specifications for all materials would not be accomplished as rapidly as some expected. However, the objects of the society were good, and there was an ample field for work.

Mr. Chas. T. Davis, Assistant Chemist, Reading R. R., mentioned an experience the Reading had had with different specifications for the material used in railway construction. Circular letters were sent to all roads in the country, having over 900 miles of track, asking for specifications of all materials used. The number of different replies received was remarkable.

Earlier in the discussion Mr. Kreuzpointner had stated that for 14 years the Pennsylvania R. R. had kept records of all boiler material, and that its present boiler specifications were based upon these data. Mr. Davis called attention to this, and stated that the Reading road had also kept similar records. The limits allowed by the two roads was appreciably different. This was mentioned merely to call attention to one of the many difficulties likely to arise in the future.

In answer to a question about time of meetings and how the proceedings would be published, it was stated that meetings would be yearly, as stated in the by-laws, unless special meetings were called by the Executive Committee. The reports undoubtedly will be published either abroad or in a special proceedings on this side. Just at present a consideration of this point was deemed premature.

◆

NATURAL GAS IN INDIANA is considered in the last report of the State Geologist, and Mr. J. C. Leach, as supervisor of natural gas, says:

> The natural gas field of the state original embraced almost 3,000 sq. miles. To-day the productive area is less than half that size. The average rock pressure was in the beginning 325 lbs., to-day it is less than 200 lbs. In the heart of the field, an area of 250 sq. miles, located in Grant, Madison, Blackford and Delaware counties, the pressure decreased 30 lbs. in 1897, and now averages but 215 lbs., while in these four counties, which are the most productive of the entire field, the average pressure is but 200 lbs. The decrease in rock pressure, added to that of an exhaustion of one-half of the original productive area and the constant encroachment of salt water toward the center of the field, all point to the final exhaustion of the supply.

◆

CHINESE SALT-WELL BORING PROCESSES, says "The Engineer," are slow but usually effective. The salt wells and petroleum wells cover an area of about 2,500 sq. miles in the Setchouen, Yunnan and Shansi districts, and about 1,200 salt wells are now worked by companies or families. These wells are from 6 to 8 ins. diameter and from 575 to nearly 1,200 ft. deep, through rock. The drilling instrument resembles a string of thick iron sausages, with a strong tempered steel point. The cable is made of thin strips of bamboo, not twisted, and is worked from the end of a strong, elastic rod, resting on a roller and with a small platform at one end. The free end of the rod is worked by four or more men like a see-saw. The drill is withdrawn from time to time and water is poured in the hole, and the muddy liquid is extracted by a bamboo piston. To prevent the walls from caving in, cylinders of cypress wood are used, connected by nails. If the cable breaks it is fished up by a variety of ingenious hooks patiently applied; and if the iron perforator breaks, it is pounded out of the way by the slow fall of heavy weights. While an ordinary well can be bored in 6 to 10 years, some wells have required 40 years of incessant toil. The salt brine is extracted by a bamboo cylinder with a valve in the bottom, hoisted by a bamboo cable rolling over a small wheel and around a huge horizontal wheel, with buffaloes as motive power.

THE THREE NEW BATTLESHIPS "Maine," "Missouri" and "Ohio," for which bids were received by the Navy Department on Sept. 1, will probably have speeds of at least 18 knots, as the modified plans of the contractors involving increased speed are likely to be accepted rather than the bids on the original Department plans, which called for a speed of only 15 to 16 knots. The bids received may be summarized as follows:

Newport News Ship-Building and Dry-Dock Co. Ship on Department plan, 15 knots speed, 11,500 tons displacement, to be completed in 31 months, $2,580,000. Ship on builder's plan, 17 knots speed, same displacement, to be completed in 32 months. $2 680,000. Ship on builder's plan, 18 knots speed, 12,500 tons displacement, 32 months' time, $2,850,000.

Wm. Cramp & Sons' Ship & Engine Building Co. Ship on Department plan, 15 knots speed, 11,500 tons, 29 months for completion, $2,650,000; or two such ships, $2,625,000 each. Ship on builder's plan, 17 knots speed, 11,500 tons displacement, 32 months' time, $2,725,000, or two such ships for $2,700,000 each. Ship on builder's plan, 18 knots speed, 12,150 tons displacement, 32 months' time, $2,885,000, or two such ships for $2,870,000 each.

The Union Iron Works. Ship on Department plan, 15 knots speed, 11,500 tons displacement, 33 months' time, $2 674,000. Ship on builder's plan, 17 knots speed, 33 months' time, $2,725,000. Ship on builder's plan, 18 knots speed, 12,200 tons displacement, 33 months' time, $2 840,000.

John H. Dialogue & Son, Camden, N. J. Ship on Department plan, 33 months' time, $2,840,000.

It will be seen from the above bids that the 18-knot vessels will be secured at a trifling increase in cost over the 15-knot vessels, which were originally designed by the Department. The increased displacement, which accompanies the increased speed, is secured by lengthening the vessels 15 to 20 ft. amidships, giving more room for engine, boiler and coal space. It is stated that the coal bunker capacity is increased to from 1,600 to 2,000 tons in the plans for 18-knot vessels offered by the bidders, while the Department plan called for only 1,200 tons bunker capacity.

The design offered by the Cramps proposes Niclausse water-tube boilers; and the Union Iron Works also proposes to use water-tube boilers. The Newport News Co., however, adhere to the use of Scotch boilers, and makes considerable changes in the battery, substituting four 12-in. guns for the four 13-in. of the Department's plan, and eight 8-in. guns for the fourteen 6-in. Ten small rapid-fire guns are also added.

◆

A CARGO STEAMER OF 13,000 TONS CAPACITY has been ordered from Messrs. Swan & Hunter, Shipbuilders, Wallsend-on-Tyne, England, by the Cunard Line, according to press dispatches from Liverpool, England. The dimensions of the vessel ordered are: Length, 560 ft.; beam, 64 ft., and depth, 42 ft., giving her a capacity of 13,000 tons of dead weight cargo, or about 20,000 tons of measurement goods. These same builders now have approaching completion for the Cunard Line the freight steamer "Altonia," of 11,000 tons capacity.

◆

THE NEW U. S. DREDGING STEAMER "Wingate Bay" had her official trial trip for speed on the Delaware River on Aug. 29. The contract requirements were for a speed of ten nautical miles per hour for four hours, under natural draft, and these requirements we are informed in a letter from the builders were fully met. The "Wingate Bay" is a self-propelling hydraulic hopper dredge, and is 140 ft. long, 30 ft. beam and 12 ft. depth. The dredging equipment consists of one 15-in. centrifugal pump which delivers into two hoppers of 250 cu. yds. capacity. The vessel complete was built for the U. S. government by the Bucyrus Co., of South Milwaukee, Wis., and the contract price delivered at Georgetown, S. C., was $73,800.

◆

THE NEW DRY-DOCK OF THE NEWPORT NEWS Shipbuilding & Dry-Dock Co. was begun on Aug. 30 with the formal turning of the first shovelful of earth in the presence of the shipyard officials and a number of visitors. The plans for this new dry-dock were prepared some months ago by Mr. Walter A. Post, General Superintendent of the company, but work was delayed on account of the war. The basin will be 800 ft. long, with a breadth of 80 ft. at the bottom and 148 ft. at the top. The depth will be 41 ft. 8 ins., from the top of the sill, giving 34¼ ft. of water at low tide. The keel blocks will extend 5 ft. above the bottom, enabling a vessel drawing 29¼ ft. of water to enter the dock. The entrance will be 106 ft. at the top and 80 ft. wide at the bottom, with granite and concrete casements. The bottom will be of stone and concrete on a row of piles bracing the entrance at each side. There will be a line of piles, six in width, down the center of the basin, on which the keel blocks will rest, while on each side of this will be a row of four piles, for the docking keel blocks to rest upon. Piles will extend from each side of the dock for a distance of 45 ft., and will be connected with the sides of the basin with crossbars for the purpose of thoroughly strengthening it. The sides of the dock will be cone-shaped concrete walls, with granite facings. At the bottom there will also be concrete with granite facing, laid upon rows of piles, with connecting cross-stringers of huge timbers in both directions. It is estimated that it will require six months to make the excavation for this immense basin, and it is hardly possible that the dock will be completed under twelve months. It will be very near and just to the north of the present dock. With two dry-docks the Newport News & Shipbuilding Dry-Dock Co. will be thoroughly equipped to handle any of the merchant or war ships afloat at any time.

◆

THE CONSTRUCTION OF TWO IRONCLADS for the Norwegian Navy is contemplated by the Norwegian Admiralty, according to reports from the British Consul at Christiana. It is stated by the same authority that the bids for construction will be called for by Oct. 8. Inquiries should be addressed to the Norwegian Admiralty, Christiana.

◆

THE IMPORTS OF CUBA AND PUERTO RICO, says the U. S. Bureau of Statistics, have averaged about $60,000,000 annually for the last decade. Of this about one-half came from Spain, about one-third from the United States and the remainder from England, Germany, France and other nations. Of this total Cuba took about 85%. The fact that Spain commanded the bulk of the traffic was due to the discriminating tariff, now abolished; and under these circumstances the class of Spanish imports is interesting. In 1895 and 1896 the chief Spanish imports, in the order of value, were: Wheat flour, shoes, flax and hemp and manufactures of these, firearms, soap, manufactures of wood, packing and cigarette paper, wax and stearin, bricks, earthenware, butter, rice and leather.

◆

BIDS FOR SMOKELESS POWDER for use on United States warships were received by the Navy Department on Sept. 3. The amount of explosive called for was 1,000,000 lbs., and the bids were made on two propositions: (1) that the government supply the alcohol and ether and (2) that the government supply the alcohol only. The bids were as follows:

	Proposition 1. Cts. per lb.	Proposition 2. Cts. per lb.
Dupont Powder Co., Wilmington, Del...	79½	80
Giant Powder Co., San Francisco, Cal...	90*	95*
Dittmar Powder Co., New York.......	80*	..
Lewis Nixon, Elizabethport, N. J........	96†	..
Laflin & Rand Powder Co..............	79½	80
California Powder Co	..	80

*For 250,000 lbs. only. †For 100,000 lbs., only.

◆

THE BALLOON IN WARFARE seems likely to have seen its best days, in view of the discouraging experience of the United States troops with the balloon at Santiago. It is evidently mere foolhardiness to send up observation balloons within range of the enemy's guns; but modern infantry rifles and light artillery can send projectiles so far that a balloon sent up out of range will be too far from the enemy's lines to discover any facts of importance, unless the weather is unusually clear.

◆

THE MOST SERIOUS RAILWAY ACCIDENT of the week was a derailment which occurred Sept. 1 on the New York, Ontario & Western R. R., at a point about four miles south of Fulton, N. Y., and which is stated to have been caused by tramps who threw open the switch at which the train was wrecked as well as two switches to the north of the wreck. The train wrecked was a fast passenger train known as the "Chicago Limited" and, it is stated, was running at a speed of 60 miles per hour when it struck the switch and was thrown over to the side track. The rapid speed made it impossible to make the sharp turn and the train left the track. The engine was thrown 20 ft. and badly wrecked; the tender was inverted, and the head coach telescoped the baggage car. A vestibuled chair car and sleeper coming behind were both derailed. The engine driver, fireman and one brakeman were killed and eleven others were injured.

◆

THE EXPLOSION OF A HARBOR DEFENSE MINE in the Mississippi River at New Orleans, La., on Sept. 3, destroyed the U. S. Government snag boat "Meigs" and killed six of the 19 men on board. The "Meigs" was engaged in removing the harbor mines at the time of the accident, and no reason is known why the explosion should have occurred.

◆

A GRADE CROSSING COLLISION between an electric car of the Troy City R. R. and the special boat train of the Delaware & Hudson Canal Co., which occurred at Cohoes, N. Y., on Sept. 5, resulted in the death of 18 persons on the electric car and the injury of nearly as many others, some of whom will probably die. The electric car contained 35 passengers at the time of the accident and was struck fairly in the center by the passenger train which was going at a high rate of speed. The responsibility for the accident has not been determined.

◆

THE COLLAPSE OF TWO 368-FT. PRATT TRUSS spans of the New York & Ottawa R. R. bridge under construction across the St. Lawrence River, near Cornwall, Ont., occurred on Sept. 6, precipitating about 60 persons into the river, of which it is estimated that fully 30 were killed. This bridge crosses the river at a point where the stream is divided into two channels by Cornwall Island. Crossing the Canadian channel a cantilever structure is being erected and crossing the American channel a three-span Pratt truss structure. Both of these structures are designed to carry a single track railway. It was the Pratt truss structure to which the accident happened. The three spans are carried by four masonry piers constructed of rock-faced ashlar masonry, with Portland cement concrete backing. The river piers rest on cribs filled with Portland cement concrete up to within 3 ft. of low water, and the shore piers rest on concrete footings placed in excavations dug 5 ft. below low water. The foundation bed consists of hard compact clay and boulders. At the time of the accident the erection of the span between piers No. 1 and No. 2, numbering from the American shore, had just been completed and the workmen were engaged in removing the traveler employed in the erection. The erection of the other two spans had been completed previously. Accounts differ as to what actually happened, one eye witness asserting that the shore span collapsed first, dragging down pier No. 2 and the next span in its fall, while others state that the foundation of pier No. 2 had become undermined by the swift current, and it collapsed, carrying with it the two spans which it supported. The latter view seems to be the one most generally accepted as correct by the contractors and others on the ground, according to the press dispatches. A strong bit of evidence in favor of the collapse of the pier first is the fact that, according to the press dispatches, not a vestige of the masonry was apparent after the accident, and it seems hardly probable that the falling of the shore span first would have caused such a total collapse of the masonry. In our next issue we hope to present in more detail the circumstances of the accident and such evidence as is available regarding its cause. The contractors for the bridge are the Phoenix Bridge Co., of Phoenixville, Pa., who sub-let the substructures to Sooysmith & Co., of New York, N. Y.

◆

THE CABLE CARS WERE STOPPED on Broadway, New York city, between the Battery and 35th St., for nearly ten hours, on Sept. 5, from a most unusual cause. The chimney of the Houston St. power station is 14 × 4 ft. in interior cross-section. It is built of red brick and lined with a thin lining, only 4½ ins. of fire brick, this lining being bonded to the red brickwork. There is a damper in the chimney, operated automatically by the steam pressure. At 2 a. m. on the morning of Sept. 5, when the damper happened to be nearly closed, a portion of the fire-brick lining fell on it and jammed it so that it could not be opened. The draft of the boilers being thus choked, the steam supply to the engines soon failed, and the cars stopped running. Several cartloads of brick and mortar were removed from the bottom of the chimney, and it was nearly noon before the cable cars were started. In the meantime horses, horsecars and drivers were secured, and for about four hours from 7.30 a. m. a horsecar service was run.

◆

AN EXPLOSION OF CELLULOID at the works of the Celluloid Mfg. Co., of Newark, N. J., on Sept. 4, and the fire caused by it, resulted in the injury of 40 persons, three of whom are pronounced fatally injured. The explosion occurred in the celluloid scrap house, and the only reason for it so far determined is the prolonged and intense heat of the past week.

WATER PURIFICATION AT WILMINGTON, DEL.

A unique system of water purification has been in use at Wilmington, Del., since the latter part of 1894. Upward filtration is employed at the rate, as designed, of 43,560,000 gallons per acre, or 1,000 gallons per sq. ft. of filter bed. The water is treated with iron before filtration, and is aerated both before and after passing the beds. The ordinary cleaning of the beds is effected by washing the filtering material while in place with both air and water. The prototype of this filter was built at Tacoma and is said to be still used at times of bad water.

Wilmington has had a public water supply since 1804. The original works were built by a company, which sold them to the borough in 1810 for $10,000, Wilmington thus being the pioneer American city in changing from private to municipal ownership of water-works. The population of the city increased from 42,478 in 1880 to 61,431 in 1890, and is now estimated at from 70,000 to 75,000.

The water supply is taken from the Brandywine Creek, being pumped from the clear water well to storage reservoirs, with repumping for a small area of high service. Although the creek has for years past received more or less organic pollution it is doubtful whether filters would have been put in as soon as they were had it not been for the large amount of suspended matter carried by the stream. The evils of pollution were officially recognized a number of years ago and steps taken to remove them, as described later in this article. It has been the practice for some time to shut down the pumps when the water is at its worst, drawing the supply from the storage reservoirs meanwhile, but these have a combined capacity of only 40,000,000 gallons, and it is, of course, desirable to keep some water in reserve. The average daily consumption for a number of years has been nearly 6,000,000 gallons, while at times the maximum consumption for several days has been much larger. Of course the maximum consumption is very unlikely to be coincident with heavy rains and turbid water, but it is not safe to count on being able to shut down the pumps for more than four days at a time.

The filter plant was designed by Mr. George H. Sellers, late Manager and Engineer of the United States Filtering & Purifying Co., Girard Building, Philadelphia, but a resident of Wilmington until his death some two years ago. Day labor was employed for the construction of the plant, which was under the supervision of Mr. Sellers and of Mr. Joseph A. Bond, Chief Engineer of the Wilmington Water-Works.

The plant consists of five filter beds, each 16 × 125 ft., and each supplemented by ducts and pipes used for aeration and the devices for adding iron to the water. Each bed is designed for a capacity of 2,000,000 gallons in 24 hours, making a total capacity of 10,000,000 gallons, with no allowances for beds out of use for cleaning. The combined area of the beds is 10,000 sq. ft., or less than one-fourth of an acre, making the rate of filtration 1,000 gallons per sq. ft. per day, or over 43,000,000 gallons an acre, with no allowance for cleaning.

A plan and sections of one of the beds are shown by Figs. 1 and 2. Water passes from the supply pipe down into a number of conical tubes, intended to suck in air with the water, and thence into a flume, where the water first comes into contact with ten bundles of revolving iron rods and afterwards has air admitted to it through the goose necks shown in the longitudinal section. After passing the length of the first flume the water returns through another one, directly below it. More air was introduced here until quite recently when the air pipes for the lower flume were taken out, on account of the difficulty experienced in keeping them open. It then divides into two parts and flows the length of the filter bed the third time, through the two side flumes shown in the cross-section. After having flowed through the 375 ft. of flumes the water passes down beneath the filter beds into the compartment entitled "sedimentation tanks." From here the water passes upward through the filter bed and out at the end it entered, after a journey of 500 ft. The filtered water for each bed passes over a copper water wheel 2 ft. in diameter and 3 ft. in length, which turns the bundles of iron rods, the power being transmitted by means of a link belt chain. Before the water goes to the pumps air is again admitted to it through a 2-in. perforated pipe, shown at the right hand end of the longitudinal section.

Scrap iron was first used instead of iron rods, about 1,600 lbs. to each bed. This was placed in square boxes and when the corners of the latter were down the increase in power required to turn them gave a jerky motion and caused the boxes to break. The rods are suspended in a chain belt. They are of common iron, about ¾ in. in diameter, and there are about 300 lbs. of iron in each bundle, or 1½ short tons in each bed. The bundles of rods make about 6 revs. per min. The attrition of the rods as they revolve on each other was designed to cause particles of iron to be deposited in the water to serve as a coagulant. The water department has no records of the amount of iron consumed in the process, but Mr. Bond states the rods have not been renewed for two years or so. Had the rods been entirely consumed in two years iron would have been used at the rate of about 0.025 grains per gallon of water. In the Anderson process of iron treatment 0.1 and 0.2 grains per gallon are taken up by the water, according to the printed matter issued by the company controlling that process.* The lower of these two rates, or 0.1 grain per gallon, would require 14.3 lbs. of iron per 1,000,000 gallons of water filtered, or 57,000 lbs. of iron for the past two years, against the 15,000 lbs. put in place two years ago, and still but little wasted. The rubbing of the rods together as they revolve seems to do little more

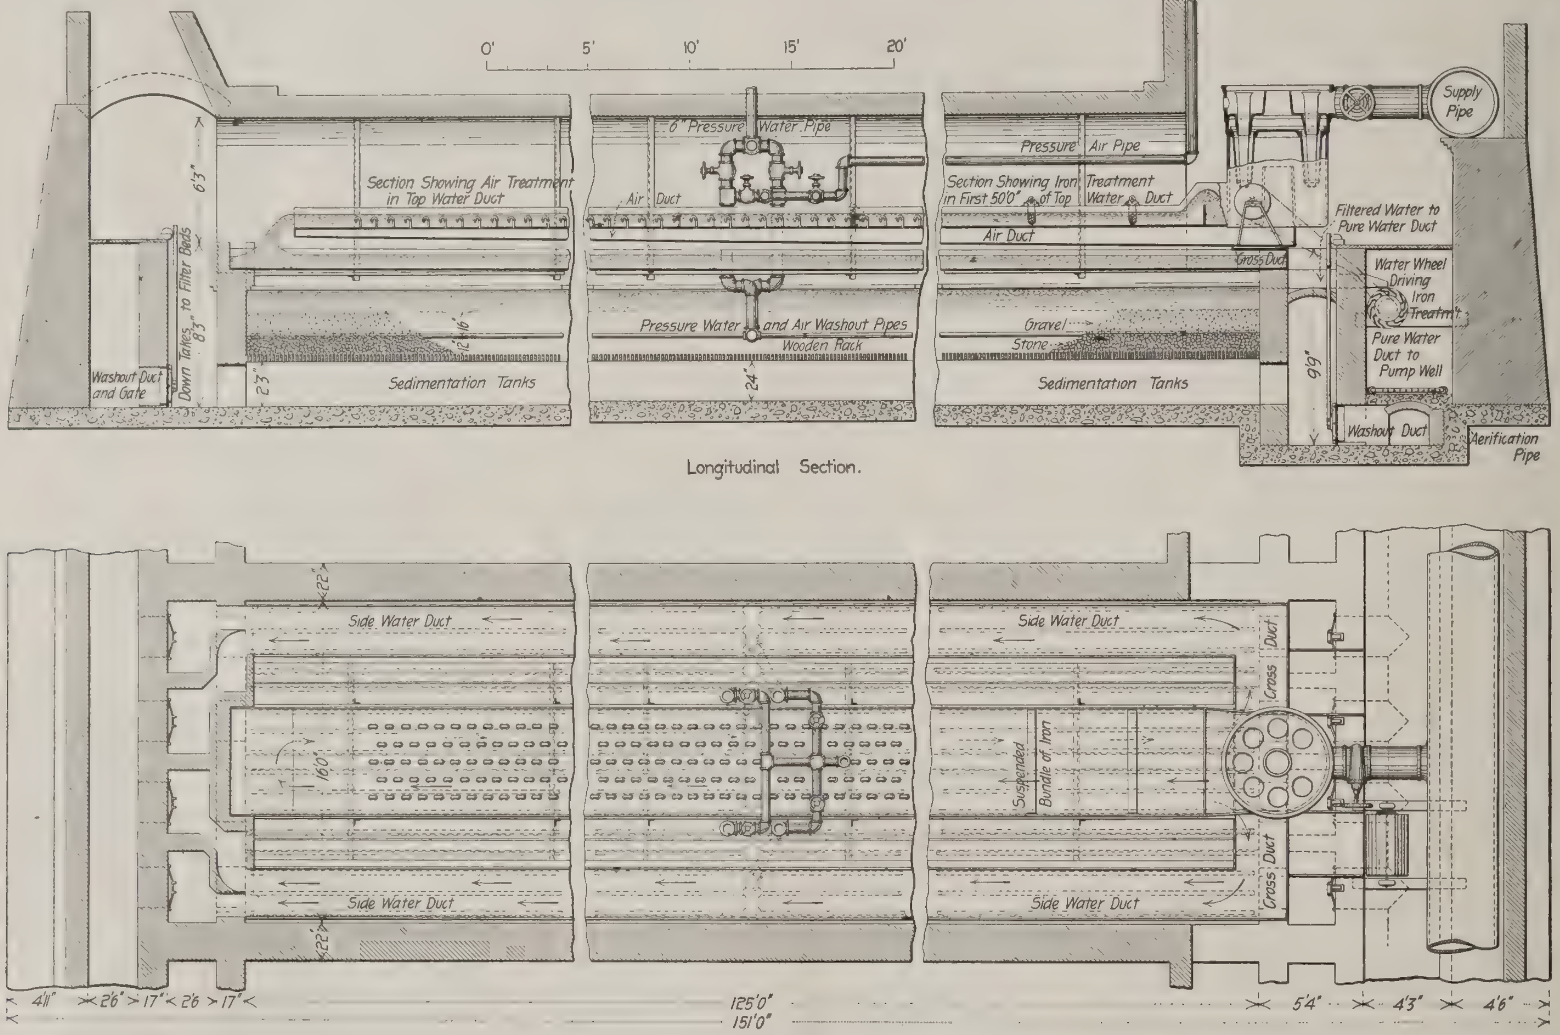

FIG. 1.—PLAN AND LONGITUDINAL SECTION OF WATER PURIFICATION PLANT AT WILMINGTON, DEL.
Geo. H. Sellers (deceased), Engineer; Joseph A. Bond, Chief Engineer Water-Works.

See p. 241, "Public Water Supplies," by Jno. W. Hill. Also see Eng. News, Feb. 14, June 6 and Sept. 5, 1885, Jan. 1, 1887, April 25, 1891 (under Society Proceedings) and Sept. 22, 1892. The Anderson process is in use in a number of places abroad.

than keep them somewhat polished, judging from the looks of the outer rods. The scrap iron, while in use, showed more wear than the rods, as would be expected.

When the plant is working at its full capacity of 10,000,000 gallons in 24 hours, or 2,000,000 gallons per bed, the time taken for the water to travel from the last bundle of rods to the sedimentation chamber is stated to be about 3½ minutes, and through the whole plant about an hour.

The air for aeration was furnished by a Clayton air compressor with an 18 × 24-in. air end until about two years ago, when a No. 4 Wilbraham-Baker blower was substituted. The blower is run by the water wheel that drives the power pumps, thus saving power, besides which the air is always available now, whereas the compressor had to stop as soon as the steam plant shut down.

The volume of air supplied is said to be about equal to the volume of water treated, doubtless meaning air at atmospheric pressure.

Originally, one whole filter bed was washed during each twelve hours, except that no washing was done for the last half of Saturday and all of Sunday. A little calculation will show that under this plan the periods between washing each bed would be alternately 2½ and 4 days. In 1896 each bed was divided into halves by plank partitions, so that only one-tenth instead of one-fifth of the plant need be thrown out of use for washing. In addition, washing is done each day now, with a "long wash" on Sunday. The filtering material was also removed and washed in 1896, one bed at a time, the "gravel and sand," to quote from the report for that year, "were again separated into their various sizes and replaced, their comparative depths (being) changed from 17 ins. of gravel and 12 ins. of sand to 12 ins. of gravel and 16 ins. of sand." This is the only time the filtering material has been taken out, washed and screened, Mr. Bond states, but reference is made further on to a clogging of the beds in 1894 or 1895, which necessitated the removal of the material.

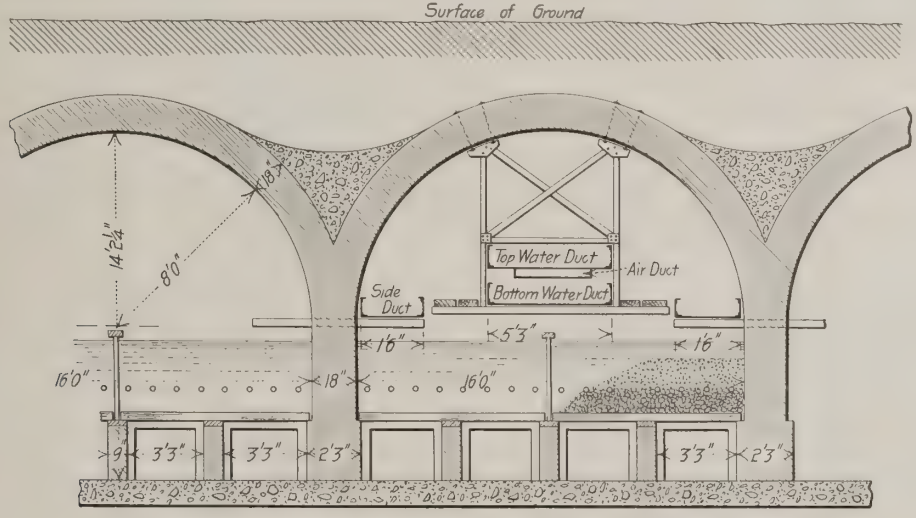

FIG. 2.—CROSS SECTION OF WATER PURIFICATION PLANT.

The original intention seems to have been to cleanse the filtering material with water admitted from above under a head of 1 ft., alternated with air admitted under pressure from beneath. In the latter case the water would still be passing upward through the bed, as when in use, but the water would be wasted. Mr. Bond stated that the air disturbed the bed by pushing the material upwards and the water carried the fine material downward. Subsequently perforated pipes were placed in the filter beds, as shown in the plan and sections. To wash the gravel the beds are now left submerged and water is wasted from below, while to wash the sand the sedimentation tanks are left filled with water and waste weirs are opened above the beds, so that the air or water, as the case may be, is forced upwards through the sand.

While filtered water has always been used for washing, as we understand it, water under pressure has been used for only about 1½ years, so that previous to this change the amount of wash water was unknown.

In 1897 the amount of filtered water used for washing was 53,183,250 gallons, or 2.6% of the total pumpage. The total amount of water pumped from the Brandywine, all of which we suppose was filtered, during the three full years the purification works have been in operation, together with the average daily pumpage, is as follows:

Year.	Pumpage, gallons. Total.	Pumpage, gallons. Daily average.
1895	2,127,600,000	5,830,000
1896	2,058,000,000	5,640,000
1897	2,041,000,000	5,600,000

There are no records of the amount of material retained by the sedimentation tanks. Every time downward washing is employed some of the sediment, if any, goes out. If necessary the sediment is further removed by the use of a stream from a hose, but this operation is not often required.

The cost of operating the filter plant is not given in the reports of the water department, but it is stated in the report for 1897 that the "expense for maintenance" for that year did not exceed "one dollar per million gallons filtered." Maintenance in the words quoted probably means all operating expenses. In the financial reports entries are made yearly under "filter account" and "filter maintenance." The former appear to include construction expenses, and the latter supplies for repairs and operation. The items under these two headings in the reports from 1893 to 1897, inclusive, are as follows:

	Filter acct.	Filter maintenance.
1893	$52,546	....
1894	38,736*	$158
1895	3,619	772
1896	4,720	425
1897	765	528
	$100,386	....

*Including $2,180 for filter house.

To the figures in the last column should be added labor, and possibly some other items, to obtain the actual cost of operation. Originally one man at $12 a week, or $624 a year, did all the work of running the filters. He now has a small amount of assistance from a laborer employed about the pumping station at $9 per week. The filter man is on duty from about 6:30 to 11:30 a. m., and from 6:30 to 11:30 p. m. No charge is made against the filter plant for the power required to supply the air for aeration nor for electric lighting. At 4% the annual interest charges on the cost of construction would be about $4,000, or about $2 per 1,000,000 gallons filtered.

Assuming the plant able to work at its rated capacity of 10,000,000 gallons per day, the cost of construction, including subsequent changes, would be about $10,000 per 1,000,000 gallons. But in the report for 1895, after the filters had been in use for less than a year, Mr. Bond recommended that their area be doubled, setting forth his reasons as follows:

> The capacity of the filter now in use, although in excess of the consumption, is insufficient to supply the pumps when they are running at their normal speed, and to decrease the speed of the pumps is poor economy, and to force the filter beyond its rated capacity is detrimental to the purity of the filtered water. If the filter area were enlarged, the rate of filtration could be lessened, and the quality of the water would be improved; besides increased facilities would be afforded for cleansing the beds, which is the secret of the efficiency of all filters. A filter of equal area to the one now in use could be built on grounds below the pumping station at a greatly decreased cost.

In explanation of this quotation Mr. Bond states that the 2,000,000-gallon water power pump is always used when any pumping is being done. This, with the 10,000,000-gallon steam pump, gives a daily pumpage of 12,000,000 gallons, which is 20% in excess of the rated capacity of the filters and 33⅓% above their capacity when a half bed is being cleaned. Under the first plan, when a whole bed was cleaned at a time, the rated capacity of the plant was reduced to 8,000,000 gallons, making the pumpage 50% in excess of the capacity of the filters. An automatic gate is provided for admitting unfiltered water to the clear water well, if necessary to supply the pumps, but Mr. Bond states that with upward filtration all the water the pumps will take can be got through the beds.

It has already been stated that the pumps are shut down when the water is very turbid, a practice followed before the filter plant was installed. This not only relieves the filters of much work, but gives them occasional resting spells. In 1894 or 1895, Mr. Bond states, it was necessary to pump very turbid water, with the result that the filtering material became so badly clogged that it had to be removed before the filters could be operated again. In view of all these facts, the filter capacity seems to be overrated when placed at 10,000,000 gallons per day and that without particular reference to the degree of purification effected. We shall not attempt to decide the proper rating, and the consequent cost of construction per 1,000,000 gallons actual capacity.

Wilmington has had a generally decreasing amount of typhoid fever, considering its growth in population, during the period for which statistics are available, or from 1881 to 1897, inclusive. The following figures show that this rate has not been notably accelerated, if at all, since the filters were started:

	Approximate population, 1 = 1,000.	Deaths from typhoid fever. Total.	Deaths from typhoid fever. Per 100,000.
1881	44	43	97
1882	46	51	111
1883	47½	32	67
1884	49	45	92
1885	51	25	49
1886	53	25	47
1887	55	37	67
1888	57	32	56
1889	59	30	50
1890	61	55	90
1891	63	35	56
1892	65	29	45
1893	67	44	65
1894	68	29	43
1895	68	27	40
1896	69	15	22
1897	70	23	33

The figures for population are of necessity only approximate. For 1881-1889 they were scaled from a population curve plotted from the U. S. census figures for several decades past. It seems to be well agreed by the city officials of Wilmington that the population of the city has remained practically stationary since 1893, and was about 70,000 in 1897. Since the latter date it is thought that it has begun to increase again, with the revival of industry.

It is to be noted that steps have been taken of late to protect the water supply from pollution. Two sanitary inspectors were appointed in 1894 to give their whole time to the sanitary patrol of that part of the stream within the state. At the start these inspectors had no authority to cause the arrest of persons polluting the Brandywine, but in 1895 this authority was secured from the legislature and is reported as being salutary, although no arrests were made that year and none are mentioned in the later reports.

Some years before the inspectors were appointed, or in 1887, the city diverted, by means of a 20-in. sewer, the waters of two small streams, Rattlesnake and Crooked runs, from the race to a point below the water-works intake. About 1887 the city began the construction of a system of intercepting sewers, which also helped to protect the water supply, although in times of heavy rain the interceptor overflows into the stream above the intake. The sewage at such times is, of course, diluted with storm water and, as has already been stated, the pumps are shut down. Since 1887, also, lateral sewers have been built with rapidity, the water mains have been extended and other sanitary improvements have been constantly in progress. Surface wells have been abandoned with the extension of the water service and those remaining in use are less liable to pollution as the sewerage system comes into more general use. Credit must also be given to improved care of typhoid patients by physicians and nurses and especially to the control of the spread of the disease through secondary infection. The milk supply, also, is doubtless less responsible than formerly for the spread of the disease.

In the practical absence of analyses of the water both before and since the filter plant was established only general impressions can be gathered from city officials and residents regarding the improvements in the physical character of the water. It seems to be agreed that the plant effects a large amount of clarification, although unable to cope with the water at its worst. Color, or stain, is only partially removed. Complaints of tastes and odors, which were heard for a few weeks some years, seem to have ceased since filtration and aeration was established, the aeration probably being the most effective agent in this connection.

We are indebted to the late Mr. Sellers for the blue prints from which the illustrations have been prepared. We are also indebted to Mr. Bond for information given and courtesies extended to a member of the editorial staff of this journal during a visit to the plant shortly after it was put in operation and again during August, 1898.

THE BELUBULA DAM, NEW SOUTH WALES.

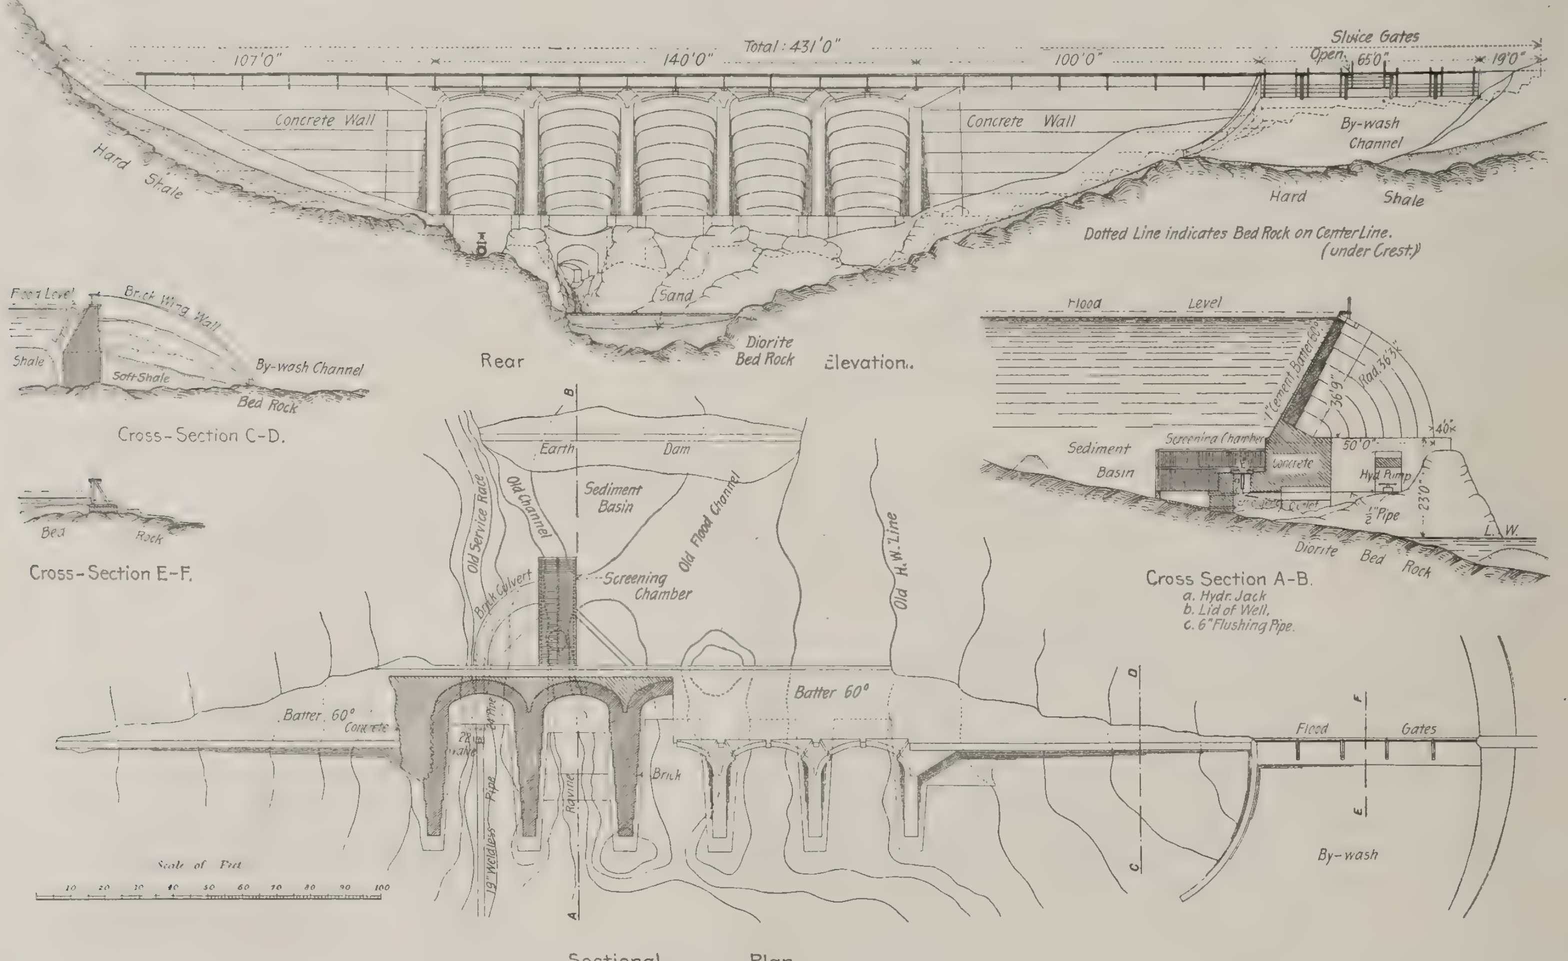
The Lyndhurst-Goldfields Co., of New South Wales, commissioned Mr. Oscar Schulze, C. E., of Sydney, to provide an installation of water power to work large deposits of low grade ore. The water was to be taken from the Belubula River, draining a watershed of 300 sq. miles, with an average annual rainfall of 30 ins. upon it. During the hot season this river is often dry for three months; and under these conditions the dam had to be of sufficient size to impound the water necessary to run three turbines, aggregating 200 HP., for these three months. As described in "Indian Engineering" (from which journal we have also reproduced the accompanying cuts), Mr. Schulze located the dam at a point on the river just above a succession of falls, with a total descent of about 175 ft. At this point the river had cut out a narrow gorge in diorite rock. The valley above this gorge is of such width and slope that a 16-ft. depth of water stores about 87,120,000 cu. ft., and gives a head of nearly 200 ft. on the turbines located about one-half mile below the dam.

The design of the dam is most unusual. The rock at the bottom of the site was found to lie in a number of sharp ridges parallel to the axis of the stream, with deep channels between. A buttressed face-wall was therefore determined upon. The locality afforded facilities for brickmaking, and this brick was found to be the cheapest material and the one with which the dam could be most quickly built. Owing to the deep hollows between the ridges of the bed of the stream, an ordinary double-faced wall would have been difficult to construct without expensive foundation work.

The total length of the dam, including overflow, is 431 ft. on the crest; the greatest height is 60 ft., with a concrete foundation varying from 1 to 23 ft. in height and above that 36 ft. 9 ins. of brick work. There are six buttresses, 28 ft. apart c. to c., and each 40 ft. long, and 12 ft. wide where they abut against the wall and 5 ft. wide at the outer end. Each buttress, as carried up in brick work, forms a segment of a circle with a radius of 36 ft. 2 ins., and it decreases in thickness from 8 ft. 6 ins. at the center to 4 ft. on the outer circumference. These buttresses form piers for five elliptical, brick arches, which are 4 ft. thick at the bottom, 1 ft. 7 ins. at the top, and lean forward on an angle of 60°. The spandrels between the arches were filled with concrete, and this concrete covered the crown of the arches to a depth of 12 ins. and joined the side walls of the dam, which were also made of concrete, with large boulders imbedded to save expense. These side walls were built on the same angle of 60° on the water-face, but were vertical on the other, with a top width of 2 ft.

The overflow, built at one end of a side wall, is 65 ft. wide, and is divided into five sluiceways; provision is also made for the water to run over the dam between the buttresses in extreme high water. The arched outlet in the base of the dam, which was left open during construction, is fitted as an emergency outlet by building out a projection on the water-face of the dam with a 5 ft. well in it covered with a 12-in. wooden lid that can be raised by a 50-ton hydraulic ram, worked by a pump at the back of the wall. The 12-in. service outlet pipe is carried through the wall with an entrance made of a tapering and rising brick culvert. The entrances to this culvert and to the two 6-in. flushing pipes are covered by a grating and surrounded by a sediment basin, formed by building an earth dam across the river bed. This same dam diverted the water to the temporary outlet during construction.

The dam contained about 6,000 cu. yds. of concrete and 500,000 bricks, and the total cost of the dam was less than $45,000. To prevent gradual silting up, a cribwork will be built later across the upper end of the valley.



BRICK AND CONCRETE DAM WITH BUTTRESSES ON THE BELUBULA RIVER, NEW SOUTH WALES, FOR THE LYNDHURST GOLDFIELDS CO.
Oscar Schulze, Sidney, Australia, Chief Engineer.

LOSSES FROM IRRIGATION AND OTHER CANALS BY SEEPAGE.

In our issue of June 23, 1898, we published an article on "The Loss of Water from Reservoirs by Seepage and Evaporation," in which we gave the conclusions of Prof. L. G. Carpenter on this subject, as set forth by him in Bulletin No. 45 of the Agricultural Experiment Station, Fort Collins, Col. The same institution has now issued Bulletin No. 48, also by Professor Carpenter, on "Losses from Canals from Filtration or Seepage." This bulletin is based on measurements made under Professor Carpenter's direction, on years of general observation, and on measurements made by others in this and foreign countries. The bulletin may be obtained by applying to Professor Carpenter, or the director of the station. Its conclusions are as follows:

> (1) The losses from evaporation are relatively insignificant compared with the seepage losses from most canals. In the cases most favorable to evaporation and least favorable to seepage the evaporation is not over 15% of the seepage.
>
> (2) In the case of reservoirs it was concluded in Bulletin 45 that the seepage was less important than the evaporation. This is different from the results found in ditches, not because the evaporation is less, but because the seepage is much more.
>
> (3) The losses are sometimes enough to cover the whole canal 20 ft. deep per day.

(4) The loss in clay soils is less than in sandy or gravelly soils, but rarely as small as 3 ins. daily.

(5) The loss is greater when water is first turned in than after the bed has become saturated.

(6) Sometimes the canals are found to gain for the whole or part of their length, or the canals may act as drains. This is more likely to be the case when the canal is deep in the ground, when crossing lines of drainage, or when located below other ditches or irrigated tracts.

(7) In the prevailing Colorado soil, when not intercepting seepage, the loss may be put provisionally at from 1 to 2 ft. per day over the whole surface of the canal. In clay soils it is less, but still nearly one-half as much.

(8) The loss in carrying water in small quantities is relatively larger than in carrying large amounts. The increased depth of water means increased leakage. but the carrying capacity increases faster than the leakage.

(8a) From the standpoint of economy it is wasteful to run a small head. It is more economical to run a large head for a short time. In the management of small ditches the time system of distribution can be introduced to advantage, saving time and labor as well as water.

(9) It is wasteful to use two ditches or laterals when one would serve.

(10) The loss increases with higher temperature, being about twice as much at 80° as at 32° F.

(11) The loss increases with greater depth of water, but the exact relation needs further investigation.

(12) The loss will be lessened by any process which forms or tends to form an impervious lining or coating of fine material, as of clay or silt. The silt, consisting of fine sand, improves many soils. Clay is better, and especially limy clay, the lime with the clay forming an almost impervious coating.

(13) Cement linings as used in California and Mexico are not warranted by the conditions in Colorado, nor would the weather conditions be favorable. Nor is the use of wooden stave piping for this purpose likely to be profitable in many places in the state, if at all on the larger canals at present. The silting process applied with discrimination will accomplish much at smaller cost.

(14) On small laterals glazed sewer pipes may save annoyance often connected with the carrying of water in laterals for considerable distances, which, with the saving of water, may make its use an object. One of the supply laterals of the Colorado Agricultural College is of vitrified sewer pipe, over 4,000 ft. of 12-in. pipe being used.

(15) Some particular sections in canals are subject to much greater loss than the canal as a whole. Hence water can be saved by locating the leaky place and remedying it. This may be desirable to do while it would be unprofitable to treat the whole canal.

(16) There are many places where it would be advantageous to combine two ditches, by this means saving not only the loss of water, but saving superintendence and maintenance charges. With increased confidence in the accuracy of water measurement, reluctance to such consolidations should lessen.

(17) The depth of losses from laterals is probably greater than in the main ditches. The laterals are less permanent, are steeper, have less silt, and are more poorly cared for.

(18) There must be some arrangement of ditches and laterals which is the most economical for given conditions, so that the aggregate of the losses of the whole system will be a minimum. Certainly the location and arrangement of the laterals for carrying water from the main ditch is worthy of consideration by the management of the main canal, and the importance increases with the size of the canal and the width of the strip it serves.

(19) It is not to be understood that the whole of the loss from the ditches is lost to the public wealth of the state. Some, perhaps much, of the loss, may reappear as seepage in lower ditches or in the main stream and again be used. It is, however, lost to the particular ditch and incidentally is destructive to much land. With all practicable methods of prevention, there will still be abundant loss. It should be to the advantage of the individual ditch to prevent such loss as far as practicable.

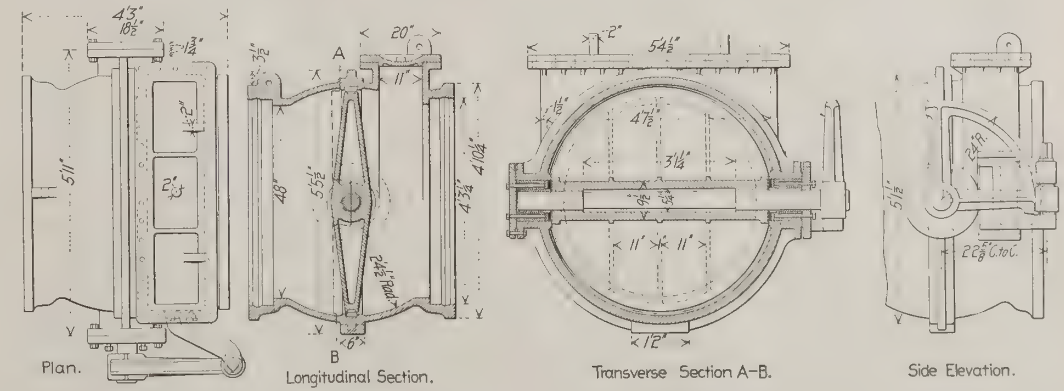
(20) A general statement of the total amount of loss of water must be made and accepted with reservation. It would appear that in the main canals from 15% to 40% is lost, and in the laterals as much more. It would thus appear that not much over one-half, certainly not over two-thirds of the water taken from the stream, reaches the fields. In the most favorable aspect, the loss is great, and is relatively greatest when the loss can be least afforded, viz., when the water is low and the ditches are running with reduced heads.

(21) There are some 2,000,000 acres of land irrigated in Colorado, and the value of the water rights, at a low estimate, is as much as $30,000,000. (The census estimates the water rights as worth $28.46 per acre.) On this basis, the capital value of the water lost by seepage in the canals and ditches may be put at from $6,000,000 to $10,000,000. From the evidence at hand at present this seems a low estimate.

◆

A 48-IN. ROTARY VALVE.

The accompanying cut shows the details of a 48-in. rotary valve, made by the Viney Independent Gate Valve Co., Ltd., Lippincott Building, Philadelphia. The two principal advantages of this valve are the quickness with which it can be opened or closed and the small space which it requires. The manufacturers claim that two men can open one of these valves in one-tenth the time required to open an ordinary lift valve. The body of the valve has a diameter only 8 ins. in excess of that of the pipe on which it is placed. This feature is valuable where valves are placed in any limited space, especially beneath street surfaces. In the city of Philadelphia about 150 of these valves, from 20 to 48 ins. in diameter, are placed beneath the streets.



A 48-IN. ROTARY VALVE MADE BY THE VINEY INDEPENDENT GATE VALVE CO., PHILADELPHIA, PA.

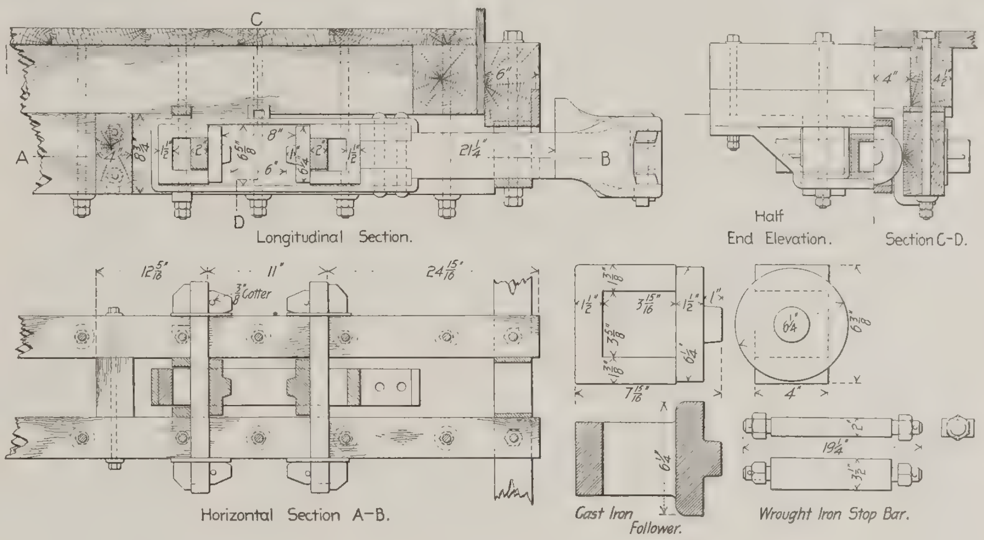
NEW FREIGHT CAR DRAFT RIGGING OF THE PENNSYLVANIA R. R.

About a year ago the Pennsylvania R. R. and allied lines secured the license to use a new draft rigging for freight cars, which promises to reduce materially the cost of maintenance of this class of equipment, draft rigging repairs being generally conceded to be one of the largest items of expense in car repairs. This new device was first tried on a number of cars on the South West System, which ran for a year without showing any signs of weakness in the parts belonging to the draft rigging, after which the Pennsylvania R. R. proper also equipped a number of its cars with the same device. As many of these cars as could be reached were recently examined, and after 1½ years' service their draft riggings were found to be in perfect condition, not a single part needing renewal in the whole lot. As far as known by the officials, not any of these cars have had any repairs done to their draft rigging since they were turned out, nor have any draft springs been found broken on them.



IMPROVED FREIGHT CAR DRAFT RIGGING; PENNSYLVANIA LINES.

Some of the cars have been exposed to unusually rough handling and have been in collisions, yet it is stated that although the couplers or the cars themselves have been more or less injured, the draft riggings have so far escaped all damage. In one instance, it is stated, a yard engine backed down into a cut of cars, of which the first one had this draft rigging, with such a force that the car, which was a flat car, had all its sills broken in two and the body doubled up like a jack-knife, yet, when the wreck was cleared off the draft riggings at both ends were found intact, draft sills and all, and the complete outfit was applied to another car the next day, without repairing any parts, except straightening some of the bolts securing the draft sills to the center sills.

In another instance a train parted between the engine and the first car, on account of a broken knuckle. The cars bumped up against the tender with such force that the tank shifted 1 ft. on the frame, and the end sills on the first car, which had this draft rigging, broke, but the rigging itself was not damaged. The following two cars, which had a different kind of draft rigging, had it broken, on one car at both ends.

An interesting test was also made at Columbus, O., about a year ago, when two cars with these draft riggings were each coupled to a locomotive headed in opposite directions. The cars were connected by means of a 30-ft. switch rope looped around the knuckle. The engines were then started at full speed, and when the rope tightened up it produced a jerk sufficient to snap off one knuckle by shearing off the pin, cracking another knuckle and bending two other knuckle pins. There was no damage done to the draft rigging of either car.

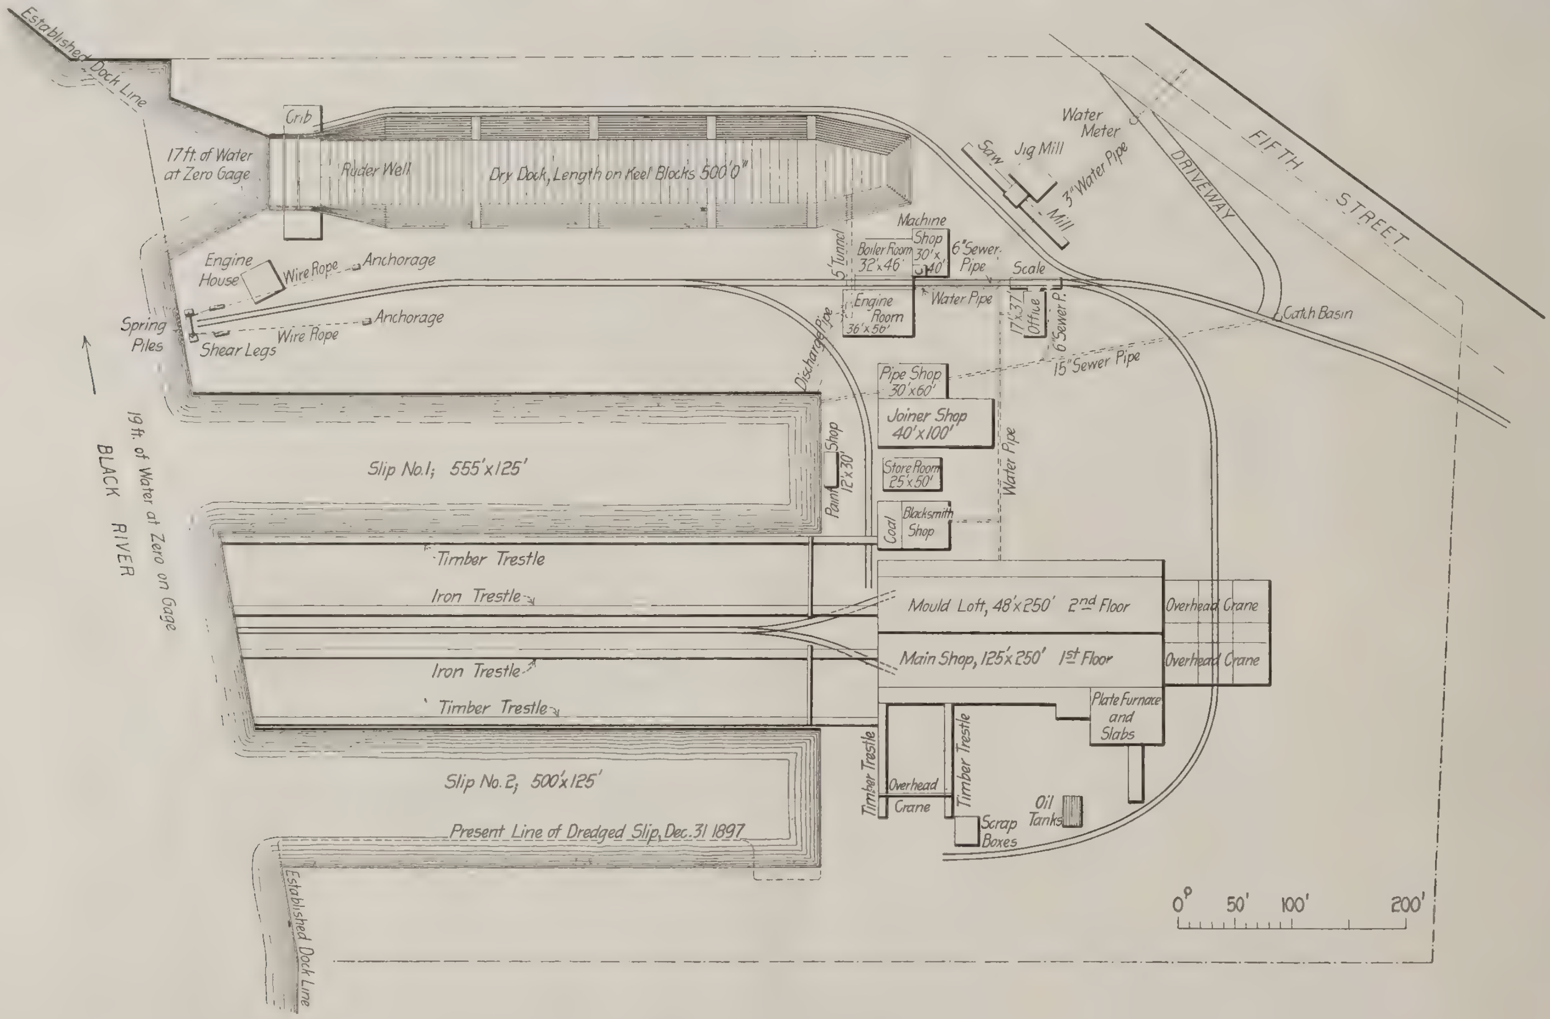
The strength, which this form of draft rigging possesses, is not, however, its principal advantage, which is the ease with which it can be taken down and put up, and the short time required to renew a coupler, the latter job having frequently been done in six minutes, often without switching the cars out of the train. To do this work it is only necessary to remove the nuts or keys securing the stop bars on one side, and then drive these stop bars through by means of a long stick projecting beyond the side of the car, where there is plenty of room for using a sledge. If a draft spring should need removal, which has not happened yet, however, the back end of the coupler with the tail strap is tipped down on the carrier iron, after the stop bars have been removed.

In the accompanying illustration two different kinds of fastenings for the stop bars are shown, which are both being tried. The one with keys instead of nuts reduces the machine work, and makes it possible to renew all parts of the draft rigging at any blacksmith shop without special tools or formers, which may be a decided advantage for cars that are apt to get out of order at distant points, away from regular repair shops.

It is estimated that this form of draft rigging can be made and applied cheaper than the one in the M. C. B. recommended practice, and it is claimed to have a decided advantage also in that it may be applied to draft sills spaced as close as 5 ins. Another feature is that the spring cannot be compressed solid, which is probably the reason why, so far, no springs have broken. It is understood that the device is to be tried on some new steel cars of large capacity, for which it is considered well adapted on account of its strength.

THE LORAIN SHIPYARD OF THE CLEVELAND SHIP BUILDING CO.

The Cleveland Ship Building Co. has recently completed a shipyard and dry dock, at Lorain, O., 26 miles west of Cleveland, and the entire plant is now in operation. The designs were prepared by Mr. James Ritchie, M. Am. Soc. C. E., of Cleveland, who also superintended the construction. The accompanying drawings show the general arrangement and details of the work. The dry dock has a total length of 560 ft., a width on top of 96 ft. between copings, a width on the bottom of 59 ft., and it will hold a vessel of 500 ft. length on the keel. It is built of timber and piling and has a steel gate, giving an entrance 60 ft. wide on the bottom and 66 ft. on the top, with a depth of 17 ft. of water on the sill at the ordinary stage. The entrance is protected by two timber cribs, and the aprons are of timber on piling. The spaces between the piles are filled with concrete, and the cribs are filled with puddled clay.



GENERAL PLAN OF THE SHIPYARD AND DRY DOCK OF THE CLEVELAND SHIP BUILDING CO., AT LORAIN, O.

James Ritchie, Chief Engineer.

The bottom and slopes of the dock are constructed of piles capped with longitudinal 12 × 12-in. oak timbers. The transverse timbers of the bottom are 12 × 18-in. Douglas fir. There are 63 of these timbers, 50 of them being 64 ft. in length, and the others varying in length from 64 to 32 ft. The slope timbers are 12 × 12-in. and 8 × 12-in. alternately, and 32 ft. long, framed into the transverse floor timbers. The slope timbers are covered by 1-in. pine boards, and upon these are laid the alters or steps. The floor consists of 4-in. pine planks laid on the longitudinal timbers, between the long transverse timbers. There are two drains, one at the foot of each slope, and they unite at the east end of the dock in a cross drain, leading to a brick tunnel, 5 ft. in diameter, which conveys the water to the pumps. The latter are two in number, each having a 30-in. discharge, and together having a pumping capacity of 50,000 gallons per minute. They were built by the Southwark Co., of Philadelphia, and have performed their service with entire success.

The dock is enclosed by a line of 6 × 12-in. tongued and grooved sheet piling, driven 20 ft. into the ground, and anchored to round piles outside by 1¾-in. iron rods. The rudder well is 10 × 15 ft., and 10 ft. deep, with a concrete bottom 24 ins. thick, the sides being protected by sheet-piling. The work of construction was commenced on Feb. 22, 1897, and the first boat docked was the "Sir Wm. Fairbairn," 438 ft. long, on Jan. 26, 1898. Since that date there have been six other large steamers docked with uniform success.

The power-house and main shop are shown on the plans. The shop is equipped with overhead traveling cranes, with all necessary tools for handling and shaping the plates and shapes for the building of ships. Each tool has a pneumatic hoist for handling the material, and all the tools are operated by electricity generated in the power-house, each tool having an independent motor. There are at present two berths for building ships, and over each is a traveling crane operated by electricity, and supported by the timber and iron trestles shown on the general plan between Slips Nos. 1 and 2. The iron trestle is fixed in place, while the timber trestle is movable, and will be taken down when the vessel is ready for launching, as all vessels are launched sideways on the lakes. There will be space for building four vessels at one time in this yard, but only two are now being built.

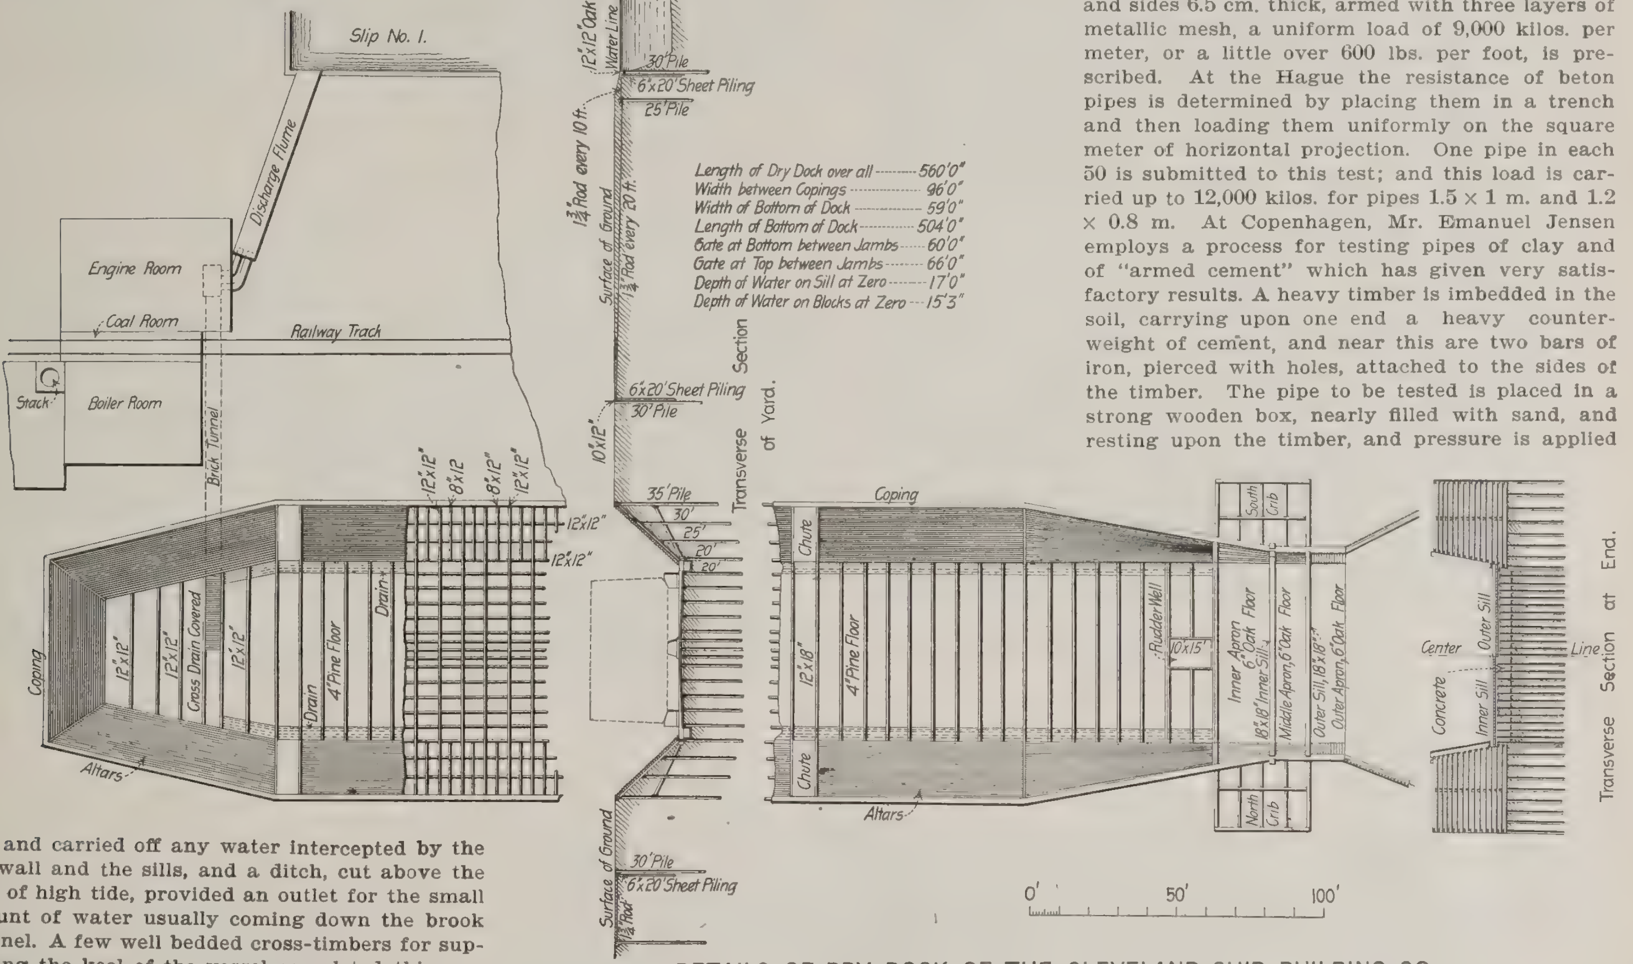
The sides and ends of the slips and the river front are protected by piling and sheet-piling, anchored back to other piles, by 1¾-in. iron rods. Under each berth are six rows of piles, capped with 12 × 12-in. oak timbers, for supporting the ships during construction. The railroad tracks shown on plan serve to transfer the material from the main line to the various overhead cranes shown on the plan, and everything has been designed with a view of simplifying the handling of material.

The framework of the main shop is of steel construction, with the first floor divided into two rooms, each 40 ft. wide by 250 ft. long, with a passageway between them 15 ft. wide, in each case measured from centers of columns. The clear headroom in this first floor is 18 ft. 6 ins.; and each 40-ft. space is covered by a traveling crane, running upon tracks on the four sets of side posts. The mold-loft is located over one-half of this first floor; it is 48 ft. 9 ins. wide, from out to out of side posts, 8 ft. 6 ins. high in the clear, and is covered by a flat, trussed, timber roof, with a 4-ply tar and gravel roof. The other half of the main floor is also covered by a tar and gravel roof laid on ⅞-in. matched pine boards, resting upon the main plate girders. Outside of the lower floor of the main shop are two parallel wooden sheds, each about 15 ft. wide, with one of these sheds terminating in the plate furnace, as shown on the general plan. The heating furnaces, for preparing plates and shapes for bending, are operated by crude oil fuel.

A NATURAL DRY DOCK.

We are indebted to Mr. T. Hodgson, of Bedford, Province of Quebec, for a description of a natural dry dock and the manner in which it has been utilized. This dock is on the Maine side of the St. Croix River, between Calais and Passamaquoddy Bay. At this point a small brook has cut a channel of sufficient width through the river bank down to about the level of low tide; the difference in tide levels at this place being nearly 25 ft.

As there was a considerable amount of shipping owned in this neighborhood and docking facilities were absent, some ingenious Yankee concluded that he would utilize the cut made by the small stream; especially as the high range of tide provided all the appliances needed to fill and empty the dry dock. Starting several hundred feet from the river, on the small tributary, a cut was made across the bed of the stream, extending into each bank, and a ten-foot wall of stone laid in cement was built. At the center opening the top of this wall was about on the level of the bed of the stream; but at the sides it extended above the highest tides. Sills were laid in the opening and a pair of ordinary lock-gates were put in place, opening outwards. A pipe controlled by a valve was laid in the center wall level with the stream bed, and carried off any water intercepted by the low wall and the sills, and a ditch, cut above the level of high tide, provided an outlet for the small amount of water usually coming down the brook channel. A few well bedded cross-timbers for supporting the keel of the vessel completed this serviceable dry dock.



Length of Dry Dock over all ---- 560'0"
Width between Copings ---- 96'0"
Width of Bottom of Dock ---- 59'0"
Length of Bottom of Dock ---- 504'0"
Gate at Bottom between Jambs ---- 60'0"
Gate at Top between Jambs ---- 66'0"
Depth of Water on Sill at Zero ---- 17'0"
Depth of Water on Blocks at Zero ---- 15'3"

DETAILS OF DRY DOCK OF THE CLEVELAND SHIP BUILDING CO.

The operation of the dock was very simple. The vessel came up the river on the flood tide and was hauled into the dock and held in position over the keel blocks as the tide ran out. As the water level lowered shores from the banks kept the vessel upright, and these are found sufficient for the class of vessel using this dock. When the tide had ran out the gates were shut and the water was kept out until repairs were completed. To undock the ship the gates can be opened at low tide and the water thus admitted on the rise of tide will float the vessel, and she can pass out and down stream on the ebb tide. This dock has been in successful operation for some years, and is an interesting example of the utilization of existing natural conditions for securing a much-needed convenience.

EUROPEAN METHODS OF TESTING SEWER PIPES OF CEMENT AND CLAY.

The International Association for the Testing of Materials, in 1896, appointed a committee to investigate the methods of testing sewer-pipes of cement and clay, as up to that time there had been no uniform method of testing, and practice varied widely. Mr. Gary, chief of the section for the tests of materials, at the test laboratory at Charlottenburg, was directed to take charge of this investigation, and his preliminary report is published in "Les Materiaux de Construction," Nos. 23, 24, the official organ of the Association.

Mr. Gary, in 1895, had already investigated, for the German Association of Manufacturers of Portland Cement, the methods employed by governments, municipalities and individuals in testing the strength of cement pipes. He found that these tests varied in each case, and none were regarded as complete for the purpose intended. Similar conditions existed in other countries than Germany.

In the investigation to be made Mr. Gary concluded that the points to be determined were as follows: The resistance to internal and external pressure; impermeability; resistance to the attack of acids; and the wear upon the interior by sand passing with the water. The tests should then mainly determine the bursting and crushing strength, and the texture and composition of the paste used. The resistance to exterior pressure is the most important property in a cement or clay pipe; for, with a few exceptions, such pipes are simply covered with earth or sand, and are not placed in masonry. The pressure upon them will differ as these pipes are laid under traveled streets, under railway embankments, or under the foundation walls of buildings; and it is necessary, in passing judgment upon the fitness of these pipes, to distinguish between the loads to which they are to be subjected in use. Mr. Gary then details the practice of a number of German cities in the test of cement pipe, as follows:

The Department of Public Works of Liegnitz requires that a cement pipe one meter (3.28 ft.) diameter should resist the pressure of a layer of earth 3 meters (9.84 ft.) thick; at Rosenheim, pipes covered with 12 to 16 ins. of earth should resist the pressure of a heavy vehicle; and at Colmar, when there is any doubt of the solidity of a pipe, a loaded wagon is passed over the laid pipe. At Schwerin, in Mecklenburg, cement pipes must resist, without cracking, a pressure equal to 50 kilograms per linear meter and per centimeter of diameter. This test is made by placing railway rails on the top of the uncovered pipe. The city of Freysing prescribes that the pipe should support a "load of 6,000 kilos, concentrated upon the top of the pipe"; and Passau demands that the pipe resist a pressure of 805 lbs. per lin. ft. At Zeitz, where the pipes are buried 6 to 8 ft. beneath the surface, a steam road roller is passed over them before acceptance. Clay pipes, 1 meter diameter, have been tested at Mannheim, by burying them in the earth, with a covering layer about 18 ins. thick. Over the pipe was then placed a double plank platform, about 3 ins. thick in all, and 3.28 ft. square, and on this was placed the test load. The rupturing load was found to be about 28,600 lbs.

For the test of pipes of "armed-cement," or cement reinforced by a double iron mesh on the Zisseler system, the engineer of bridges, at Breme, prescribes the following test: The pipe is buried in sand in a solid wooden box; then by means of a cover fitting inside the box a pressure of 7,500 kilos. per running meter, or about 500 lbs. per lin. ft., is applied to the pipe. The pipe is required to stand this pressure without deformation or cracking. For pipes of oval section, 120 × 96 cm., and sides 6.5 cm. thick, armed with three layers of metallic mesh, a uniform load of 9,000 kilos. per meter, or a little over 600 lbs. per foot, is prescribed. At the Hague the resistance of beton pipes is determined by placing them in a trench and then loading them uniformly on the square meter of horizontal projection. One pipe in each 50 is submitted to this test; and this load is carried up to 12,000 kilos. for pipes 1.5 × 1 m. and 1.2 × 0.8 m. At Copenhagen, Mr. Emanuel Jensen employs a process for testing pipes of clay and of "armed cement" which has given very satisfactory results. A heavy timber is imbedded in the soil, carrying upon one end a heavy counterweight of cement, and near this are two bars of iron, pierced with holes, attached to the sides of the timber. The pipe to be tested is placed in a strong wooden box, nearly filled with sand, and resting upon the timber, and pressure is applied to it by a lever and saddle with the lever support on a pin passing through the holes in the iron bars. The advantage of this process is that the commencement of cracking in the pipe can be noted; though this is of little advantage in the test of clay pipes, as after the appearance of the first crack the pipe will support but little more. But in the case of the Monier and Zissleer construction, where the iron skeleton augments the cohesion of the material, the appearance of the first fissure precedes by some time the final crushing load.

At the test laboratory at Malines, the resistance of pipes to exterior pressure is tested by a Kirkaldy machine; the pipe being placed between two wooden saddles which each embrace one-third of the circumference of the pipe. But as it is difficult to insure contact with all the inequalities of the pipe, the process is not satisfactory.

From the report of Mr. Gary it seems that about the only sewer pipe tests so far employed relate to the resistance against exterior pressure; and he well remarks that a uniform, systematic and reasonable test of sewer pipe, of various materials, has yet to be devised; or, at least, to be introduced, into general practice.

A STEEL CROSS, 88 ft. high and 60 ft. wide, designed to carry electric lights and other decorations will be built and mounted on the Court House tower during the convention of Knights Templar, at Pittsburg, Pa., in October. The trunk and arms of the cross are made of 5 × 3 × ⅜-in. angles, in the form of a lattice column and girder, which is 12 ft. in width.

SUBSCRIPTION RATES: United States, Canada and Mexico, One Year, $5.00; *6 months,* $2 50; *2 months,* $1.00. *To all other countries in the Postal Union: Regular Edition, One Year,* $7 60 *(31 shillings); Thin Paper Edition, One Year,* $6.31 *(26 shillings). SINGLE COPIES of any number in current year,* 15 *cents.*

Mailing addresses may be changed at will by sending both old and new address. The number on the address label of each paper indicates when subscription expires, the last figure indicating the year and the one or two preceding figures the week of that year; for instance, the number 328 *means that subscription is paid to the 32d week (that is the issue of Aug.* 11) *of the year* 1898; *the change of these figures is the only receipt sent, unless by special request.*

ADVERTISING RATES: 20 *cents per line. Want notices, special rates, see page* 18. *Rates for standing advertisements sent on request. Changes in standing advertisements must be received by Monday afternoon; new advertisements, Tuesday afternoon; transient advertisements by Wednesday noon.*

We deem it in no way inappropriate to make some reference in these columns to what may well become one of the most notable events of modern times, the formal announcement by the Czar of Russia of an International Conference looking to the disarmament of the great nations of the world, to the extent at least to which their standing armies and navies are a menace to each other. No words of ours can add emphasis to the language with which this absolute ruler of a hundred and thirty millions of people portrays the horrors of war, and the crushing burdens which Europe's vast military armaments impose upon her people. As His Majesty truly says:

> To put an end to these incessant armaments and to seek the means of warding off the calamities which are threatening the whole world—such is the supreme duty imposed to-day upon all states.

The people of this nation, as a whole, will welcome with heartiness this word for peace, spoken by the man who more than any other one man living holds the destinies of nations in his hands. The United States maintains its army and its navy as a means of national defense, and by its fortunate location and its own varied natural resources, it is more secure against foreign invasion and attack than any other nation of the earth. Certainly, this country will never seek to make its military strength a menace to the welfare of any other civilized nation, and its good will toward other members of the great family of nations is such that it should gladly co-operate in every endeavor to increase international comity and reduce the burdens under which European nations now suffer.

The riots at Milan last summer are an indication of conditions in Southern Europe which cannot be overlooked. If civilization is to be maintained, and if governments are not to be swept downward by a wave of anarchy, the crushing burdens under which the people are struggling must be lightened. The vast waste of life and energy and treasure in military and naval armaments must be stopped. Of course, sufficient military forces to preserve internal order and to maintain the governments which civilized nations have established in barbarous lands are a necessity; but the frantic struggle to show superiority over one's neighbor in size of armies or strength of fleets has reached a stage where its burdens are only to be compared to a state of permanent warfare.

The United States, in the full flush of rejoicing over its unparallelled victories in the war just closed, does not forget that its war was fought to bring peace to lands where war, and oppression only less onerous than war, had been the rule for a century. We want no wars, and especially no wars of conquest or aggression; and it is to be sincerely hoped that our government may cordially welcome and do all in its power to further the great reform which the Russian Emperor has set on foot.

◆

The agitation for higher speed in the three new battleships, "Maine," "Missouri" and "Ohio," which was begun in the editorial columns of this journal last June and was continued in the newspaper press throughout the country, receives ample vindication in the bids for the new vessels which were opened at the navy department Sept. 1 and are published on the first page of this issue. It appears from these bids that American shipbuilders are ready to build battleships with a guaranteed speed of 18 knots at a trifling increase in cost over vessels of 1,000 tons less displacement and 3 knots slower speed. No small credit is due to Secretary Long for his fairness and open-mindedness in hearing the arguments in favor of higher speed, and deciding upon the issue of the supplementary circular to bidders, under the terms of which the plans and proposals for 18-knot vessels have just been submitted. That these proposals will be accepted seems hardly open to question, unless, indeed, the naval authorities should decide to reject all these bids and call for new bids for the 13,500-ton battleships which are contemplated in the comprehensive naval program that has recently been framed. In view of the limit of cost, $3,000,000, set by Congress, however, it seems most likely that the present plans for 18-knot vessels will be accepted.

◆

The Engineers' Club of New York city paid a well-deserved compliment to the engineers who have been on active duty with the fleet off Santiago, when it tendered them a dinner on Thursday evening, Sept. 1, at the club's house. It is frequently deplored that in the report of our naval engagements, and in the public mind, small credit is given to the heroes who fight below decks in temperatures that are oftentimes more of a menace to life than the shots from an enemy. It is entirely proper that organizations of engineers should take the lead in remedying this and in according public honors and distinctions to the men whose heroism and devotion to duty are often as great as those of any officers on the vessel, and who contributed in no small degree to the glorious victory won on July 3.

◆

As one of the results of the annexation of the Hawaiian Islands and of the possible large expansion of United States territory, in Cuba, Porto Rico and the Philippines, frequent enquiries are already reaching this office regarding the prospects for engineers in these new possessions. These letters usually come from young engineers, ambitious to force an opening for themselves and anxious to be among the first in the field. While approving of the spirit which prompts this movement, we would advise considerable caution in carrying out the contemplated scheme of seeking professional employment in these remote lands. There is undoubtedly abundant need for engineering enterprise in all of the one-time Spanish possessions; but time must elapse before the conditions are ripe for any radical change of methods which would call for active engineering work. Stable government must be established before capital from the United States will seek investment in these islands; and the people must be made to understand that the misrule of past centuries is at an end before they will be ready to accept and appreciate new methods and new ideas. This means the displacement of well-rooted old ideas; a period of change; and possibly of conflict between the old and the new, which may consume a long time. In this coming revolution in these new possessions, the engineer is doubtless one of the most important factors; but money is absolutely necessary to carry out engineering works, and the conditions must first be such that there is reasonable safety for the investment of money. Our advice to such young engineers is, therefore, to watch capital; to connect themselves at home, whenever this is possible, with those who propose to furnish the means to build engineering works in our new possessions; and to follow the capitalist, and not to precede him. Any other course would probably mean a disheartening struggle, a long wait under unfavorable circumstances, and disappointment. We say probably, because in any field there is usually a chance for a man of exceptional ability and energy or experience; and such a man—on the ground, might find the means for inducing capital to follow him to our new territory. But a man of this type would also succeed equally well at home, where the chances are quite as abundant and the ruling conditions are more favorable. As to the Hawaiian Islands, we would warn our correspondents that American engineers have been for years established there, and at the present time, at least, the supply exceeds the demand. Within a few years, and with the aid of American enterprise, capital and administrative methods, we confidently look for a marked economic advance, in the two West Indian Islands especially; and for the building of railways and highways, improvement in water supply and the sanitation of towns, and in the development of the enormous agricultural wealth of these islands; in other words, there will sometime be abundant work for engineers and a large market for those supplying engineering materials. But while the field is now open for the careful study of engineering possibilities by the experienced man of affairs and engineering expert; the conditions are not yet ripe for the employment of the young engineer who has his experience yet to gain. His chance will come later; when the time arrives for carrying out the plans formulated by the pioneers in the new field.

◆

The recent promotions of the naval officers who participated in the engagements at Manila and Santiago, while well deserved by these officers, have unfortunately done injustice to other officers. By advancing the list numbers of the promoted officers those who are not promoted and who are thus "jumped over" suffer a loss of numbers just as if they had been punished in that manner for some crime or offense against the naval regulations. In many cases an officer who loses some numbers by having other men advanced over him loses his chance of gaining the higher grade and higher pay which he reasonably expects to receive before reaching the age of retirement. It is stated in a press dispatch that Secretary Long will ask Congress to pass a bill to reward brave officers with a medal of honor and an increase of pay of 10 per cent for life, but it is understood that this bill is designed wholly to affect subsequent cases and not to correct the injustice already effected by the promotions. It is to be hoped that the Navy Department may devise some plan, which Congress may approve at its next session, by which the heroes of Manila and Santiago may receive proper rewards without inflicting injustice upon men equally brave but who did not have the same opportunity to show their bravery.

THE SUCCESS OF THE DETROIT MUNICIPAL ELECTRIC LIGHTING PLANT.

The city of Detroit, as most of our readers will recall, has made the largest venture in the way of a municipal electric lighting system of any city in the United States.

The subject of municipal lighting has been extensively discussed and bitterly fought over during the past ten years. Advocates of municipal ownership have magnified the savings which they claimed would be made when cities ceased to rely on private companies to light their streets. The opponents of municipal ownership, on the other hand, have urged that the loss through incompetent and dishonest officials and employees, in the case of municipal plants, would leave the taxpayer in a worse state than when lights were secured by contract.

*Exclusive of Belle Island.

It is of no small interest, therefore, to see just what results are obtained in practice and see how they compare with those which were so confidently predicted a few years ago. The third annual report of the commission in charge of the Detroit lighting system is before us. It covers the year ending June 30, 1898. As this is the third year of the plant's operation, it may be safely assumed that it is now on a fairly permanent basis. Both machinery and employees are well broken in, and the plant is old enough for the item of repairs and renewals to represent something like a steady figure.

To give first a little of the past history: The Public Lighting Commission of Detroit was created by the Michigan legislature in March, 1893. Its six members were appointed by Mayor (now Governor) H. S. Pingree, with the approval of the city council, and under their direction plans and specifications were prepared and contracts were let for a new municipal street lighting system. The first annual report of the commission, describing the construction of the plant, was reviewed in Engineering News of Aug. 13, 1896.

Turning now to the report of operations for the third fiscal year, let us consider first the cost of the plant.

On June 30, 1897, the total cost of the entire plant, excluding the Belle Island plant ($7,821), amounted to $721,400, or an investment of $337.88 per arc lamp and $18.93 per incandescent lamp, there being at that time a plant capacity of 2,000 arcs and 3,000 16-c. p. incandescent lamps. For the fiscal year ending June 30, 1898, the figures for the same items, also excluding the Belle Island plant ($18,848), are: Total cost, $771,297; investment cost per arc lamp, $293.69; per incandescent, $18.52; using the maximum capacity figures of 2,250 arcs and 3,500 incandescents.

It may be said here that the investment in machinery, etc., which is included in the above total comprises 7 Peck boilers, 5 triple-expansion engines of 240 to 340 HP., 20 arc dynamos of 50 K-W. capacity each, 2 57½ K-W. arc dynamos, 3 Westinghouse engines, 3 55-K-W. two-phase incandescent dynamos, 1,842 arc lamps, 3,901 incandescent lamps, 5,210 poles and 394 miles of wire, and all auxiliary apparatus such as pumps, condensers, feed-water heaters, etc.

In Table I. the figures for investment, output, etc., are given for both 1897 and 1898. It will be seen that the investment per lamp has been considerably reduced through the extension of the lighting system with little or no increase in the power station machinery, and that the operating expenses have been largely reduced. Table II. shows that the economy has been chiefly effected in the item of maintenance, and in shop expense, and the various items in the table will repay careful study by those interested in electric station economy. In Table III. the operating expenses have been arranged as percentages of a total.

It will be seen that station operation and the items connected with maintaining and operating the lamps made up 66.48% of the total operating expenses during 1897, and 74.11% during 1898, or an increase of 7.63%, which was accompanied by a corresponding decrease in other departments. The total operating expenses given in Tables II. and III. show a decrease from 3.696 cts. to 3.038 cts. per K-W. hour of output. There was an increase for 1898 over 1897 in total output of 301,203 K-W. hours to operate 180 arc and 837 incandescent lamps installed during the year.

TABLE III.—Percentage of Operating Expenses of the Detroit Municipal Lighting Plant, Charged to Each Department.

Department.	1897. Wages.	1897. Stores.	1897. Total.	1898. Wages.	1898. Stores.	1898. Total.	Difference in totals.
Maintenance	15.13	4.45	19.58	11.84	4.51	16.35	3.23†
Executive	8.06	.96	9.02	7.69	.83	8.50	52†
Station	18.95	18.09	37.04	22.07	20.14	42.21	5.17§
Trimming	21.61	7.83	29.44	22.07	9.83	31.90	2.46§
Shop	4.13	.60	4.73	.51	.20	.71	4.02†
Injuries & damgs	.01	.18	.19	...	.33	.33	.14§
Total	67.89	32.11	100	64.16	35.84	100	....

†Decrease. §Increase.

It will be seen that the above figures do not give the total cost per lamp per year, which is the basis on which figures for street lighting are most frequently compared. We will ascertain this a little later; but first let us see what arc lamps cost the city when it secured its light by contract.

The average number of arc lamps actually operated and the cost for each year from 1884 to 1894 is given in Table IV., which is reprinted from the report of the Commission for 1896.

TABLE II.—Operating Expenses for 12 Months Ending June 30, of the Detroit Municipal Lighting Plant.

Charged against	1897. Total.	1898. Total.	1897. Per K-W. hour.*	1898. Per K-W. hour.†	Difference, Per K-W. hour.

TABLE IV.—Number of Arc Lamps and the Cost to the City From 1884 to 1894.

Year.	Total No. of lamps.	Paid to companies.	Average per lamp.
1884................	24	$3,650	$152
1885................	300	71,982	240
1886................	382	91,571	240
1887................	565	115,490	204
1888................	608	117,370	193
1889................	702	128,063	182
1890................	719	137,937	192
1891................	1,031	133,717	130
1892................	1,168	152,283	130
1893................	1,279	164,831	129
1894................	1,279	169,360	132

In April, 1893, bids were asked for lighting the city for periods of from one to ten years. The bids submitted by the local electric lighting company ranged from $154 per lamp for one year to $102.20 per lamp for ten years; $124 being the price asked for five years. If the ten-year agreement had been entered into, and if the number of lamps had increased at the same rate that actually did occur, Table IV. should receive the following addition:

Year.	No. of lamps.	Addition, total cost.	Cost per lamp.
1895................	1,297	$173,538	$133.80
1896	1,483	151,562	102.20
1897................	1,564	159,804	102.20
1898................	1,744	178,236	102.20

In ascertaining the present actual cost of Detroit's street lighting, it is necessary to consider the matters of interest, taxes and depreciation, which are not included in the figures given in Tables II. and III.

The two previous reports of the commission have both been justly criticised because in their computation of the cost per lamp these items were not sufficiently considered. Thus in the first year's report, interest on the bonds issued to build the plant was included, but no mention was made of taxes or depreciation. In the report for the year ending June 30, 1897, interest and taxes were fairly estimated; but depreciation, for some inscrutable reason, was figured on the boiler plant alone.

In the 1898 report, however, all three items are included, and we find figures as follows:

Interest at 4% on $750,000, which is taken as the average investment.	$30,000
Depreciation at 3% on $750,000..........................	22,500
Taxes at $17.68 per $1,000 for city and $3.24 per $1,000 for state on $400,000, the estimated assessed valuation	8,368
Total	$60,868

This, proportioned on the basis of electrical output, gives $55,207 chargeable to arc lighting and $4,660 to incandescent lighting. Dividing the amount chargeable to arc lighting by the number of arc lamps (1,744), gives a cost of $31.65 per lamp per year. Adding this to the operating expenses of $51.85 per lamp per year and we have $83.50 as the total cost to Detroit per arc lamp for the year ending June 30, 1898.

Does this represent fairly the actual cost to the people of Detroit, so that we can fairly compare this figure with the figures for contract service given above, or with the amount which other cities pay for electric lighting?

Concerning the operating expenses, it will be generally agreed that these fairly represent the actual cost of running the works. The only thing which appears at all doubtful is whether the saving in maintenance account has not been made by putting off to a more convenient day repairs and renewals, which ought to have been made to keep the plant in good condition. If this is the case, however, it will show in the expense accounts a year or two hence. The interest estimate is certainly fair, as the city can certainly borrow money at 4%, the rate named. The tax allowance, too, will hardly be questioned by even the most rabid opponent of municipal ownership. When we come to the item of depreciation, however, dispute is sure to arise. Partisans of electric light companies will assert, we presume, that 7% to 10% is the least that should be allowed; and will instance the depreciation which has been experienced in every electric light station established prior to 1890 through the advent of improved machinery. But the past is not always a safe guide to the future. It is true that much of the machinery of ten years ago is obsolete now; but it is by no means certain, or even probable, that the same radical revolutions in electrical industry will be effected in the ten years to come. There was a time when progress in steam engine design was exceptionally rapid, and the old throttling low-speed engines were fast made obsolete by the automatic cut-off engines of the Corliss type. But at the present time there are many engines running which were built before 1880 and doing excellent and economical service too.

Let us see what a 3% allowance for depreciation means. It means that if 3% of the cost of the plant is laid aside each year and invested in a sinking fund, with interest at 4%, then at the expiration of between 21 and 22 years that fund will have accumulated to an amount equal to the cost of the plant. Of course, the plant itself will not be valueless at that time. A considerable part of it will be worth nearly as much as to-day, but we may fairly offset the value which it will then have against the increase in the cost of repairs which may be expected as the plant grows older.

Now, the question is whether 21 years is too long a time to set for the average life of the plant. We are inclined to think that it is, and that a depreciation allowance of 4%, corresponding to an average life of a little less than 18 years, would be a more accurate estimate to determine the actual cost of electric light in Detroit.

There is one other item which ought to be included in the Detroit plant's expense account to determine the actual cost, and that is insurance. True, the city does not insure the plant, and we do not question its wisdom in adopting this course. Nevertheless, the element of risk of loss by fire is as much an item in the cost of producing electric light as it is in any manufacturing industry.

Suppose we allow an extra 1% for depreciation and 1% for insurance on the investment of $750,000, this will add $15,000 to the annual expenses, and will make the total cost per arc lamp per annum, $92.10.

It will be seen from the above that Detroit is certainly effecting considerable saving over what she would have expended had she accepted the bid of $102.20 per lamp, which was made in 1893 by the Detroit lighting company for a ten-year contract. A saving in round numbers of $10 per lamp per year means $17,440 per annum with the present number of lamps. On the other hand, it seems to be clear that the company, in making its bid, named about as low a figure as it could afford and leave itself a profit that would make the business worth doing. The company would have had to pay probably 6% interest as compared with the city's 4%, and it would have had to meet the contingency of failing to secure a renewal of the contract at the end of ten years, which would have left its plant on its hands. Thus it would have been obliged to figure on a much higher rate of depreciation than the city.

TABLE V.—Average Cost of Arc Street Lighting in Each State.

State.	Hours per year.	Coal per ton.	Cost per lamp Per year.	Cost per lamp Per hour.
Alabama	4,000	$1.92	$89.00	$0.021

TABLE VI.—Cost of Arc Street Lighting in Principal Cities of the United States.

Cities.	No. of arc lamps.	Hours per yr.	Coal per ton.	Contract per lamp per yr.	Cost pr lamp-hour.
Indianapolis, Ind.	1,100	2,179	$1.25	$85.00	$0.039
Louisville, Ky.	1,219	3,840	1.00	84.00	.022
New Orleans, La.	1,384	4,000	2.38	127.50	.032
Boston, Mass.	2,566	4,000	4.00	127.75	.032
St. Louis, Mo.	2,500	4,000	1.35	74.95	.019
Jersey City, N.J.	1,075	4,000	2.50	99.00	.025
Newark, N. J.	1,565	4,000	1.70	98.55	.025
Brooklyn, N. Y.	3,382	4,000	3.60	124.10	.031
Buffalo, N. Y.	2,500	4,000	2.00	100.00	.025
New York city	3,643	4,000	....	146.00 164.20 182.50	.037 .041 .045
Rochester, N. Y.	2,248	4,000	Water.	91.25	.023
Syracuse, N. Y.	980	4,000	2.25	91.25	.023
Cincinnati, O.	1,510	4,000	2.00	84.90	.021
Allegheny, Pa.	1,037	4,000	.95	74.31	.019
Philadelphia, Pa.	6,500	4,000	2.50	109.00 146.00	.027 .036
Pittsburg, Pa.	1,900	4,000	1.01	96.00	.024
Providence, R. I.	1,800	4,000	....	127.75	.032
Salt Lake City	4,000	4,000	2.75	72.00	.018
Milwaukee, Wis.	718 444	4,000	3.00	92.00 109.00	.023 .027
Detroit, Mich., '98	1,744	3,786	1.97	83.50	.022

On the other hand, the company would have had the great advantage of doing commercial as well as street lighting; and this it seems to us is the weakest point in the operation of the Detroit municipal plant. It is evident on the slightest thought that to furnish electric light to a town or city, at the least possible cost, one concern should undertake both the public and private lighting.

As it is, the city of Detroit appears to be getting its street lighting done more cheaply than any private company would undertake that work unless it were guaranteed a monopoly for a long term of years. Comparison with the prices paid in other cities also results in a favorable showing for Detroit. Table V. is prepared from data given in a circular issued by the General Electric Co., of Schenectady, N. Y., and is interesting in this connection. The prices given are for the winter of 1897, and are averages of practically all the arc lighting plants owned by private companies in the states given.

Comparing the Detroit figures with the average for the 1,045 electric light plants whose operations are covered by Table V., it will be seen that in Detroit the hours per lamp were greater, the cost of coal less, the cost per lamp per year less and the cost per lamp hour considerably less than the average of all stations reporting.

A still more interesting comparison may be made between Detroit's prices and the prices charged in other large cities of the United States, as given in Table VI.

In this table New Orleans, La.; Newark, N. J.; Buffalo, N. Y., and Cincinnati, O., operate practically the same number of lights as Detroit, and coal costs about the same per ton with them. All, however, with the exception of Cincinnati, pay considerably more per lamp per year. In only three cities, St. Louis, Mo., Allegheny, Pa., and Salt Lake City, is the cost per lamp less, and in these cities coal is considerably cheaper than in Detroit.

LETTERS TO THE EDITOR.

The Title of U. S. Assistant Engineer.

Sir: Several days ago I read the editorial in Engineering News of Aug. 4, on "The Position of United States Assistant Engineers," with much interest. If suggestions are in order, permit me to make one at this late date. It seems to me that the government, or "powers that be," might at least substitute the title "United States Civil Engineer," in place of "U. S. Assistant Engineer." The term "Assistant Engineer" is used by many railway and municipal engineering departments to designate transitmen, levelers, draftsmen, or even rodmen. Hence, among civilian engineers, the title "Assistant Engineer" has come to mean a person holding some such minor position on engineering work.

Of course the term "U. S. Civil Engineer" would not indicate the specialty of an expert, but it would indicate the department of engineering, in contra-distinction to the titles, "U. S. Mechanical Engineer," "U. S. Electrical Engineer," "U. S. Mining Engineer," which likewise seem to me to be very appropriate titles for official use.

Very respectfully yours,
C. E. Sherman,
U. S. Assistant Engineer.
Camp Wheeler, Huntsville, Ala., Aug. 26, 1898.

◆

Large Cast-Iron Wheels for Cars and Engine Trucks.

Sir: We have just noticed in your valuable paper of June 9, an article on "Locomotive Tender and Truck Wheels," in which the statement is made that one reason why American locomotives generally have small wheels is that they are fitted with cast-iron wheels, and it is not easy to make good chilled cast-iron wheels of greater diameter than 33 ins., although some foundries have attempted to cast 42-in. wheels, but with unsatisfactory results.

As we have been making wheels 40 ins., 42 ins., and even 45 ins. in diameter for the past five years, we are a little surprised at the statement, and take this opportunity of advising you of what we have done in making wheels of large diameter. We find from our records that in the last three years we have furnished 356 wheels 40 ins. diameter, 84 wheels 42 ins. diameter and two lots of 45-in. wheels; the 42-in. wheels have been used under both passenger cars and engines, and as we have had two repeat orders for those running under engines, we judge that the service has been entirely satisfactory.

We think we are the only wheel makers in the country who have ever successfully made double-plate wheels 45 ins. diameter, and as these have now been running for over a year under locomotives, we can assume that they were a success. Very truly yours,

New York Car Wheel Works,
Pemberton Smith, Engineer.
Buffalo, N. Y., Aug. 29, 1898.

(It is interesting to note that such large chilled wheels have been made, but it will be seen that the number is quite small and that they have only been made within the past few years. Their manufacture and their use on engine trucks are certainly exceptional as yet. Whatever may be the present conditions of manufacture, we believe the above letter does not in any way affect our suggestion (which was based upon investigation) to the effect that one reason why the smaller wheels have been so generally used on engine trucks is that there are greater difficulties in the manufacture of the large wheels. We have very good authority for our statement that some of the early attempts to cast 42-in. wheels produced unsatisfactory results.—Ed.)

◆

Spacing Stiffeners in Plate Girders.

Sir: The letter of Mr. Jos. M. Wilson on "Spacing Stiffeners in Plate Girders," published in your issue of Aug 11, does not seem to me to be conclusive; neither do the photographs of the loaded paper model seem to offer "convincing proof" that the web resists by tension only. This was quite thoroughly gone over in the discussion brought out by Mr. Wilson's paper by Prof. W. H. Burr and Mr. Edwin Thacher.* Cutting slits in the web entirely changes the conditions; just as would be the case with a Warren girder of two or more systems of web members, if one of the systems were cut.

The distortions in a plate girder under load are of a nature that do not appear to offer much room for difference of opinion. Consider, for simplicity, one panel included by two stiffeners. The top flange will shorten and the bottom flange will lengthen under the compressive and tensile stresses respectively. Then, considering the tension in the web, the panel will be lengthened or stretched out on the diagonal of the tensile stress, and this cannot possibly take place without a corresponding shortening of the opposite diagonal. The effect of stress on a cross section of the member perpendicular to the line of stress, if not confined, is manifested in both directions, width and thickness; so in the case under consideration only a part of the required shortening could possibly be due to this effect of the tensile stress. Therefore, the web will either buckle or be compressed by compressive stress. Since they do not buckle in ordinary practice the diagonal compressive stress must exist in the web.

I am not prepared to deny that the vertical stiffeners carry some proportion of compressive stress in girders as usually built, even when not subjected to concentrated loads, but where there are two or more courses for a stress to follow (a condition of ambiguity), it will divide itself inversely as the length of the course and directly as the section of the members. In other words, it seeks the shortest course and strongest members.

Since flexure (or buckling) does not ordinarily occur in the webs of plate-girders under service, the relative strength of the webs and stiffeners within the limits of working loads are directly as their sectional areas. In most cases the section of the web is much greater that that of the stiffeners. Therefore, if ambiguity does exist, the web offering the shortest course and strongest section will carry far the greater part of the stress, in accord with Rankine's theory.

---

*Trans. Am. Soc. C. E., Vol. XV., 1886, pp. 431 and 468.

If someone who has the facilities would apply an extensometer to a plate girder, this question would be placed beyond discussion, to the benefit of all interested.

Albert W. Buel.

150 Broadway, New York, N. Y., Aug. 15, 1898.

Sir: I note with interest Mr. Jos. M. Wilson's contribution to the discussion on the stiffening of web plates, in your current issue. It requires but little reflection to recognize, however, that the behavior of the paper model is strictly in accord with the generally accepted theory governing the distribution of stresses in web plates.

It is to be remembered that the principal stresses—tensile and compressive—act at right angles to each other at every point in the web plate, and that their lines of action intersect the neutral plane at angles of 45°. The general appearance of these lines of principal stress is shown in Rankine's Applied Mechanics, p 342; also in Merriman's Mechanics of Materials, p. 160, although the lines are not completely drawn in the latter. The most complete discussion, known to the writer, covering this matter of internal stresses in beams, is found in Weyrauch's "Theory and Calculation of Continuous and Simple Beams (1873)," pp. 11 to 20, inclusive, illustrated by excellent diagrams, shown on Plate I., in which the lines of principal shears are, however, incomplete. It is to be observed that all diagrams here referred to, relate to beams of solid rectangular cross-section, and require some modification for flanged girders. The distribution of shear across the web of a plate girder is much more nearly uniform than in the case of a rectangular section without flanges.

From the inspection of any of these figures, it will be evident at once that when the web is cut, as in Mr. Wilson's model, and the latter placed in a position relative to a central load, as in Fig. 2, the continuity of all lines of principal tensile stress is absolutely interrupted at the diagonal slits. Not only can these tensile stresses no longer be properly developed, but in their absence or very imperfect state of development, the tendency of the principal compressive stresses to produce buckling in the web can no longer be effectively opposed. The distortion shown in Fig. 2 becomes, therefore, inevitable and might, in fact, have been predicted from purely theoretic considerations.

In Fig. 1, on the other hand, the principal tensile stresses remain, for the most part, fully operative, although, in this case also, their continuity is, to some extent, broken. It is to be expected, therefore, that, contrary to Mr. Wilson's statement, the web thus conditioned will develop less ultimate strength than if left continuous.

It may be observed, in conclusion, that the step from such a model, however its behavior may be explained, to a claim for the analogy between the stiffeners of a plate girder and the posts of a Pratt truss, is one that can be taken only in absolute defiance of sound theory.

Very respectfully, E. M.

Philadelphia, Pa., Aug. 17, 1898.

Sir: In your issue of Aug. 11 the writer has noted a very interesting communication on the plate girder by Mr. Joseph M. Wilson. The paper model is highly ingenious, illustrating how much better able a thin web is to resist tension than compression along the diagonal of a panel. Cutting the slit, however, prevents the tensile stress from stiffening the web, somewhat under compression, as it ordinarily would.

About a year ago the writer was furnished with a model plate girder by the Gillette-Herzog Mfg. Co., through the courtesy of Mr. Frank J. Llewellyn, Chief Engineer. This girder was built in accordance with the writer's design, and is shown in Fig. 1. In alternate panels the web plate was buckled ⅝-in. before assembling in the form of a very flat pyramid, with the corners rounded off; the edges of the pyramid forming the diagonals of the panel. Evidently were the web stresses, tensile and compressive, distributed as in a beam of constant section, the lateral components of these tensile and compressive stresses would neutralize each other, and the form of the buckle should remain unchanged as the load is applied or removed. If on the other hand there is truss action and the tensile stress is the greater, the buckle should spring in as the load is applied.

Under twenty-eight tons this spring of the buckle was about ⅛-in. and the buckle returned to its original shape as the stress was removed. The load was applied by the screw lever at one end and weighed off at the other. The spring of the buckled web seemed to be the same in the end panel, and the panel next the center, as would be expected, since the shear was the same in each.

Having thus shown that a part of the load is carried in a manner similar to a Pratt truss, the question of how great a part naturally arises. In the design of the experimental girder, by a rough method, the writer figured that a trifle more than two-thirds of the load would be carried in a manner similar to a Pratt truss, and the top and bottom flanges were proportioned accordingly. Thermo-electric measurement of the chord stresses indicated that the results arrived at in designing represented closely the actual conditions. Whether the writer would be equally successful in other and different cases he has not as yet had opportunity to determine. As a further proof of the truss theory, all stiffeners were found to be in compression.
